Mr. JUSTICE A. L. SMITH: I do not understand this. I do not know if it is necessary for me to, but £5,000 was paid to the British Electric Light Company, for what?

Sir HORACE DAVEY: They made some claims, my lord.

Mr. JUSTICE A. L. SMITH: To forego a claim, he said, not a legal one, and they got from him some letters which they said gave a claim on his patent.

The WITNESS: Yes. The whole of the £5,000 went to the British.

But nothing of that came to you?—Not a penny, my Lord. Shares were paid to me by the Brush Company—shares with a very large liability, but with a considerable amount credited as paid up.

When in practice in lighting by electricity did they begin to work these reservoirs somehow as you have described, by switches, and so on?—Not much until 1882, my Lord. The whole of my attention in the earlier days was occupied in developing the details of the lamp itself and I had no time to devote myself to that part of the system.

I understand you took out a patent for your lamp in 1878, and then worked at the lamp?—Almost exclusively.

When in electric lighting anybody other than yourself commenced to work what I may call your battery system?—No one, my Lord; I was the first to put them in practical operation.

After 1881 who began to put them into practical operation?—I began with the Electrical Power Storage Company. I was instrumental in bringing about the existence of that Company.

Tell me, for my own information, what was going on during 1883 to 1890.—The system was well started, and was worked at by a great number of individuals and companies.

Did they put up your reservoir system, I mean?—Yes, my lord.

Did you get royalties for that, or let it slide?—I did not let it slide, my Lord, but I was powerless.

Why?—Because I could not control my patents, and the Brush Company was involved in other litigation, and the whole matter is very complicated.

Sir HORACE DAVEY: Does it come to this: the Brush Company did not think it worth while, nor did they even ask for royalties?—Yes, they began an action against the Edison-Swan Company. That was the one that was compromised; but it lasted several years. There was an action exclusively on this patent against the Edison and Swan.

Mr. MOULTON: The Brush Company had divided interests.

Sir HORACE DAVEY: They commenced the ball by an action on Edison's patent?—Yes.

And this was a counterblast?—I suppose it might be regarded in that light.

And resulting in a general peace all round?—Yes.

Mr. JUSTICE A. L. SMITH: Can you tell me when that general peace came—the year?—At the end of 1889.

Sir HORACE DAVEY: It never came to trial?—It never came to trial. I was, of course, very much aggrieved at it.

But the Brush Company's advisers took a different view?—Not as to the validity of the patent; and, as you have asked me the question, I may say that General Webber, who was Managing Director of the Brush Patent Company, has stated publicly that he considered my patent as good as any they ever had anything to do with.

I think in 1881 there was an Exhibition in Paris?—Yes; I exhibited with the Brush Company for the purpose of showing incandescent light. That installation had no storage batteries. The fittings were made in London on the plan using only one insulated wire—but the French people would not have the uncovered copper wire. They insisted on having an insulated return wire. I pointed out in my patent what many would know, and some would not know, that the insulation of the return conductor was superfluous,

In incandescent electric lighting?—Yes, in incandescent electric lighting.

And you still retain that opinion?—I do, emphatically.

Now the only secondary batteries which were shown at the Paris Exhibition were by Faure, were not they, and they were shown in the ordinary manner in which storage batteries are used?—I really do not know what you mean.

For the purpose of storing up electricity and then utilising the electricity from the accumulator?

Mr. MOULTON: They were not used as regulators?—That I am not sure of. It is quite possible they were. I am not sure of their connection.

Sir HORACE DAVEY: At any rate, you had nothing to do with Faure's exhibition?—No, I had not directly, of course; the work I had done in incandescent lighting had a deal to do with it.

Mr. JUSTICE A. L. SMITH: There were no batteries?—No, not in my installation.

Did you get a constant light without the batteries?—No, we did not; it was a source of trouble.

Sir HORACE DAVEY: Now why did you not exhibit? You very properly said you wanted to push your system—this wonderful invention which the Attorney-General has described to us—at the Paris Exhibition?—As I have already told you, all my energies were taken up in producing the necessary incandescent lamps for that Exhibition.

That I quite agree with; but, remember, you had taken out this patent in the year 1878, and the Paris Electrical Exhibition was a great opportunity of introducing a new system to the electrical world.—Yes, I should have been delighted if they allowed me; but the Brush Company prevented me putting up a great deal I wanted to, and among other things they prevented me making this installation as complete as I should like.

Now, sir, will you definitely pledge your word that the Brush Directors prevented you from putting up secondary batteries in Paris?—I do not know that the matter was raised, but the matter was put in my hands, and I was limited as to funds.

The witness was then cross-examined at considerable length on the patents of Clark and Achard.

Sir HORACE DAVEY: I think you made a declaration on the disclaimer of these second disclaimer proceedings?—Yes.

And I think you admitted on Friday, when the secondary batteries were being charged there was what the Attorney-General described as a curve from rapid at first, and then more gradual, and then more rapid, you remember that?—Yes.

And I think you said that it was not right, or that any person of common sense—I do not know whether you meant any person of common sense in 1878—would not charge the batteries fully, completely?—I said, overcharge them. If you remember there was a great deal of talk as to what was "full."

No, I beg your pardon. By "full" I mean full. When I say a bucket of water is full, I mean full—not half-full.—Yes, but there is a difference between a bucket of water and a secondary battery—the analogy is very erroneous.

What I understand to be full is to the bubbling point.—Well, I do not. I call that over-full. You see it depends on the purpose for which you are using batteries. The boiling point of the batteries is an excess charge. It is necessary for forming the batteries, but it is not necessary for the purpose of storage or regulation—it wastes energy.

I will not say any fool, but any person of common sense, any electrical workman, would have known that in 1878.—No, not any electrical workman; he must have had some acquaintance with secondary batteries which he could have acquired. Telegraphists were ignorant of a great many matters connected with dynamos in 1878, yet they called themselves electricians. I quite think the word "fully" was rather an exaggeration—full for the purpose—"sufficiently" would have been a more correct expression.

You see you say "fully." Do not you think that is calculated to convey the idea to the mind of any person that what you meant was charging the batteries till they were full?—Yes, but do not you see there is a difference between us as to what "full" means?

The cross-examination of Mr. Lane Fox was continued, and questions were asked on statements made in a lecture by him at the Royal United Service Institution, and on another occasion at the then Society of Telegraph Engineers on April 14, 1881. Letters were put in by counsel, showing that the defendants had refused to allow the plaintiff to make a complete inspection of their system. The re-examination was begun on Monday afternoon, and was concluded soon after the Court sat on Tuesday. Prof. Silvanus Thompson and Prof. Barrett gave evidence on that day, and the case for the plaintiff was closed after the evidence of Prof. Forbes. Sir Horace Davey began to open his case for the defendants in the course of the afternoon, and continued throughout the sitting on Wednesday. A very elaborate model was exhibited, with the intention, apparently, of showing the great complexity of the defendants' system, as compared with the simple claim of the plaintiff. A careful abstract of the shorthand notes will be given in our next issue.

Allison v. City and South London Railway Company.

In the Chancery Division on Tuesday the case of Allison v. City and South London Railway Company again came before Mr. Justice Kekewich. This was an action brought by the surviving trustees of the Stockwell Orphanage against the defendant Company to recover damages for an alleged nuisance arising from the noise and vibration caused by the working of the defendant Company's engines and dynamos close to the girls' wing of the Orphanage. The case first came before his lordship last spring, when it was adjourned to enable the defendant Company to execute certain alterations with the view of putting an end to the nuisance.

Digitized by Google

The defendant Company made certain alterations, which, however, did not satisfy the plaintiffs, and on the case coming before his lordship a fortnight since, he directed that Mr. Harris should visit the orphanage and the defendant Company's works, and make a report to the Court as to the true state of affairs. Mr. Harris now presented his report to the Court. It was to the effect that the defendant Company's engines did cause such a nuisance and vibration as to interfere with the enjoyment of the occupants of some of the houses at the Orphanage, and that everything had not been done to put an end to the nuisance. Mr. Harris was of opinion that it would not be unreasonable to request the Railway Company to lessen the nuisance by removing their engines to another part of the building. In answer to his Lordship, Mr. Harris said the defendant Company could place and work their engines at a distance of thirty or forty yards from any other person's property; but whether such an alteration would interfere with the satisfactory working of the railway he was not prepared to say.

Mr. COZENS HARDY, Q.C., on behalf of the defendant Company, submitted that the matter now resolved itself into a question of law. Parliament, he said, had authorised the making of the line to be worked by electricity, and although it might sometimes occasion a nuisance to persons residing in the neighbourhood of the works, the defendants were relieved from all liability unless it could be shown that they had been guilty of negligence in the manner in which they had carried on their business.

Mr. RENSHAW, Q.C., for the plaintiffs, denied that the Act authorising the construction of the line permitted the defendant Company to do that which was complained of by his clients.

His LORDSHIP, in delivering judgment, said he was of opinion that the defendant Company had now set themselves right, although they might have been wrong originally. He was bound to say that the Company had done all that could reasonably be required of them. The Company, however, would have to pay the costs of the action up to December 31st last, and he also thought they ought to pay damages, which he would fix at £50. The costs of the inspection by Mr. Harris would have to be divided between the plaintiffs and the defendants.

Freter v. Metropolitan Electric Supply Company.

In the Chancery Division, on Wednesday, Mr. Justice Chitty had before him the case of Freter v. Metropolitan Electric Supply Company (Limited), which was an action brought by Mrs. Freter, the owner of the John Gaunt Tavern, Lincoln's Inn, against defendant company to recover damages and an injunction. The plantiff's case was that the defendants' works were adjacent to her house, and that the vibration caused by the working of their machinery had damaged her property and was a nuisance. The defendants denied that the vibration was caused by the working of their engines. In the alternative they submitted that they were protected by the Electric Lighting Acts.

Mr. Byrne, Q.C., and Mr. Sebastian appeared for the plaintiff; while Mr. Lockwood, Q.C., Mr. Latham, Q.C., and Mr. Butcher represented the defendants.

After some evidence had been called, the parties effected a compromise, the terms of which were not mentioned in court.

Latimer Clark, Muirhead and Co. v. Francis.

In the Court of Appeal on Saturday last, the case of Latimer Clark, Muirhead and Co. v. Francis came before the Master of the Rolls, and Lord Justice Lopes and Lord Justice Fry, in the form of an appeal by the plaintiffs from the decision of Mr. Justice Grantham, who had entered a judgment of nonsuit.

Mr. Lawson Walton, Q.C., and Mr. Burdon appeared for the plaintiffs in support of the appeal, while Mr. Whitehouse opposed on behalf of the defendant.

Mr. LAWSON WALTON, in support of the appeal, said the action was brought by the plaintiffs, who were electrical engineers, claiming an inquiry whether the defendant, Col. Francis, had been allotted more than his proportion of founders' shares in the St. James's and Pall Mall Electric Lighting Company. At the trial before Mr. Justice Grantham, without a jury, his lordship held that the plaintiffs had disclosed no cause of action, and entered a judgment of nonsuit. The plaintiffs now appealed against that decision.

Their LORDSHIPS, without calling upon the learned counsel for the defendant, dismissed the appeal with costs.

Moorgate Street and Broad Street Building Company (Limited) v. Exchange Telegraph Company (Limited).

This case was heard in the Queen's Bench Division on Saturday last, before Mr. Justice Day.

The plaintiffs are the owners of a block of buildings known as 52 and 60, Queen Victoria-street, in the City of London; and they alleged that the defendant Company, by their servants, wrongfully affixed certain telegraphic apparatus and wires to the roof and chimneys of the buildings, and that the defendants refused to remove them when required. They claimed £100 damages. The defendants denied any wrongful entry or trespass, and stated that they obtained leave and licence from the plaintiffs or from their predecessors in title, and that they removed the wires within reasonable time. They further paid £5 into court as sufficient to satisfy any claim of the plaintiffs. Evidence was called on behalf of the plaintiff Company in order to show that it was usual to pay a rent for affixing wires. —Mr. Higgins, engineer to the defendant Company, proved having obtained leave to put the wires up from the former secretary of the plaintiff Company. It was not usual to pay a rent.

Without calling upon Mr. Shearman for the defence, his LORDSHIP said he was quite satisfied that the defendants had committed no trespass, and that they were quite within their rights. They had in their letter declined to pay damages, and asked for reasonable time to allow them to remove the wires. They were quite within their right, having obtained leave to fix them. The plaintiffs would not allow them reasonable time, but would insist upon bringing this action. The defendants had paid £5 into court, and he found that quite sufficient for the rental for the time they had occupied the roof of the premises; and he therefore gave judgment for the defendants, with costs.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *February* 19, 1892.

The Thomson-Houston-Edison Consolidation.—The great topic of interest just now is the Thomson-Houston-Edison Consolidation, and about which there are divers opinions. This much is certain, that the arrangements are practically completed, although there is no formal reorganisation as yet completed. It is going on rapidly, however, and presently formal action will be taken. It seems the general impression that the Thomson-Houston Company has decidedly the best of the bargain; but this idea is probably largely owing to the fact that in the offices of the Edison Company there is considerable demoralisation, the occupants not knowing whether they are to stay or go. As a matter of fact the changes are likely to be principally in the district offices, where until now two complete working staffs have, of course, been in existence. These are now rendered unnecessary, and there is a strong likelihood that they will soon be amalgamated, dispensing with the less useful men. The businesses are so large and growing so rapidly that there is plenty of work for a very large force, and it is altogether likely that only inefficient and incompetent men will find themselves out of a job. There has been a good deal of incompetence in some departments of the Edison Company lately, and under the reorganisation steps will be taken to bring the whole force of the consolidated company into good working order.

The Buffalo Meeting of the National Electric Light Association.—The meeting of the National Electric Light Association will take place at Buffalo on Tuesday, Wednesday, and Thursday of next week, and a large attendance is promised. This present convention bids fair to be well attended and to be very business-like in character. Heretofore a good deal of energy has been wasted in elaborate and costly electrical exhibitions, and in junketing that might well be applied to furthering the common interests of the members of the Association. President Huntley, of the Association, has been active in arranging for the present convention, and to him is due very largely the credit of having made it a working convention. The Papers promised are of considerable interest and importance.

Long Distance Transmission.—At the meeting of the American Institute of Electrical Engineers last Tuesday night, an interesting Paper was read by Lieut. F. Jarvis Patten, on some conversion systems of his designing, by which the same machine could be made to give either direct, alternating, or three-phase currents in various combinations. The Paper provoked a good deal of discussion on the long-distance transmission of power, in which many interesting facts were brought out. Particularly noticeable was the belief on the part of some of the prominent members of the Institute, in the practicability of long distance transmission by continuous currents. The feeling with regard to the "Drehstrom" system appeared to be decidedly conservative.

CORRESPONDENCE.

THE MAGNETIC PROPERTIES OF OXYGEN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your number of February 19th you comment on an article by M. Guillaume in *L'Industrie Electrique* in which it is stated that oxygen possesses, in a field of medium strength, a magnetic moment per gramme twice that of iron; so that the strange conclusion would be forced upon us that oxygen is the most magnetic of substances. Now, I found (*Wied. Ann.*, Vol. XXXV., p. 163, 1888) the susceptibility of oxygen (1 atmo.,

Digitized by Google

15°) to be $+\cdot117 \times 10^{-6}$, in good agreement with Faraday's and Becquerel's estimates. The density being ·00135, this gives a "specific susceptibility" of practically one ten-thousandth, which may just be reached with saturated alcoholic solutions of ferric chloride; such a liquid, again, could be made to rise 10cm. above its own level in a field of something like 20,000 C.-G.-S., and would doubtlessly fly at the poles if left free to do so.-

On the other hand, twice the maximum "specific magnetisation" of iron amounts to 500; for magnetite I have shown that quantity (taken singly) to be 70 C.-G.-S. per gramme. Even to reach the latter oxygen would therefore require a field of 700,000 C.-G.-S., rather over "medium strength." As no experimenter until now has reached over 30,000 (in air) nor is anybody likely to get much further, the ferro-magnetic family need hardly fear the competition of the new intruder.

None the less, a numerical determination of the susceptibility of liquid oxygen, say at boiling temperature, would be highly valuable, though probably still more difficult than causing it to splash about magnet poles, which is quite interesting enough in itself.—I am, Sir, &c., H. E. J. G. du Bois.

Physical Institute, The University, Berlin,
February 23, 1892.

Monsieur: J'ai l'honneur de vous envoyer la lettre ci-dessus, que M. du Bois a bien voulu me communiquer, pour le principe *et auditur altera pars*; je m'empresse d'ajouter que je reconnais tout le bien-fondé de son observation, la conclusion étrange à laquelle j'étais arrivé ne reposant que sur une impardonnable erreur.

Veuillez agréer, Monsieur, l'assurance de ma considération très-distinguée.

Ch. Ed. Guillaume.

ELECTRIC LIGHT CABLES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: We have recently heard electric light cables discussed at some length, but I venture to think somewhat superficially.

There seems to me to be about as much reason for an engineer to base the breaking strain of steel on that of glass as for Mr. Preece to base the breaking strain or point of disruptive discharge of india-rubber or any other insulator on that of air.

Some of the speakers at the discussion of Mr. Preece's Paper considered it best for electrical engineers to leave the subject of electric light cables entirely in the hands of the manufacturer. For the consolation of these gentlemen I may mention that within the last few weeks I have examined samples of rubber cable made by a well-known manufacturer, and find that the pure rubber adheres neither to the wire nor to the compound rubber. The latter very much reminded me of the inferior white rubber from which cheap garden hoses are made; it was utterly devoid of elasticity, breaking short in two when stretched between the fingers; and I have no hesitation in saying that over 80 per cent. of that compound was French chalk or zinc oxide.

I am quite aware manufacturers cannot afford to give you a good rubber cable unless they are paid for it; but on reading the specification and observing the prices of these cables you do not feel inclined to place implicit faith in the manufacturer of electric light cables more than in any other manufacturer. When purchasing rubber rings or pipes, or indeed any articles made from this substance which will be subjected to a varying stress, if we wish them to be durable, we well know they must be highly elastic. Now, whether this stress is caused mechanically or electrically is immaterial; what we then require is a rubber of high elasticity, *i.e.*, of great purity.

The following are, I consider, the chief conditions to be fulfilled by a good rubber cable:—

1. The rubber must be highly elastic; this applies to both the pure and the compound rubber, although, of course, not equally.

2. The electrification of the cable under test must be great, and should at least be 35 per cent. between the first and second minutes.

3. The specific resistance should be high.

Mr. Preece tells us he does not like a rubber with too high a specific resistance; but I think all manufacturers will agree with me when I say that pure rubber should have a high specific resistance, the compound rubber depends on what is mixed with it.

It has been clearly proved that gutta-percha cable should not have a high specific resistance, and not more than 5 or 6 per cent. electrification between the first and second minutes, as both a high specific resistance and a large electrification almost invariably indicate the presence of resin; but it is most unfair to reason in the same way about rubber cable, which is a totally different article. With regard to the testing apparatus or semi-cure for rubber shown to us by Mr. Preece, in many ways it is most excellent; but whether the specimen passes this test or fails must depend to a great extent how much the rubber has been previously cured.

Great care should be taken by electrical engineers in selecting the rubber they propose to use for jointing, as these are very often the weak points in a system of mains; such rubber should be highly elastic and adhesive, to test this latter quality two pieces of the pure strip should be selected, and the two ends placed on an iron block so as to overlap one another, and then struck smartly with a hammer, when they should have firmly united. I think, Sir, you will agree with me, that since the electrical engineer now spends such a large sum of money on rubber cables, it behoves him to examine them carefully for himself, and not to take for granted all the manufacturer tells him.—Yours, &c., J. Leslie Fuller.

Hampden Club, Phœnix-street, N.W.

POWER MEASUREMENT.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have seen a report that, in a recent number of the *Atti della Regia Accademia delle Scienze di Torino*, Prof. Galileo Ferraris is credited with a statement which might mean that one of the formulæ which appear in a Paper read by me before the Physical Society of London in May, 1888, was derived from a Paper by him. If that be Signor Ferraris' meaning he is entirely mistaken. My formulæ were obtained quite independently of Signor Ferraris or of anyone else.—Yours, &c.,

Thomas H. Blakesley.

Royal Naval College, February 29, 1892.

ELECTROLYSIS OF COMMON SALT.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I find it generally not known in London and the South that the electrical decomposition of salt has for a long time engaged the attention of leading alkali manufacturers in Widnes and other places northwards; and there is evidence, from conversations I have had the opportunity of having with several electrical engineers and others in the South, that a good deal of misconception exists as to what constitutes practical alkali manufacture.

Some electrolytic processes for dealing with salt have recently appeared, and are appearing, in London; and at the conclusion of a recent notice of one erected at Battersea you wind up by saying, "Whatever the upshot of the present attempt may be, it has at least been made on a fair scale." . . . .

But I must ask, Sir, in what respect is the apparatus described to be considered as having been tried on a fair scale? If it is meant, as I believe it is, that the apparatus for electrical measurements is tried on a fair scale, then the value of your opinion in this respect is properly defined. By some people, ignorant of chemical manufactures, it may be taken to mean that the process for manufacturing caustic soda and bleach commercially was tried on a fair scale. This meaning, however, it cannot be made to convey, because you previously state a weak point in regard to the rate of production in relation to the bulky and expensive plant.

My excuse, therefore, for troubling you is to remove any probability of your opinion being wrongly construed, as obviously it is not meant to imply, as some of my non-chemical friends have considered it does, that the electrolysis of common salt has yet been proved successful on a commercial scale of manufacture. In the North we do not consider any alkali process properly tried commercially unless the plant be capable of turning out at least five to ten tons a week.—Yours, &c.,

Dundee, March 1, 1892. Northerner.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—The Corporation of Walsall invite tenders for constructing, supplying, and laying down the necessary plant, machinery, and apparatus for lighting part of the borough by electricity. Further particulars will be found in our advertisement columns, and full information can be obtained on payment of £1 (which will be returned on receipt of a *bonâ fide* tender) to Mr. John R. Cooper, town clerk, Borough Offices, Walsall. Tenders must be sent in before Saturday, April 9th.

——— The Glasgow Corporation invite tenders for (1) the mason work and excavation, &c., works, and (2) the iron work, required in the construction of a central electric lighting station at the corner of Waterloo-street and Mains-street. Plans and specification may be seen and forms of schedule obtained on application at the Gas Office, 45, John-street; and tenders, addressed to the Committee of the Town Council on Gas Supply and Electric Lighting, must be lodged with Sir J. D. Marwick, Town Clerk, City Chambers, on or before Tuesday next.

——— The civil authorities of the town of Louvain are asking for tenders, by May 1 next, for the electric lighting of the Rue de la Station, the Place de la Station, the Grande Place, and the Theatre.—— Tenders are also being invited for the electric lighting of the military establishment at Briançon, France.

——— The Director-General of Communications in Spain is inviting tenders for 85 tons (metrical) of copper wire, 3mm. diameter, and 20,000 insulators. Tenders should reach the office of the Director of Communications, Calle de Carretas 10, Madrid, by the 14th inst.

THE E.C.C. DRY CELL.—The Electrical Power Storage Company (Limited) announce that they have appointed the General Electric Company (Limited) the sole licensees for the sale of this cell, which is being largely used on account of its suitability for telephonic and other electrical purposes.

THE SUNBEAM LAMP.—The following notice is issued to their customers by the Sunbeam Lamp Company:—"We much regret to have to inform you, that owing to action taken by the Edison and Swan Company, we shall be unable, during the continuance of the Edison patent, to meet any more of your valued orders for Sunbeam lamps. We have consented, rather than enter into a costly litigation with the Edison and Swan Company, and in view of the early expiry of both their patents, to suspend their manufacture."

MESSRS. MAVOR AND COULSON.—This firm announce that the sale to the Glasgow Corporation of the electric supply stations does not in any way affect their general business of manufacturing and contracting electrical engineers, which will be carried on as hitherto.

THE BOY MESSENGERS AND ELECTRICAL CALL COMPANY (LIMITED) notify their subscribers that, owing to the action of the Post Office in enforcing the payment of a tax of one penny on every letter carried by the Boy Messengers, they are compelled to make this additional charge of one penny on all letters so carried, the alteration to come into effect on March 7th. All messages, &c., not subject to the Post Office tax will, of course, be carried at the old tariff.

MESSRS. TRACKSON BROTHERS.—This firm write us from Brisbane that they have recently installed the electric light in the far West at Thargomindah, where kerosine frequently commands from 50s. to 60s. per case, and coal £12 per ton. Thargomindah can boast of being the first town in Queensland that has adopted the electric light. "Firth" dynamos of the latest type have been used, for which 96 per cent. efficiency is claimed. The machines have been built with special reference to the heat prevailing in the district where the installation has been made. Incandescent lamps, ranging from 16 to 500 c.p., have been used. A Robey engine has also been supplied for the plant, which will be used in the daytime for pumping, driving fans, &c. We understand that Messrs. Trackson Bros. have other similar contracts in hand.

THE P. AND O. STEAMER "HIMALAYA."—The electric light on this new steamer, launched at Greenock on Saturday, is supplied by Messrs. Siemens Brothers (Limited), and the electric bells have been fitted by Mr. C. E. Zimdars.

PRIESTMAN OIL ENGINE.—Messrs. Priestman Brothers are issuing a reprint of an interesting article on their oil engines, by Prof. W. Robinson, from the *Engineer*, with some additional illustrations, showing the various uses to which their engines are now being regularly adapted.

TRADE MARKS IN JAPAN.—Mr. A. C. Bickley writes to the papers that the Japanese authorities inform the society of which Mr. Bickley is general manager, that so long as British subjects in Japan require their cases tried in the Consular Courts so long will the Japanese Government refuse to allow protection to British patents, trade marks, or designs. Forgery of these trade marks and designs is very common in Japan, and Mr. Bickley states that they are the cause of enormous injury to British trading interests.

THE ELECTRIC APPARATUS COMPANY.—The dividends in the liquidation of this Company have now, we understand, been paid, and the Company is to be shortly dissolved.

ATLAS ELECTRIC APPLIANCES COMPANY, LIMITED (IN LIQUIDATION).—A meeting is to be held at the liquidator's on April 1st, at 3 p.m., to receive a report of the winding up.

BRITISH MEKARSKI IMPROVED AIR ENGINE COMPANY, LIMITED (IN LIQUIDATION).—A meeting is to be held at Mr. C. D. Woolley's, 1, Great Winchester-street, E.C., on April 7th, at 2:30 p.m., to receive an account of the winding-up.

FISCHER ELECTRO AMALGAMATOR COMPANY, LIMITED (IN LIQUIDATION).—A meeting will be held at Messrs. Ford, Rhodes, and Ford's, 23, College-hill, Cannon-street, E.C., on April 5th, at 12, to receive a report as to winding up.

PRETORIA.—A successful installation of the electric light was made recently at Pretoria by Mr. Van Zwieten, the local agent for Messrs. Woodhouse and Rawson United (Limited), on the occasion of a Horticultural Show.

COMPANIES' MEETINGS & REPORTS.

Electric Construction Corporation (Limited).

A general meeting of the holders of the founders' shares of the above-named Company was held at Worcester House, Walbrook, yesterday, for the purpose of considering, and, if thought fit, passing the following resolutions:—

"1. *That the capital of the Company be increased to £750,000 by the creation of 25,000 new shares of £10 each, numbered 50,001 to 75,000 inclusive.*

"2. *That the whole or any part of the said 25,000 new shares of the Company may be issued with any such rights of preference over the founders' shares, whether in respect of dividend (not exceeding a cumulative preferential dividend at the rate of 7 per cent. per annum upon the amounts credited as paid thereon), or in respect of repayment of capital or both, and with such right of voting, and generally upon such terms and conditions in all respects as the Company may from time to time by special resolution determine.*

The notice calling the meeting stated—

"I am happy to inform you that, owing to large and valuable contracts and orders obtained since the last general meeting and in immediate prospect, the Directors consider the time has arrived when additional capital can be employed to great advantage in extending the business of the Corporation, and materially increasing its profits."

Mr. SPENCER BALFOUR, M.P., presided.

Mr. W. SAMSON (the Secretary) read the notice calling the meeting.

The CHAIRMAN: Gentlemen: You are aware of the circumstances and conditions of this meeting. It is not a general meeting of the shareholders of the Company—that is to be held a little later; but this meeting is a meeting of founders' shareholders—holders of founders' shares; and under the terms of the Memorandum and Articles of Association they have to be consulted in any step that we propose to take in the increase of the capital of the Company. The reasons for that increase are stated in the circular which has been sent round to our shareholders; and I am glad to say that since our last general meeting—which I think we shall all agree was of a satisfactory character—and since the publication of the report and accounts—which also I think you will concur with me were of a satisfactory character—the business of the Company has very very largely increased indeed. There is, without wishing to say anything in terms of exaggeration, something like a "spurt" or "boom" in the way of orders for very heavy electrical plant. Now, as I stated, gentlemen, at the last meeting, the capital of the Company is already fully employed; and I am informed by Mr. Parker, our very able and successful works manager, that at the present moment we have in hand work at the actual moment equal to at least half of the whole of last year's work. We have that in hand at the present moment ——

Mr. PARKER (interrupting): Mr. Chairman, I think that is hardly a sufficient statement; if you will allow me to correct you. The orders we have in hand to-day, and what we have already delivered this year, are more than twice what we did in the whole of last year.

The CHAIRMAN, continuing, said: I am very glad to hear that. My business is not to exaggerate, but rather to under-estimate our prospects; and I am very glad indeed to have that correction from Mr. Parker; but taking it at that modest statement that I have put forward, our work in hand to-day equals the whole of the work which we had in hand in the six months of last year. You will see, therefore, that additional capital can be employed to very great advantage; and we therefore propose to ask the founders—I shall confine myself to the founders' point of view at this meeting—we shall ask the founders to concur in a resolution authorizing the additional capital. This is strictly within the terms of the original prospectus. In the prospectus issued we stated that as the business of the Company increased so we should come to the shareholders for additional capital. Well, the business of the Company has increased and is increasing; and in

Digitized by Google

addition to the large orders that we have in hand, and in addition to what Mr. Parker has said, we have before us at the present moment very large and very paying orders, involving, of course, a considerable outlay in the first instance in wages and for machinery; but yielding, as we believe they will, very large and very considerable profits to the Company. I am sure that I am speaking the unanimous opinion of the Board when I say that never since the Company has been established were its prospects anything like so flourishing or so promising as they are to-day. We all take heart at the present condition of the Company, and we believe that the founders themselves will be largely benefited—I am speaking to the founders now, and not to the ordinary shareholders. We believe that the founders themselves will be largely benefited by this increase of capital, because if, as is probable, we shall issue a portion of these shares at a fixed preferential rate below the rate at which the ordinary shareholders will be entitled to participate in dividend, prior to the founders. that must be to the advantage of the founders. I am a holder myself of founders' shares—no less than five founders' shares—and the Board also are large holders of founders' shares. We have had several questions asked us, and the explanations which we have given have been deemed satisfactory, and I trust we shall have the unanimous approval of the founders of this step. If so, and the promises we now have before us are fulfilled—which I have every reason to believe they will be—then the founders' shares in this Company will prove a very valuable investment indeed. I beg to move the resolutions of which you have had notice. I may, however, here anticipate a question which may be put hereafter as to how we propose to raise this additional capital. Of course, we do not propose to issue the £250,000 of additional capital at once. That is not in contemplation, but it is not worth while to incur the expense of continually holding meetings for the purpose of raising additional capital. We propose to get powers to go up to £250,000 new shares, but probably we shall be content with considerably less than that. In the first instance I look to an issue of about £50,000, or, at the outside, £100,000, which is quite sufficient for our purposes at present. Then, when we have proved the success of these orders, and brought the Company into a still more prosperous condition than it is to-day, then we shall probably raise the remainder, perhaps some of it as ordinary shares, and give the founders and ordinary shareholders the right to take it up at par, or in any other way as may seem fit to the shareholders. In the first instance we shall take powers to raise the £250,000, but we have no idea whatever of certainly exceeding the £100,000.

Sir DANIEL COOPER seconded the motion, and said he, too, was a holder of founders' shares—five founders' shares—and he was also a considerable shareholder in ordinary shares, and he would not support the proposal unless he was firmly convinced that it was necessary for the Company to get additional capital if they wished to be in a successful state—that was to say, the state that they anticipated when they formed the Company; and unless they got some extra capital in the way they asked now, then the business would not thrive in the way that it ought to thrive. He hoped that the founders would unanimously consent to this resolution.

The CHAIRMAN invited discussion.

No questions were asked.

The CHAIRMAN then put the resolution to the meeting, and it was carried unanimously.

The CHAIRMAN: I am sure, gentlemen, the founders have taken a very wise step in respect to their own interests. It is necessary that the resolutions should be signed by three-fourths of those present, so the solicitor states, in conformity with the articles.

The shareholders then signed the resolution, and the proceedings closed with a vote of thanks to the Chairman.

An extraordinary general meeting of the shareholders of this Company was held at Worcester House, Walbrook, immediately after the founders' shareholders meeting, for the purpose of considering and, if thought fit, passing the following resolution as a special resolution:—

"*That the capital of the Company be increased to £750,000 by the creation of 25,000 new shares of £10 each, numbered 50,001 to 75,000 inclusive.*"

Mr. SPENCER BALFOUR, M.P., again presided.

The Secretary (Mr. W. Samson) read the notice calling the meeting.

The CHAIRMAN: Gentlemen, you have heard the notice convening the meeting read, and I will now move the resolution. The reasons for the proposal, I believe, have been expressed to you in the circular which was issued at the same time that this notice was sent out, announcing to you its objects. And to that circular I have only a few words to add. The proposed increase of capital is entirely the result of the increased progress and prosperity of the Corporation, which, I am happy to say, to-day is in a sounder and stronger position as regards its finances and as regards its orders than it has been since its establishment. The people who will probably be most affected by the increase of capital will be doubtless the founders—the holders of the founders' shares; and I am pleased to be able to tell you that at the extraordinary meeting of the founders' shareholders held to-day a resolution agreeing to the increase of capital was passed by them unanimously. I ought to mention, gentlemen, that being anxious to be able to justify, in every sense of the term, the proposal of the Board, I communicated with the manager—the very able and very successful works manager of the Corporation—Mr. Parker, because I desired to be able to state accurately to you, on his authority, the exact position of the orders which we are receiving to-day. As I said at the founders' meeting, so I can say here. There seems to be something, if not a "boom," at all events a considerable "spurt" in electrical business at the present moment. Our works—our very large and new works at Wolverhampton, which are stated to be the best works of the kind in the country—which last year were by no means in full work—are at the present moment working as hard as possible and are fully occupied; and the work which we are doing and have done during the past five months of the present financial year, on orders in course of execution or actually executed, are fully one and a-half times the total orders that we turned out last year. That is to say, in the first five months of this year the work executed and in hand amounted to something like £180,000.

Mr. PARKER: £187,000.

The CHAIRMAN: £187,000, against about £130,000 for the whole of last year. Well, such an expansion as that in the business of the Company you will all know, as men of business, necessitates an increase of the capital of the Corporation, because we of course are some weeks, and in some cases some months, out of our money—wages have to be paid regularly every week; large orders have to be given for materials, and the greater we increase our capacity for paying cash and dealing promptly with these orders the better and larger are the profits we are able to make for the Corporation. I do not know, gentlemen, that I need occupy your time longer than possible on the further increase of capital, I will only go on to mention that this has been in contemplation—it has not been "sprung" upon you. It was contemplated in the original prospectus that a much larger capital would be required, and the Directors pledged themselves that as the work proceeded so they would offer additional capital—they would propose to issue additional capital, and offer it in the first instance (as we shall do certainly)—to the existing shareholders. Now, as regards the additional capital the Board are not yet committed to any plan for raising it, and it is not in contemplation, for one thing, that we should raise the whole £250,000 directly. We propose to take powers to go up to that amount. No one suggests for one moment that we want the whole £250,000. At the present moment £50,000 or £60,000 could be employed to very great advantage. The rest would be employed later on as we make further progress. The mode of the issue of the capital the Board have not yet determined upon. The first step is to get authority to increase the capital; but no step will be taken as to the mode in which the capital is to be raised without calling the shareholders together to get their consent to the mode proposed by special resolution. The Board are very anxious to take the shareholders into their confidence, to walk side by side with you, and to have your full support and concurrence in any step which must be taken. We are advised that the first course is to get the power to increase the capital; and as to the mode in which that capital is to be issued, we shall call the shareholders together and get their consent as to what is required. I do not think I need trouble you any more. I shall be very glad to answer any questions that may be put to me. I may add, however, in addition to these very large orders I have mentioned, and this enormous increase of business—profitable business—that we are doing to-day, we have in view two or three very big orders indeed; bigger indeed than any orders we have yet undertaken. So the prospects of the Corporation could not, I think, be more favourable, and it would be a crying shame if we were to lose this opportunity of securing this business because we have not sufficient loose working capital at our disposal. We have nothing to hide, nothing to conceal in the matter, everything is straightforward and aboveboard, and I can assure you, gentlemen, that I honestly believe, as a large shareholder myself, it will be to the advantage of us all to get the additional working capital. I move the resolution.

Mr. J. IRVING COURTENAY (Vice-Chairman) seconded the motion.

Dr. DRYSDALE: Might we ask as to whether you have any idea as to the way this capital will be issued?

The CHAIRMAN: I do not quite understand your question.

Dr. DRYSDALE: What is the proposition?

Another SHAREHOLDER: Is it to be in the way of ordinary or preference shares?

The CHAIRMAN: I have already stated that the one proposition before this meeting is the formal and merely legal proposition to increase the capital of the Corporation. As to whether this increase should be by way of preference or ordinary shares, and as to how much shall be paid up, that is entirely a matter for the future. The Board have not committed themselves to any view on the subject at the present time. They will come before you with a proposal at another meeting, and take you into their confidence as to the best mode of dealing with the matter.

Dr. DRYSDALE said he would like a more definite answer, if he could get it.

The CHAIRMAN: I should be very glad to tell you if I could, but I think it much better that in this matter the Board should move tentatively. One of the largest shareholders has proposed, and has strongly urged upon us to issue the whole of the additional capital, and to call it up over a period of several years, offering it *pari passu* to all the shareholders. Another mode is that we shall make smaller issues as the business requires: that is another matter. We shall consider every method on its own merits, and we shall recommend to the shareholders what ultimately we deem best to the advantage of the Corporation. You shall certainly have an opportunity of expressing your opinion as to our method before we adopt it.

The resolution was then put and unanimously carried.

The CHAIRMAN: I think, gentlemen, I may assure you that the Board may be looked upon to do what is right in this matter.

Mr. W. J. CARRUTHERS-WAIN: I think, Mr. Chairman, you have used the word confidence, and it is because we have confidence in the personal ability and commercial knowledge of the gentlemen of this Board that we have passed this resolution unanimously to-day. We have hopes that this confidence will be justified. The increase that the Chairman has given us of the business is very satisfactory, and the best thing I can hope is that the increase of business will lead to an increase of dividend. I propose a vote of thanks to the Chairman for presiding.

Dr. DRYSDALE seconded the motion, which was carried.

The CHAIRMAN briefly responded, and the proceedings terminated.

Telegraph Construction and Maintenance Company (Limited).

The twenty-eighth ordinary general meeting of the members of this Company was held at the offices, Old Broad-street, on Tuesday, under the presidency of Philip Rawson, Esq , J.P.

Mr. WILLIAM SHUTER read the notice convening the meeting, and the minutes of the last meeting.

The CHAIRMAN then said: Gentlemen, I am sure you will regret very much, as we all do, that our Chairman is unable to be present to-day. He has sent us a telegram from Egypt, where he is now on his way home, saying that he regrets exceedingly that he is not able to be present to-day to congratulate you on the report and accounts which we have now to lay before you. The duty therefore devolves upon me to move the adoption of the report and accounts; but I should first ask you whether you will take them as read. In moving this resolution, I am glad to tell you that I have not much to say, because the accounts show continued prosperity, and that we have done a fair amount of work during the past year, which leaves a very satisfactory result. You will notice that the accounts for the past year show a net profit of £85,199, after charging the interest on the debentures. To this sum comes to be added £61,524 brought forward from last year, making a total of £146,724, which we have to deal with. Of that amount the interim dividend which was paid in July last absorbed £22,410, leaving £124,314 now to deal with. Of this sum the Directors propose to distribute a dividend of £1. 16s. per share, which will take £67,230, being at the rate of 15 per cent., and making, with the amount already paid, a total dividend of 20 per cent. for the year, leaving £57,084 to be carried forward to the present year. If you refer to paragraph 4 of the report you will notice that the work carried out during the year has been considerable, principally owing to the completion of contracts entered into during the year 1890—that is, the laying of the cable manufactured for the most part during the previous year. At the same time we have had some work in manufacturing new cable, and business also in connection with our Gutta-Percha Works—the home trade. I may say at once with regard to the general gutta-percha business of the Company that it is a pleasure to be able to say that it continues in a satisfactory and improving position. We mention with regret that we have lost the services of Sir Thomas Fairbairn, who for 21 years served on the Board. We have been fortunate in being able to again secure the services of a former Director of this Company in the person of Admiral Lord John Hay. He, as most of you know—perhaps all of you—having received a high official command, was obliged to resign his seat at the Board; but as a vacancy has now occurred through the lamented death of Sir Thomas Fairbairn, we were very glad to fill it by electing Lord John Hay, who is again free from service afloat. I do not think there is very much that I need occupy your time with in connection with the figures of the accounts, but I shall be very glad to answer any question which you may desire to put to me. The accounts are drawn up on the old lines, and those who have followed these figures from time to time will see that there has been no very great change. I may state, although I have already said it, that your Gutta-Percha Works are doing well and improving; and altogether the position of the Company is very satisfactory. We have a fair amount of work in hand, which will go to assist the profits of the present year, I hope. If any gentleman desires any information I shall be very happy to give it, as far as lies in my power. Meantime I move:—

"*That the report and accounts of the Directors to December 31, 1891, submitted to this meeting, be and the same are hereby received and adopted, and that a dividend of 30s. per share, in addition to the 12s. per share interest or interim dividend paid to June 30, 1891, be paid on all the shares of this Company for the year ended December 31, 1891, and that such dividend be paid free of income-tax.*"

Mr. GEORGE W. CAMPBELL: I have much pleasure in seconding that.

The CHAIRMAN: The dividend warrants will be forwarded by to-night's post.

Col. CATER asked why it was considered necessary to carry forward so large an amount as £57,000 to the next account. The Chairman had told them that the Company was in a very promising condition, and therefore he thought—and no doubt the shareholders would have the same feeling—that a substantial bonus might have been paid to them this time out of the £57,000; and they could still have carried forward a good balance to meet the next dividend, which would only amount to £22,410. The £57,000 this year, and the £61,000 last year, were very large amounts—unprecedented, he thought, in any Company—to carry forward. They far exceeded the reserve fund, which only amounted to £50,000. If it was necessary to have a large amount of money in hand, he did not see why it should not be added to the reserve fund if it was not paid to the shareholders from time to time by way of bonus. The reserve fund was, it was said, the backbone of every company, and it was not a large reserve fund that they had. Having touched on the reserve fund, he thought it would be very interesting to the shareholders if the securities in which this fund was invested were printed on the back of the report in detail, showing the interest accruing from these amounts at the end of the year, and most certainly the interest should be added to the reserve fund. They now had to swallow what was printed and given to them; but he hoped that the Directors would see their way clear, when they distributed the next dividend, to give them a bonus. Instead of dividing 12s. a share let the amount be £1. If the Directors did not like to increase the dividend, which was not always desirable, let them pay the shareholders a bonus. He was very happy indeed to hear so favourable a report, and he hoped that the Board would, therefore, be able to see their way to giving the shareholders a bonus in future, instead of carrying forward so much.

Mr. CROFT observed that he had been a shareholder for many years, and in rising now to say a few words he must not be taken to assent to what the last shareholder had said. He had been in the Company for 25 years, and he was quite contented—and he believed that the great majority of the shareholders would be contented—to leave the question of paying a bonus or putting the amount to the reserve fund in the hands of the Directors, feeling confident that they would in the future maintain the same ability and integrity which they had shown in the past in the management of the Company's affairs. He knew that it had been the policy of Mr. Rawson's predecessors in the chair—a policy which was, no doubt, found in experience to work well—to discourage any undue inquisitiveness on the part of shareholders with respect to the business of the Company. He was confident from his own experience that this had been the policy of the Directors, and he believed it to be a wise one. He was not going to ask them to depart from it in the slightest degree in the question he was about to ask. He saw that a statement was made in the House of Commons some weeks back as to the laying of a cable between the Bahamas and the mainland. He saw that this cable had been laid by—he supposed he might call it—a rival Company. He did not want the Directors to disclose any necessary secret; but he wished to ask them whether this Company had a chance of laying that cable, and whether it rested with the Directors or not to tender for the contract. He thought they would be able to answer this question without disclosing any secrets.

The CHAIRMAN: I will answer the gentleman who first spoke. I believe—although I do not know if I am quite correct—that by our Articles of Association we cannot have a reserve fund exceeding £50,000. We are tied in that matter by our Articles. I think that that answers your question in regard to that point.

Mr. SHUTER: That is the statutory reserve, the amount which we have the power of reserving for our general or other purposes.

The CHAIRMAN: The gentleman who followed Col. Cater has, I think, pretty fully answered the objection you have raised with respect to this very large sum which we carry over. If you compare this £57,000 with the sum carried forward last year, there is a diminution of a few thousand pounds; but it is necessary that this Company, if they are to take large contracts, should be in as strong a position as possible, and it would be exceedingly bad policy if we were to divide our profits up to the hilt. It has always been the policy of this Company to keep as large a reserve as they could. I think in saying this I have answered your questions. With reference to the Bahamas cable, the contract was before this Company, but it was not such a one as we thought we could accept. If any other gentleman wishes to say anything I shall be happy to hear him, but if not I will put the resolution to the meeting.

No other shareholder rising to speak,

The CHAIRMAN put the motion in the usual way, and declared it carried unanimously. Continuing, he proposed that—

"*Mr. George William Campbell be and is hereby re-elected a Director of this Company.*"

Admiral Sir GEORGE H. RICHARDS seconded the motion, which was carried unanimously.

Mr. GIBSON next proposed the re-election of Mr. John Gane, F.C.A., and Mr. Patrick A. Glegg, as auditors of the Company for the year 1892, at the usual remuneration. He trusted that the duties of these gentlemen might always be as agreeable as they had hitherto been.

Mr. CROFT seconded the motion, which was adopted.

The CHAIRMAN having intimated that that terminated the business,

Mr. CROFT said he thought that before separating the shareholders ought to pass a vote of thanks to the Chairman and the Directors for the very able way in which they had conducted the business of the Company. Considering the financial troubles which the City of London had gone through in the last 18 months it was a very great feather in the cap of the Directors that they had been able to maintain the rate of dividend which had now been continued for a great many years.

Mr. GIBSON expressed his gratification at seconding the resolution, but said he wished to include the officers in the vote. He only hoped that they would always meet under as favourable circumstances as they did at the present time. However inclined they might be to receive a higher dividend, he felt sure that they would be very sorry to see any reverse take place in the position of the Company, and the prudent lines which the Directors took seemed the best guarantee against such a contingency.

The motion was carried unanimously.

The CHAIRMAN: On behalf of the Directors and also the officers, I thank you sincerely for the very kind way in which you have spoken of our exertions and the success which they have led to; and I can assure you that nothing shall be wanting on our part to secure an equal measure of success in the future.

The meeting then separated.

City of Bath Electric Lighting and Engineering Company (Limited).

The first annual meeting of the shareholders in this Company was held at the works, Dorchester-street, Bath, on Saturday, under the presidency of Lieut-Col. Vaughton, Chairman of the Board.

The report of the Directors was as follows:—

"The Directors have pleasure in submitting the first annual report and statement of accounts. The number of shares allotted is 3,246, upon which the sum of £31,981 has been paid. The result of the first year's operations of the Company is, in the opinion of the Directors, satisfactory. During the year the supply of current for incandescent lighting increased by 50 per cent., and the current is now supplied nightly to 102 arc lamps and 5,000 glow lamps. The gross profit amounts to £1,626. 8s. 5½d., and after deducting Directors' fees, salaries, and other standing charges, there remains a net balance of £585. 19s. 1½d. The Directors recommend that a

Digitized by Google

dividend at the rate of 4 per cent. per annum (absorbing £556. 16s.) be declared on the paid-up capital. The Directors have not written off any amount for depreciation, but all repairs and renewals have been charged to profit and loss account, and care has been taken to keep up all the plant to its original working efficiency. The engineer in chief, Mr. Olsson, reports: 'In accordance with your request, I have pleasure in informing you that the plant is in good working order. The engines and dynamos have been kept in thorough repair, and the mains, both for arc and incandescent lighting, are in perfect order.' The Directors propose, in order to meet future depreciation of machinery, and to provide for exceptional outlay in any one year, to constitute a renewals fund, to which the balance of revenue, after providing for the dividend above mentioned, will be carried. The electric light is finding increasing favour in the city, as is evidenced by the many fresh installations. Among other buildings, the Bath and County Club has been fitted throughout. Deputations from various towns have visited Bath during the past year, for the purpose of inspecting the company's works and lighting arrangements. The general testimony is that the central station is one of the most successful yet carried out, and the only improvement suggested by the deputations is that in some parts of the city additional arc lamps should be erected. The Directors anticipate that the coming year will show even better results, and they are giving special attention to the question of reducing the initial charge for installing the electric light. They are also considering the question of giving a day and night supply of electricity."

In moving the adoption of the report and statement of accounts, the CHAIRMAN said the Directors trusted that both would be satisfactory to the proprietors. There had been a very considerable increase in customers for the incandescent lighting, and since that report had been drawn up several new contracts had been entered into. At present the plant was up to double the amount of the work now required, and of course they would be very glad when even more customers would require supplies. The day and night supply had been under the consideration of the Board, but this would involve a considerable expense, and as yet it had not been settled when the matter would be carried out. It was also their intention to introduce meters in the course of the year. This would prevent any waste of current, and would place all customers upon an equal footing. By looking at the profit and loss account, they would see that the working expenses had been £4,318, while there still remained unpaid a balance of the purchase money of the undertaking amounting to £1,834. The Council had appointed Mr. Gatehouse as their inspector, and the Company would be only too glad to give him all the assistance in their power. They were able, happily, to speak very highly of their chief electrician (Mr. Olsson) and the other members of the staff. During the year they had received visits by delegates from other towns in the north of England. Their general testimony was that the installation at the central station had been most successfully carried out, and the only improvement they suggested was that in some parts of the town additional arc lamps should be erected. That, of course, rested with the city authorities.

Major-General JERVOIS seconded. He thought what they had heard from their Chairman was very satisfactory upon the whole. They knew that in the formation of a new company little difficulties were certain to arise. They had not been exempt from such, but he thought that so far they had very successfully overcome them, and he believed that soon they would receive that encouragement which they deserved. The Company promised in the future to be a great success; and he was of opinion that the citizens had every reason to be satisfied with the installation.

The report having been adopted, the auditor was re-appointed, and the meeting closed with a vote of thanks to the Chairman.

Northampton Electric Light and Power Company (Limited).

A general meeting of this Company was held at the Guildhall, Northampton, on February 25th. Mr. S. L. Seckham (Chairman of Directors) presided. The report stated that the mains already laid amounted to 2,800 yards, and that there were in use or being installed no less than 3,400 lights of eight candle-power. This, as Alderman Randall explained, was 1,400 lights in excess of anticipation. In consequence of the large increase in the business, it had become imperatively necessary to enlarge the machinery at an early date. The year's trading showed a loss of £461. 7s. 2d.; but that, it was explained, was owing to the expenses of a year's working being set against an income of only about three months. Mr. Cleaver and Mr. W. Tomes were re-elected Directors, and Mr. Hull was re-appointed auditor. Several Directors and shareholders spoke most highly of the prospects of the society.

Keswick Electric Light Company (Limited).

The annual report of the Directors of this Company states that during the past year they have experienced great difficulties in having to run the station with plant only partially supplied with water-power, in consequence of which considerable expenditure has been incurred in providing steam-power to supply the deficiency. The business of the Company continues to increase, and in order to meet the requirements it has been found necessary to make considerable extensions in the main wiring, the advantages of which to the Company are not yet fully felt. Notwithstanding these difficulties and the extraordinary working cost, the Directors have satisfaction in presenting a statement of accounts, which shows a balance upon the year's working of £87. 8s. 5d., which, being added to the balance left over from the previous year, leaves a sum of £122. 4s. They propose the payment of a dividend of £3 per cent., which will leave £44. 10s. 7d. to be carried forward to the next account. The receipts from consumers amount to £541. 11s. 2d.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of the majority of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, pages 308-322.]

JOHN ASTLEY AND SONS (LIMITED).—This Company was registered on the 26th February, 1892, with a capital of £3,000 in £5 shares, by Hooper and Son, 69, Ludgate-hill, London, E.C. The objects are to acquire, take over as a going concern, and carry on the business of, among other things, manufacturers of and dealers in electrical, chemical, photographic, and scientific apparatus and materials, carried on by the firm of John Astley and Sons, at 4, Broadgate, and Hales-street, Coventry.

"ELECTRICAL PLANT" (LIMITED).—The above-named Company was registered on February 27, 1892, with a capital of £10,000, in £10 shares, by Messrs. Crouch, Edwards, and Heron, 70, Basinghall-street, London, E.C. The objects are to acquire and take over as a going concern the business of the owners and proprietors of the monthly periodical known as *Electrical Plant*, now carried on at 52, Queen Victoria-street, in the City of London, by Henry Sherley Price and Wallis Rivers Goulty, and all or any of the assets and liabilities of the said owners and proprietors in connection with that business; and with a view thereto to adopt and carry into effect an agreement made between Henry Sherley Price and Wallis Rivers Goulty of the one part and the Company of the other part, to print, publish, and carry on the said periodical, either as a monthly periodical or otherwise, and either under its present or any other name; to establish, purchase, print, and publish any other newspaper, journal, magazine, periodical, or other publication in connection with the science of electricity; and generally to carry on the business of newspaper proprietors, printers, publishers, and advertising agents. The signatories to the Memorandum and Articles of Association are:—

	Shares.
Henry Sherley Price, 52, Queen Victoria-street, E.C., engineer	246
Wallis Rivers Goulty, Albert Chambers, Albert-square, Manchester, mechanical engineer	246
Ernest R. Dolby, 8, Princes-street, Westminster, consulting engineer	5
Sherley S. Price, jun., 52, Queen Victoria-street, E.C., engineer	1
Maurice Belsham, 52, Queen Victoria-street, E.C., engineer	1
W. Howard Goulty, 63, Brown-street, Manchester, solicitor	1
H. Cuthbert Hall, "Eversley," Elmfield-road, Bromley, Kent, electrical engineer	75

The number of Directors is not to be less than three nor more than seven, the first being H. S. Price, W. R. Goulty, and H. C. Hall.

"ESTON" ARC LAMP SYNDICATE (LIMITED).—This Company was registered on February 27, 1892, with a capital of £25,000, in £5 shares, by H. W. Christmas, solicitor, 42A, Bloomsbury-square, London, W.C. The objects are to carry on the business of an electric lighting company in all its branches, electricians, electrical and mechanical engineers, suppliers of electricity for the purposes of light, heat, motive power or otherwise, manufacturers of and dealers in all apparatus and things required for or capable of being used in connection with the generation, distribution, supply, accumulation and employment of electricity and any other business which may seem to be conveniently carried on by the Company; to purchase or otherwise acquire, develop, and turn to account any inventions, letters patent, &c., and in particular to acquire the patented invention for the arc lamp called the "Eston" arc lamp; and to construct, lay down, establish fix, carry out and supply all the necessary cables, wires, lines, accumulators, installations, lamps, and works for the generation, accumulation, distribution, and supply of electricity. Unless otherwise determined by a general meeting, the number of Directors is not to be less than three nor more than six, the first being W. Wynn Westcott, M.B., George North, M.I.M.E., A.M.I.E.E., Julius A. White, and Albert Essinger. The qualification of a Director (except first Directors), 20 shares.

HIND AND LUND (LIMITED).—This Company was registered on February 26, 1892, with a capital of £10,000 in £1 shares, by Hooper and Son, 69, Ludgate-hill, London, E.C. The objects are to acquire and take over as a going concern, and carry on in all its branches, the business of ironfounders, mechanical engineers, manufacturers of machinery of every kind, toolmakers, brassfounders, metal workers, electrical engineers, &c. now carried on at Preston, Lancashire, under the style or firm of Hind and Lund. Registered office: Edward-street, Preston.

PIONEER TELEPHONE COMPANY (LIMITED).—This Company was registered on February 26, 1892, with a capital of £100,000, in £10 shares, by Messrs. Dawes and Sons, Solicitors to the Company, 9, Angel-court, London, E.C. The objects are to procure the general establishment and development of telephonic means of communication and to diminish the cost thereof, and procure the adoption of improvements therein; to negotiate for and acquire provisionally or otherwise, lands, buildings, options, contracts, goodwills, patents, concessions, licences, easements, rights, claims, and business concerns and undertakings, and to promote the floating of a telephone company or companies, with ample capital and resources, and to make over to such company or companies all or any of the premises, patents, &c., so acquired, on such terms as may be arranged, and to assist and support any such company or companies; to carry on the business of a telephone company in all its branches, and to transmit and facilitate the transmission of messages and communications by telephone, telegraph, messengers, or otherwise; and to establish, manage, control and regulate telephonic exchanges and all kinds of conveniences and facilities which may seem likely to lead to the more general use of telephonic means of communication; to construct, carry out, maintain

Digitized by Google

improve, manage, work, control and superintend any cables, wires, lines, stations, exchanges, offices, electric works, factories, and warehouses, and to carry on the business of electrical engineers. Among the objects of the Company, not particularly alluded to in the Memorandum of Association, is included that of acquiring certain rights and interests secured to the Electric and General Investment Company (Limited) by an agreement dated January 1, 1892, under which the undertaking of the Mutual Telephone Company (Limited), in Manchester, may be acquired upon certain terms stated in the agreement. Another object is that of providing the necessary capital for the New Telephone Company (Limited), the objects of which are the acquisition, establishment, and working of telephonic exchanges throughout the United Kingdom, under licence from Her Majesty's Government, and for transferring to the said Company the rights and interests under the agreement of the 1st January, 1892, so to be acquired as above mentioned, and also certain provisional advantages in connection with "way-leaves" for telephone cables within the metropolis. The signatories to the Memorandum and Articles of Association are:—

	Shares.
Duke of Marlborough, 3, Carlton House-terrace	1
M. B. Praed, 189, Fleet-street, E.C., banker	1
J. B. Braithwaite, Jun., 18, Highbury New-park, N., stockbroker	1
F. W. Reynolds, Bromley, Kent, engineer and merchant	1
George Herring, 1, Hamilton-place, W.	1
Cecil Braithwaite, 10, Lyndhurst-Road, Hampstead, stockbroker	1
J. Cecil Bull, Broughton Lodge, Surbiton, Surrey, secretary to a public company	1

The number of Directors is not to be less than two nor more than ten, the first being the following:—The Duke of Marlborough, Colonel the Hon. Oliver Montagu, Charles Praed, and F. E. Savory. Registered office: 1 and 2 Great Winchester-street, London, E.C.

[Readers who desire more information respecting the New Telephone Company (Limited) and the Mutual Telephone Company (Limited) can refer to *The Electrician* of December 25, 1891, and to our last week's issue.]

THOMPSON, RITCHIE, AND CO. (LIMITED).—The above-named Company was registered on February 22, 1892, with a capital of £5,000, divided into 200 Five per cent. preference and 300 ordinary shares of £10 each, by Lake, Beaumont, and Lake, 10, Lincoln's Inn, London, W.C. The objects are to purchase or otherwise acquire and carry on and develop the business of electrical engineers, as now carried on by Arthur Stanley Grove at 34, Victoria-street, Westminster, London, S.W., under the style or firm of Thompson, Ritchie, and Co., and with a view thereto to enter into and carry into effect the agreement referred to in Clause 2 of the Company's Articles of Association (which is between Arthur S. Grove and the Company), and to carry on the business of electrical and general engineers, builders, decorators, iron and brass founders, carriage and waggon builders, &c. The signatories to the Memorandum and Articles of Association are:—

	Shares.
A. S. Grove, 34, Victoria-street, Westminster, S.W., electrical engineer	1 ord.

The number of Directors is not to be less than two nor more than four, the first being A. S. Grove and John C. Waltham. Qualification, 50 ordinary shares. Remuneration, £600 per annum, such amount to be divided as they themselves from time to time determine.

MISCELLANEOUS COMPANIES.—Amongst the companies recently registered whose objects have more or less connection with electricity are the following:—

Archibald Cousland & Co. (Limited); capital, £10,000.
A. Fearnhead & Co. (Limited); capital, £5,000.
British, Foreign, and Colonial Patents Syndicate (Limited); capital, £10,000.
Square Hole Boring Tools (Limited); capital, £25,000.
Oates and Green (Limited); capital, £50,000.

DURAND ELECTRIC, PETROLEUM, AND GAS ENGINE AND MANUFACTURING COMPANY (LIMITED).—In reply to letters addressed to this Company at 175, Strand, London, W.C., respecting its non-compliance with relation to the filing of returns according to statute, a letter has been received by the Registrar in which it is stated that the Company has never allotted any shares, had any shares subscribed for, or traded in any way, and should have been removed from the register. The Company was registered on March 15, 1890, with a capital of £100,000, in £5 shares, to acquire and carry on the business carried on at No. 163, Avenue Victor Hugo, at Paris, and elsewhere, by Eugene Durand, and to carry on the business of mechanical and electrical engineers, and manufacturers and dealers in electric, petroleum, gas, or other engines.

ELECTRIC TRAMWAYS CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—The annual return of the above-named Company, made up to the 13th February, 1891, was filed on February 8, 1892. The Company was registered on the 8th December, 1886, with a capital of £250,000, in £1 shares, to acquire licences to work or use any British or foreign patents or inventions capable of being used for the application of electricity as a motive power, particularly for the propulsion of tramcars or other vehicles, and to complete and carry out, with any variation or modification which the Directors might think fit, an agreement dated the 7th December, 1886 for the purchase and acquisition of certain letters patent granted to Michael Holroyd Smith, of Halifax, consulting and mechanical engineer, for "Improvements in tramways and railways, and the use of electricity as a motive power for tramcars." At the time of making up seven shares had been taken up, on which, however, no calls had been made, the original subscribers to the Memorandum and Articles of Association being the only shareholders. No agreements for the acquisition of any patents, inventions, contracts, plant, premises, &c., have as yet been filed. Registered office: Royal Insurance Buildings, Crossley-street, Halifax, Yorks.

SHEFFIELD TELEPHONE EXCHANGE AND ELECTRIC LIGHT COMPANY (LIMITED) (IN LIQUIDATION).—The following notice was filed with the other papers of the above-named Company on January 18, 1892:—"At a general meeting of the shareholders of the above-named Company, duly convened and held at the registered office of the Company, Station-road, Sheffield, on Thursday, January 14, 1892 (pursuant to Section 142 of the Companies' Acts, 1862), the following resolution was duly passed:—'That the statements of the liquidators and their report be and is hereby accepted and approved.' Dated this 14th day of January, 1892. (Signed) T. G. Shuttleworth, Wm. Johnson, liquidators." This Company was registered on September 11, 1888, with a capital of £60,000, in £10 shares, to purchase from John Tasker, of Sheffield, the goodwill of the following businesses:—The businesses of the Sheffield Telephone Exchange and the Rotherham Telephone Exchange, both in the county of York, established by the said John Tasker, and the plant, machinery, &c., used in connection with such businesses, including the licence of the Postmaster-General, to establish and carry on telephone exchanges, and to carry on the said businesses in all or any of their branches. On August 11, 1890, a notice was filed, stating that the liquidators of this Company had given their consent to the registration of a new company of the same name (which was registered on August 28, 1890, with a capital of £100,000, in £10 shares). Registered office: Station-road, Sheffield.

SIMPLEX ELECTRICAL SYNDICATE (LIMITED).—The following notice was filed with the papers of the above-named Company on February 17, 1892:—"To the Registrar of Joint Stock Companies. I have to inform you that a meeting of the Simplex Electrical Syndicate (Limited) was duly held on February 16, 1892, for the purpose of receiving an account showing the manner in which the winding up of the Company had been conducted, and the property of the Company disposed of, and that the same was done accordingly. (Signature) W. J. M. Menzies, Liquidator. Dated February 17, 1892." The above-named Company was registered on February 15, 1886, with a capital of £6,000 in £50 shares, to acquire, develop, and turn to account the following patents:—(*a*). No. 3,901, dated February 25, 1884, for improvements in electric arc lamps. (*b*). No. 15,030, dated November 14, 1885, for improvements in electric arc lamps. (*c*). No. 7,390, dated June 17, 1885, for improvements in arc lamps; and (*d*), No. 12,840, dated October 26, 1885, for improvements in secondary batteries.

CITY NOTES, &c.

ACTIEN-GESELLSCHAFT MIX AND GENEST (BERLIN).—The balance-sheet shows a gross profit on last year's working of 160,306 marks, and the Directors have declared a dividend of 6 per cent., and have written off 62,000 marks on plant and patents.

BOY MESSENGERS AND ELECTRIC CALL COMPANY (LIMITED).—A meeting of this Company was held on Tuesday at Anderton's Hotel, Fleet-street, E.C., but representatives of the press were not admitted.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended February 28th were £834, as against £754 in the corresponding period of last year, showing an increase of £80. The total receipts to date, from January 1st, 1892, are £7,061, against £6,233, an increase of £823.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of February were £3,600, as compared with £3,418 in the corresponding month of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of February amounted to £58,284, as against £59,155 in the corresponding period of last year, a decrease of £871.

EASTERN EXTENSION TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for the month of February amounted to £39,002, as against £43,833 in the corresponding period of last year, a decrease of £4,831.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—Major Flood Page was on Tuesday last elected a Director of the Company, to fill the vacancy caused by the death of Mr. Leyland. Major Flood Page was also elected Deputy-Chairman of the Company.

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—Mr. W. W. Duncan, in his report for March, again deals with the shares of this Company, in which he takes a very healthy interest. He strongly advises the purchase of Electric Construction shares generally and of the Electric Construction Corporation Shares in particular, in preference to Supply Companies' shares. He concludes by recommending the Directors to issue Seven per Cent. Preference shares, with a contingent profit after the ordinary shareholders had received a dividend of 10 per cent. He believes that there will be no difficulty in earning the dividends referred to. In reference to this issue of further capital we refer our readers to the report of the Corporation's meetings, held yesterday (Thursday), reported in this issue.

ELMORE'S FRENCH COPPER DEPOSITING COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee for 33,250 vendors' shares, Nos. 66,751 to 100,000, to be quoted in the Official List.

Digitized by Google

LIVERPOOL ELECTRIC SUPPLY COMPANY (LIMITED).—The Directors recommend a dividend for the year 1891 of 4½ per cent., comparing with 3½ per cent. for 1890.

PIONEER TELEPHONE COMPANY (LIMITED).—Subscriptions have been asked this week for £75,000, in 7,500 shares of £10 each, in the above Company. The prospectus was issued by the Electric and General Investment Company (Limited), and the subscriptions opened on Tuesday last and closed yesterday (Thursday) for London and this morning (Friday) at 11 a.m. for the country. The Company is ultimately to take over the Mutual Telephone Company (Limited) in Manchester, which will form the nucleus of the new telephone combination, which is called the New Telephone Company (Limited), which latter Company has been reconstructed for the purpose of entering into competition with the National and other telephone companies in London and the provinces. The prospectus states "*the profits of this Company will largely depend upon the successful issue of the capital of the proposed New Telephone Company*," whose Bill has yet to be considered by Parliament. The Directors of the Pioneer Company include the Duke of Marlborough; the secretary is Mr. J. Cecil Bull; and the offices, 1 and 2, Great Winchester-street, London, E.C. The authorised capital of the Company is £100,000, of which the present issue forms part.

SUBMARINE CABLES TRUST (LIMITED).—On and after the 15th inst. the coupon due in October last will be paid in full by Messrs. Glyn, Mills and Co. The coupons should be left with the bankers for examination four clear days before payment.

THE ELECTRICIAN:

A WEEKLY LLUSTRATED JOURNA OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 721.—Vol. XXVIII. FRIDAY, MARCH 11, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

A remarkable example of an invention, which was made several years too soon, is afforded by the oil insulation of Prof. Hughes. It was appreciated by very few people at the time, and practically adopted by none; it was put on one side by the inventor, who busied himself with other work; it was patented by another inventor fifteen years later; and now, after a period of thirty-three years, its value is becoming recognised. It might have found many useful applications within the fourteen years of the patent, but it is only with the introduction of high voltages that the real utility will be appreciated

Whatever the Electrical Exhibition at the Crystal Palace may have failed to do, it has certainly succeeded in fulfilling our anticipation that it would prove a great attraction to Town Councillors and others interested in municipal improvements. Hardly a day passes without a deputation being appointed to proceed to the metropolis with a view of making an expedition to Sydenham. These deputations, as a rule, originate somewhat as follows:—The Electricity Committee, completely befogged by conflicting expert evidence, suggests that it should be sent to see the wheels go round. The ratepayers' friend opposes the idea *in toto*. In the end the spirit of compromise prevails; the strength of the deputation is reduced by 50 per cent., and the ratepayers' friend is induced to go with it. A flying visit to an Exhibition does not, of course, enable a layman to decide an engineering question without any further ado; but it is to be borne in mind that the opponents of the electric light at Town Council meetings usually deny its existence in any other form than that of an expensive toy; an hour or two at the Crystal Palace is a powerful antidote to such a belief.

The very sudden alternations of light and darkness which have been experienced during the last few weeks in London have kept the attendants at electric supply stations unusually on the alert. Fogs and snowstorms have quickly drifted over the streets and have been spent or dispersed several times in a day, and the facility with which electric lights can be turned on and off has been thoroughly appreciated during this unusual weather. Lamplighters have been busily employed, but it seems to have been the duty of nobody in particular to order the arc lamps to be lighted in the City.

Mr. Shelford Bidwell exhibited at the Physical Society on December 12, 1890, and again at a *conversazione* of the Royal Society, some very ingenious applications of improved selenium cells. He told the meeting how he had arranged one of these, by a relay, to switch on an electric light when daylight failed, and how he forgot all about it until it duly operated at the end of the afternoon. With his usual modesty Mr. Bidwell put forward his various adaptations of selenium cells as mere suggestions, and had he patented them and pushed them commercially we should probably have heard something more about them. It is not only feasible, but it would be very easy and not expensive, to provide a number of these cells in different parts of a town for the purpose of signalling to a supply station that the light was failing, and, where public street lighting is used, to switch the lights on and off. The street lighting in the City is worked by separate circuits, and signal wires would have to be carried back to the station. But where street lighting is worked from the ordinary supply service with sub-stations, a selenium relay might be placed at each sub-station to turn on the street lamps of that district. One modification which would be necessary would be a device to prevent continual lighting and relighting at the critical point of darkness, and another perhaps to reduce such lighting and relightings to a reasonable number in an hour.

A selenium cell connected to a bell to warn an attendant could be erected at a trifling expense at picture galleries, libraries, the Law Courts and other public institutions. At present the lights are not turned on until they are badly wanted, and are often left on long after the darkness has passed.

The electrical cooking operations, which have attracted so many visitors to the stand of the General Electric Company at the Crystal Palace Exhibition, has proved to be so popular that a room has been specially fitted up in co-operation with Messrs. Crompton & Co. for demonstrating various domestic applications of electrical energy. The internal thermal gradient and emissivity of a flat iron and the energy in calories required for a single application of curling tongs are not to be found in any text book or pocket book; and the number of pounds of coffee which can be ground, knives which can be cleaned, or boots which can be blacked per Board of Trade unit, has never yet been published. To boil a pint of water

Digitized by Google

by electricity is easy enough. At a demonstration of the working of his electrical engine regulator about eleven years ago, Mr. Lane Fox provided electrically heated coffee for the visitors; and even at that time it was obvious that such an application of electric current offered the highest possible efficiency. There is no loss in friction, hysteresis, or polarisation; but the whole force of the great law that every form of kinetic energy always tends to degrade into heat, is used to boil the coffee.

Some figures relating to the relative expense of heating by electric current and by gas were given in *The Electrician*, January 15th, p. 271. We have examined the simple case of boiling a pint of water, and have neglected the losses, which may be very small, since the heat may be produced exactly at the point required. To boil a pint of water starting from 20°C. takes about 45,000 calories, and to do this in five minutes an expenditure of 625 watts, costing 0·42d. (at 8d. per unit), will be required. It must, however, be admitted that half a cubic foot of gas costing 0·018d. (at 3s. per 1,000) will do the same. The specific heat of a mutton chop is not given in the text books, it is probably not much above 0·5; but radiant heat is necessary, and the calculation of the energy required would be rather difficult. Mr. Tolver Preston has pointed out that the light and heat of the sun concentrated at the focus of a burning glass is nothing more than the heating of innumerable electro-magnetic fields. The mutton chop problem may perhaps therefore be handed over to Mr. Nikola Tesla.

Heilbronn.—The central station at Heilbronn, the first to be worked on the "drehstrom" system, is now running.

The Civil and Mechanical Engineers' Society.—The address of the above Society will in future be 12, Delahay-street, Westminster, S.W.

Lecture.—Mr. W. Perren-Maycock will lecture at Dulwich Scientific and Literary Association, on March 24th, at 8 p.m., on "Electricity and its Uses."

Prof. Elihu Thomson.—Prof. Elihu Thomson has presented the Académie des Sciences with the sum of money won by him in the Paris Municipality's electric meter competition.

The Bakerian Lecture.—Prof. James Thomson's Bakerian lecture on "The Grand Currents of Atmospheric Circulation" was read at the Royal Society yesterday, by the President.

Exeter.—Mr. H. G. Massingham has, by the request of the Directors and shareholders of the Exeter Electric Lighting Company, assumed, as lessee, sole control over the work of that Company.

"Leydic" Resistance.—E. Villari has been investigating the difference in the resistance offered by various metallic circuits to "the galvanic current" and to condenser discharges, and proposes to call the latter the *Leydic resistance*.

Liquid Oxygen Experiments.—At the general monthly meeting of the Royal Institution on Monday last the special thanks of the members were returned for the donations, amounting to £438, for carrying on investigations on liquid oxygen.

Electric Transmission of Power in Australia.—The Directors of the Mount Zechan Electric Power Transmission Company (Australia) intend to transmit power to the extent of 500 H.P. from the 5,000 H.P. available from the existing waterfalls of the Mount Zechan district.

Telephone Amalgamation.—The National Telephone Company have taken over the Caledonian Telephone Company under an arrangement by which the shareholders in the latter Company become shareholders in the National to the extent of their holdings in the Caledonian.

"The Electrical World."—In its issue of February 27th the *Electrical World* of New York announces the retirement of Dr. Louis Bell from the editorial chair, which he has occupied for some two years past. Mr. Carl Hering will in future be in charge of the technical department of the *Electrical World*.

Grosseto.—The town of Grosseto, Italy, has decided upon using electricity for both public and private lighting. Water power is available at a distance of two miles, and the transmission will be effected by alternating currents at 2,000 volts. Messrs. Siemens and Halske, who are providing the plant, have undertaken to have the lights running in three and a-half months.

Accumulator Litigation in Belgium.—The Société l'Electrique of Brussels, which owns the Faure patents for Belgium, having obtained the permission of the Brussels Court of First Instance, has attached all accumulators manufactured by the Société Franco-Belge pour la Fabrication de l'Accumulateur Tudor, and now threatens the Tudor company with an action for infringement and damages.

Cable Repairs :

	Date of interruption. 1891.		Date of repair. 1892.
Brest-St. Pierre Cable (Anglo-American)	Nov. 19 1892.	.. ..	Feb. 24
Zanzibar-Mombassa Cable	Jan. 25	.....	Feb. 23
Saigon-Bangkok Cable.....	Feb. 17	.....	March 1
Saigon-Singapore Cable	„ 18	.....	Feb. 25

Lighting of the Mansion House.—A private view of this installation took place on Monday evening. Some 800 lamps, ranging from 5 to 50 c.p. have been put up. The work has been carried out to the specification of Mr. W. H. Preece, and the wires have been run so that not more than ten lamps are placed upon one circuit. The work has been carried out by the Planet Electrical Engineering Company, and the current is supplied by the City of London Company.

The Phonopore.—A trial of the phonopore, says *Industries*, has recently been carried out between Lausanne and Villeneuve, on the Jura-Simplon Railway, with successful results, under the direction of the inspector of telegraphs of the Jura-Simplon Railway Company. The Railway Company is disposed to adopt the system on its lines, but owing to some disturbances on the telephone lines of Vevey and Montreux owing to induction, a difficulty has arisen with the State Telegraphs Department.

The Faure-Sellon-Volckmar Patents in France.—The *Bulletin International de l'Electricité* states that MM. Betts et Bellens, against whom the Société Française d'Accumulateurs Électriques recently commenced proceedings for infringement of the Faure-Sellon-Volckmar patents, have agreed to recognise the rights of the Société d'Accumulateurs, and to abstain from manufacturing secondary battery plates to which oxides and other lead salts are applied, except on payment of a royalty.

Copper.—During February the deliveries were 8,244 tons, against 5,587 tons during January. Once only during three years have the deliveries been so small as in January, 1892—namely, in March, 1889, when they were 4,399 tons. The supplies of the month were somewhat less than the deliveries—7,563 tons, compared with 7,005 tons in January. The stock in England and France and afloat there from Chili and Australia, was at the end of February 57,462 tons, as against 56,781 tons at the end of January.

The Proposed International Electrical Congress at Chicago.—It has been arranged by Mr. C. C. Bonney, President of "the World's Congress Auxiliary" of the Chicago Exhibition; Mr. O. Chanute, Chairman of the Engineering Congress Committee; and Mr. Elisha Gray, Chairman of the Electrical Congress Committee, that the section of the Engineering Congress relating to Electrical Engineering shall be merged into the proposed Electrical Congress. Due notice of this agreement from the office of "the World's Congress Auxiliary" will follow the recently distributed circular relating to the Engineering Congress.

University College, Liverpool.—Prof. Oliver Lodge intends shortly to fit up and furnish an iron building as an electro-technical laboratory for students in electrical engineering at University College, Liverpool. The committee of the County Council of Liverpool have made a grant for the purpose; and the staff proposed is a highly qualified demonstrator or assistant lecturer, a mechanic, and a boy. It will no doubt develop into a larger and more pretentious building as time goes on. For their mechanical engineering the students will be under Prof. Hele Shaw in the splendidly equipped Walker laboratories. Prof. Lodge hopes to have everything ready for work on October 1st.

Electric Lighting at St. Pancras.—The Chairman of the Electricity Committee of the St. Pancras Vestry, in a letter to *The Times*, says that an impression widely prevails that the Vestry of St. Pancras, having withdrawn their Parliamentary Bill, are tired of electric lighting, and have no intention of extending it in the parish. This is entirely a mistake. The first object of promoting the Bill was to raise money from the public, when a difficulty arose between the Vestry and the London County Council as to the period over which the repayment should extend. Since then the difficulty has been surmounted, and the necessary money has been borrowed. The present necessity for the Bill, therefore, has gone.

Hertz's Experiments.—R. Ritter suggests that in order to show Hertz's experiments before a large audience, a frog, prepared as for the Volta experiment, might be placed as a shunt on the secondary conductor. When the minute secondary sparks occur they are shown to the audience by the muscular contractions of the prepared frog. L. Boltzmann says that the same result can be obtained by placing one side of the spark gap in connection with a highly sensitive electroscope, and the other with one pole of a 200-volt battery (the other pole being to earth). The leaves of the electroscope diverge whenever a spark passes. E. Wichert substitutes a feebly-charged Leyden jar for the battery employed by Boltzmann.

Prof. Hertz on Electrical Propagation.—J. A. Barth, of Leipzig, will shortly publish a work, by Prof. Hertz, entitled "Untersuchungen über die Ausbreitung der elektrischen Kraft." The articles, in which Prof. Hertz, some four years back, first gave the world the result of his brilliant investigations, were published in the "Annalen der Physik und Chemie;" and as the several volumes of the "Annalen" cannot be obtained separately, Prof. Hertz's papers are now published in a collected form. The author has added an introductory preface pointing out the connection between the different articles. Since their first publication, many scientists have been at work in the same direction, and the investigations have been amplified and completed.

The Medical Utilisation of High Potential Alternate Currents.—In a recent communication to the Académie des Sciences, MM. G. Gautier and J. Larat describe some transforming apparatus employed by them to render the alternate current supplied by the Ferranti dynamos at the Halles Centrales (Paris) available for medical purposes. They give several reasons for hoping that an extended use of the alternate current will lead to beneficial results in many forms of disease. Even in the two and a-half months during which they have had their apparatus in working order, they have obtained extremely good results in certain cutaneous affections, such as eczema. With regard to the electrical production of ozone, MM. Gautier and Larat find that the ozone always contains nitrous compounds, and may, therefore, have injurious effects.

A Smoke Recorder.—At a recent meeting of the Manchester Section of the Society of Chemical Industry, Mr. W. Thomson described an instrument designed by him for recording the density of smoke passing in chimney flues. In a number of experiments Mr. Thomson found that by exposing pieces of paper in smoky chimneys and withdrawing them after a few seconds, he obtained dark marks corresponding in depth with the amount of smoke passing up. He also ascertained that it is essential, in order that the paper should be properly marked, that it should be kept cold. His apparatus therefore consists of an arrangement whereby a strip of paper is exposed for a definite time in the interior of a chimney, being changed by clockwork after a period of exposure, while it is kept cool all the time by water circulating through the tube on which it is wound. Comparative diagrams of the actual performance of a chimney at different times are said to be obtainable in this way.

The Kerr Magneto-Optic Phenomenon.—In studying the Kerr magneto-optic phenomenon H. E. J. G. du Bois employed long ellipsoids of revolution. Du Bois concludes from his experiments that the rotation must be considered as exactly proportional to the magnetic component normal to the mirror. The rotation is negative for iron, nickel, and cobalt, positive for magnetite. Temperature does not sensibly modify the rotation constants. In the case of nickel heated to a dull red, the rotation effect disappears at the same time as the magnetic susceptibility, reappearing with it. In Du Bois' opinion the Kerr phenomenon is exclusively attributable to penetration of the ray into the interior of the metal, since its magnetisation alone has any influence, the intensity of field not directly affecting the result. Du Bois suggests that the two inverse circular components perhaps penetrate to different depths, hence the dissimilarity between the Kerr phenomenon and the rotation produced by transmitting a ray *through* the substance.

Danish Telegraphs.—According to the report on the Danish Budget for the financial year 1892-3, which has just been laid before Parliament, it appears that no profit is obtained from posts and telegraphs; but, on the contrary, a loss is estimated of £8,650 in regard to posts, and of £11,588 to telegraphs. In the course of his remarks, the writer of the report, Mr. Conway Thornton, the second secretary to the Legation at Copenhagen, says:—"It is proposed to introduce a change of tariff for telegrams, it being found that the present low rate on the one hand encourages the sending of unnecessarily long messages, and on the other destroys the profit which might otherwise be obtained on the internal service. The rates now submitted are, for inland messages, 5 ore (rather more than ½d.) per word, with a minimum of 50 ore, and for press and City messages 2 ore per word, with a minimum in each case of 40 ore and 30 ore respectively." It is calculated that a total profit on the inland service will thus be obtained of £1,600 for the first year, and £3,200 for the succeeding ones.

The Electric Light in Tunnels.—Tunnel lighting by electricity seems to be coming into vogue abroad. For some years past the famous Hoosac Tunnel has been illuminated by incandescents placed at intervals. This tunnel, it may be interesting to mention, is between Albany and Boston. It was begun in 1851, and, after being twice abandoned, was finally completed in 1875. It is five miles long, and cost the State of Massachusetts about 3½ millions sterling. The tunnel of the New York Central Railway, running into New York, is, we believe, also to be lighted electrically; and at the present moment the French technical journals are publishing some curious details with regard to the electric light installation in the Batignolles Tunnel in Paris. Here two rows of incandescents (each now containing 150 lamps) are placed in each of the three tunnels, 16ft. above the rails. By means of parabolic reflectors and diverging lenses the rays are thrown on to the walls of the tunnel. To prevent absorption by the black walls tin sheet 6½ft. broad, enclosed in a glass frame, is fixed along the brickwork. It is proposed to make use of this part of the installation for advertising and similar purposes. The installation is expected to come into operation in April.

Coast Lights.—In a letter to last week's *National Observer* Prof. Tyndall writes as follows:—

"When the *Eider* disaster occurred, and when the powerful electric light at St. Catherine's Point had been reported ineffectual, I ventured to suggest the conversion of that steadily shining light into a series of powerful flashes or thrills, which, falling on the fog after intervals of darkness, would be likely to arrest the attention of the mariner. Mr. Inglis, the Secretary of the Trinity House, promptly replied that my letter had been written under a misapprehension. The flashes, or thrills, recommended by me had, he said, been in use at St. Catherine's Point ever since 1888. This I knew to be wrong, for to my certain knowledge no flashes were exhibited at the Point in January, 1889. But, on the strength of Mr. Inglis's statement, I assumed that they must

Digitized by Google

have been introduced subsequently, and that the error in his letter was simply a venial one of date. I am, however, concerned to find, upon inquiry, that the mistake is of a much more serious character. The changes which I assumed to have been made were never made; the electric light at St. Catherine's Point is to-day what it always has been—a quick revolving light, which never suffers extinction. No flashes such as I recommend are associated with the signal. The gravity of Mr. Inglis's misleading statement is vastly enhanced by the fact that, trusting to the accuracy of his informant, Sir Michael Hicks-Beach gave currency to the error by repeating it in the House of Commons on February 12th, thus authoritatively diffusing it throughout the civilised world. The flashes for which I contend, and have for years contended, are pulses of light, leaping instantaneously out of darkness, and falling as suddenly into darkness when their work is done."

The City Lighting.—At the meeting of the Commissioners of Sewers on Tuesday last, Mr. C. D. Harris asked permission to take at this junction the Solicitor's report on the subject of the existing electric lighting contracts. The Solicitor then submitted his report, which showed that the dates of the completion of the contracts for the Eastern and Central Districts had expired. The Clerk read a letter he had received from the City of London Electric Lighting Company, who stated that the total length of work in the Eastern and Central Districts was 31,105 yards, and of this 24,388 yards had been completed, and at the rate of progress the work would be finished in three weeks. The date of the contract for the Western District would expire on November 5th next, but the Company hoped that the work would be completed before that date. Mr. C. D. Harris asked leave to bring forward a motion to the effect that the whole question should be considered by a committee of the whole Court, with a view to inquiring into the non-completion of these contracts. Mr. Johnson strongly opposed the proposition, saying it would be a most dangerous thing to do. It was impossible for the work to be done any quicker, or the whole traffic in the City would be stopped. The Court refused permission for the moving of the resolution, by 25 votes against 15.

A Fatal Electric Shock.—On Monday last the coroner for Kent was engaged at Chatham in investigating the circumstances attending the death of Albert George Jay, aged 26, engaged as a salesman by a firm of Chatham tailors. It appeared from the evidence that shortly before six o'clock on Friday evening the workmen of the Chatham, Rochester, and District Electric Lighting Company were summoned to the shop, which is lighted by electricity, to remedy a defect. Whilst the company's foreman was in the cellar beneath the shop examining the fuses, he slipped, fell with his hand on the wire, and received a severe shock. Shortly afterwards sparks coming from the direction of the transformer, and Jay, thinking the premises were on fire, rushed into the cellar with an iron bar, to "beat the fire out." As he entered the cellar he held up the bar in a striking attitude, but immediately afterwards dropped the bar and fell back in another man's arms. He was removed from the cellar, and died in ten minutes. Dr. Walter Buchanan stated that he had made a post-mortem examination of the body, assisted by three other medical men. The appearances were entirely consistent with death from an electric shock. The following was the verdict:—"The jury are unanimously of opinion that the deceased came to his death through an electric shock by misadventure; and in their opinion greater care should be observed by the Electric Lighting Company in providing switches to turn off the current from the various circuits of wires as occasion requires, and that they should strictly prohibit workmen from executing repairs whilst the current is on."—A letter from the Secretary of the Chatham, Rochester and District Electric Lighting Company will be found in our Correspondence columns.

Electric Haulage in German Mines.—At present very little is known, says the *Colliery Guardian*, concerning the cost of electric traction in mining operations; but the following particulars regarding three German mines will, doubtless, be found of more than usual interest. The installation in the Hohenzollern mine, carried out by Siemens and Halske, comprises two main roads, each traversed by an electric locomotive. The current is conveyed to the bottom of the shaft, a depth of 650ft., by means of four insulated armoured cables. The conductors are carried overhead, and are supported from the roofs of the roads. Each locomotive is propelled by two electromotors, imparting a speed of from 40ft. to 50ft. per second to a train of about 20 tons on a line 26in. gauge. The generating plant consists of a dynamo giving 140 amperes at 300 volts. In the Zaukerada and Stassfurt mines the locomotives were built by the General Electricity Company of Berlin. In each of these cases the generating dynamos yield 75 amperes at 160 volts. In these three instances, by the employment of separate steam-engines and of a *personnel* solely attached to the working of the plants, it has been possible to arrive at the cost price tolerably accurately. The following are the figures:—

Working conditions.	New Stassfurt.	Zaukerada.	Hohenzollern.
Average distance hauled, in feet ...	2,600	2,340	2,450
Average number of wagons per day.	400	400	900
Weight of coal per wagon in cwt....	16	9¾	11

The working expenses, per waggon, comprising the wages of engine-tender on the surface, operating of the locomotives, cost of coal for the production of steam, sundries, repairs, interest and depreciation at 15 per cent., amount to 1d. at New Stassfurt, to ⅜d. at Zaukerada, and to ⅜d. at Hohenzollern. The expenses per ton mile were respectively 2½d., 1⅜d., and 1¼d. At the Richter pit the working of a roadway 3,075ft. long, by electric traction, necessitated an initial expenditure of £2,500, the steam being supplied by boilers already on the surface. The daily output is 1,200 loads of 13cwt. each. The annual working expenses at this mine amount to ⅞d. per ton mile.

The Effect of Longitudinal Magnetisation on the Interior Volume of Iron and Nickel Tubes.—In a Paper presented to the Royal Society of Edinburgh last summer Professor Cargill G. Knott establishes the broad fact, that the internal capacity of iron and nickel tubes alters appreciably when the tubes are magnetised longitudinally. The tubes experimented upon were 34·8cm. long, and were all about 3cm. external diameter. One iron tube had an internal diameter of 1cm, and another of 2cm. When experimented with, each tube was tightly corked at both ends, and through the one cork a fine capillary glass tube projected. The tube was filled with alcohol coloured with cochineal. The changes of volume were measured by the movement of the end of the liquid column in the capillary tube. This was viewed through a microscope. A movement in the tube through a distance equal to one division of the microscope micrometer meant a change of volume of $7{\cdot}2 \times 10^{-6}$ cub. cm Field strengths of 50, 125 and 250 units were employed. For the iron tubes, it was found that the transverse contraction always exceeded the longitudinal extension, so that there was on the whole a diminution of the internal space. There was evidence of the contraction attaining a maximum, which, in the case of the thinner walled tubes occurred in a field not far removed from the field which produced the maximum extension. For the nickel tube, formed by rolling up a sheet of ordinary commercial nickel to a convenient size, the transverse *expansion* differed so slightly from the longitudinal contraction, that the change of volume of the internal space, though of the same order of quantity as the corresponding change in the iron tubes, was a very small fraction indeed of the change that would result from the longitudinal contraction acting alone. In low fields, the longitudinal contraction overbalanced the transverse expansion, causing a compression. This compression reached a maximum about field 60, and then fell off first slowly, then more rapidly. About 140 it became zero, and changed sign in higher fields. In field 260 a very distinct dilatation was produced about equal to the maximum compression obtained in field 60. The rapid changes of temperature of the liquid in the heart of the magnetising coil, when the high currents were used, made accurate measurements of the changes of volume impossible; but there was no doubt as to the fact of the change of sign in the compression when the field was taken high enough. In an experiment with a glass tube substituted for the iron or nickel tube, no effect was produced; so that the alcohol itself was uninfluenced by the magnetising force. An experiment was also tried with a current of seven amperes passed along the iron tubes, so as to cause a circular magnetisation of the outer circumference. No change of volume was observed.

THE DETERMINATION OF CURRENTS IN ABSOLUTE ELECTRO-MAGNETIC MEASURE.

BY G. F. C. SEARLE, M.A.

(*Continued from page 404.*)

§ 66. **Choice of Instruments.**—We now pass on to the consideration of the various parts of Lord Rayleigh's work, and will deal first with his method of measuring the current in C.-G.-S. absolute measure. In the use of any instrument for the determination of currents in absolute measure we have to make observations of two classes. To the first class belong all the observations which are necessary for the determination of the "constants" for the instrument; while in the second class we place the observations which have to be made during the passage of the current. The quantities belonging to the second class are variable, depending upon the strength of the current. In order that we may obtain the most accurate results, the following conditions should be fulfilled:—(1) The "constants" of the instrument should be of a very permanent character, and should not be appreciably affected by any slight relative displacements of any parts of the apparatus. (2) No quantities over whose variations we have no control should be included among the "constants" of the instrument. (3) The number of observations which have to be made with "first-class accuracy" should be as small as possible, and the quantities to be determined in absolute measure should be chosen from such as are most easily observed with accuracy. We will now discuss the principal current measurers; and examine how nearly they comply with these conditions.

§ 67. **The Tangent Galvanometer.**—The tangent galvanometer fulfils conditions (1), since a properly constructed coil is not liable to change its dimensions, and since the centering of the needle is easily effected with sufficient accuracy. It fails in (2), since a knowledge of the Earth's Horizontal Magnetic Force is required, this being a quantity which is difficult to determine, and which is subject to incessant variations. It is faulty in respect to (3), since the determination of the mean radius of a coil by the measurement of the successive layers is a difficult operation, and one which it is impossible to repeat. The absolute angle of deflection has to be observed, and this is also a difficult operation (*see* § 27.)

§ 68. **The Electro-Dynamometer.**—The electro-dynamometer is an improvement upon the tangent galvanometer as regards the earth's magnetic force, since by taking the observations properly this quantity can be eliminated; but the instrument is faulty as regards (1) because although the coils themselves are of a sufficiently permanent character, still its "constants" include the length and distance apart of the bifilar suspending wires, which will be different each time the instrument is set up afresh. It is true that these quantities have not to be observed directly, but still they affect the time of swing of the suspended coil, which has therefore to be determined on each occasion when a current has to be measured. The difficulties of the measurement of absolute angles and of the determination of the absolute mean radius of a coil again make their appearance. But besides the quantities which have to be determined in absolute measure, there are a large number of ratios which have to be measured. The theory of the electro-dynamometer was discussed in §§ 50, 51, 55, and it was pointed out that the very appearance of the final formula was a sufficient indication that the instrument, when applied to the "absolute" measurement of a current with all attainable accuracy, labours under serious disadvantages.

§ 69. **The Current Weigher.**—We will now turn to the current weigher, or electric balance, and will briefly consider how closely it conforms to the ideal conditions laid down in § 66. In this instrument a moveable coil suspended from one arm of a balance lies with its plane horizontal, and midway between a pair of fixed coils whose planes are also horizontal. The current is sent in opposite directions through the fixed coils, so that the suspended coil is attracted towards one and repelled from the other. The general arrangement may be seen from Fig. 43 (§ 48), which is now reproduced as Fig. 51. This figure, however, only shows *one* fixed coil.

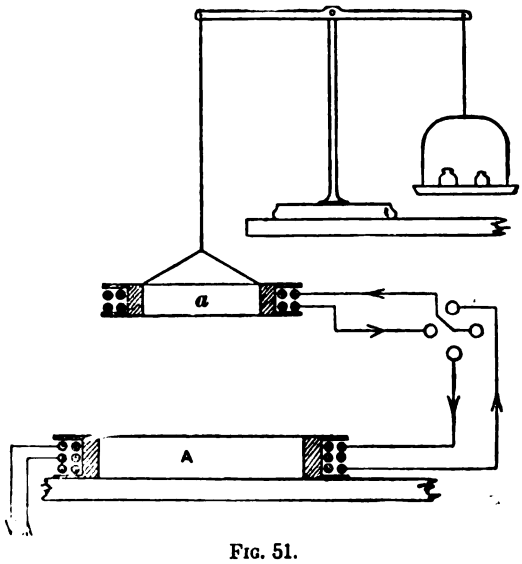

FIG. 51.

§ 70. **Lord Rayleigh's Instrument.**—Lord Rayleigh, in his work on "The Electro-Chemical Equivalent of Silver,"* employed an instrument with *two* fixed coils. Fig. 52 will serve to give an idea of the apparatus.† The two fixed coils, A_1, A_2, are those of the electro-dynamometer "constructed by the Electrical Committee of the British Association."‡ When the coils are to be used in the electro-dynamometer they are placed so as to have their planes *vertical* instead of horizontal (*see* § 51). A drawing of this electro-dynamometer will be found in Maxwell, Vol. II., p. 339. The fixed coils are wound in channels formed at the ends of a hollow brass cylinder, and thus the distance between them is absolutely fixed and their parallelism is ensured. The aperture in the front of the drum (Fig. 52), through which the suspended coil is seen, is to allow the passage of the bifilar suspension in the electro-dynamometer. The current is led to and from the suspended coil by flexible copper wires. The connecting wires are not shown in Fig. 52.

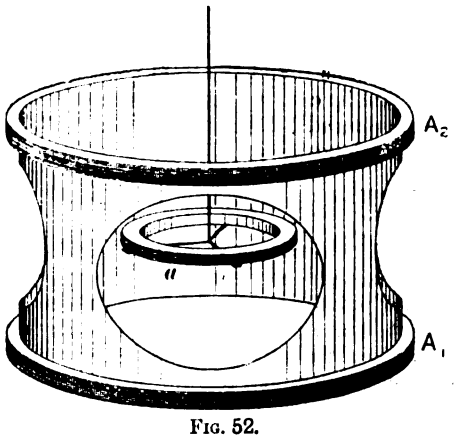

FIG. 52.

The current passes in series first through the two fixed coils and then through the suspended coil. The suspended coil, *a*, was wound on an ebonite bobbin by Lord Rayleigh; it is supported by a light brass framework which is suspended from an arm of a balance. The coil is provided with levelling screws

* *Phil. Trans. Royal Society*, 1884, Part II.

† The principal data of Lord Rayleigh's instrument were roughly as follows:

The Fixed Coils.

A = mean radius = 24·8cm.
2B = distance between mean planes = 25·0cm.
Number of turns of wire on each coil, 242.

The Suspended Coil.

a = mean radius = 10·2cms.
Number of turns of wire = 242.
Mass of wire and ebonite ring = 575 grammes.
Force experienced for 1 ampere = 4·5 grammes weight.

‡ Maxwell, Vol. II., § 725.

Digitized by Google

resting on the brass framework, and by means of these the plane of the coil can be made horizontal. These screws are not shown in the figure.

In setting up the apparatus the suspended coil is adjusted so as to be co-axal with the fixed coils, and to have its mean plane horizontal and midway between the mean planes of the fixed coils when the balance is free and its pointer is at the zero of its scale. To measure a current a determination is made of the mass, which must be placed in the pan of the balance in order to bring the pointer to its zero position. The current is then reversed in the fixed coils, but maintained in the same direction through the suspended coil. A different mass will now be required to establish equilibrium. The weight of the difference of the masses in the two cases is equal to twice the electromagnetic force experienced by the suspended coil. The difference of mass is proportional to the *square* of the current.

§ 71. **Fulfilment of Conditions.**—The coils employed in this instrument being wound on carefully made bobbins have a very substantial and permanent character, and are very unlikely to undergo any change, so that the current-weigher conforms to the first part of condition (1). By placing the suspended coil midway between the two equal fixed coils the instrument is made to satisfy the second part of condition (2), viz., that the "constants" of the instrument should be unaffected by any slight relative displacement of any parts of the apparatus. For if F is the force between two co-axal coils of radii A, *a*, placed at a distance B + *x* apart, the current in each coil having unity for its value, we have, by Taylor's Theorem,

$$F_1 = F_0 + x\left(\frac{dF}{dx}\right)_0 + \frac{x^2}{1\cdot 2}\left(\frac{d^2F}{dx^2}\right)_0 + \ldots\ldots$$

where F_0 is the force when the distance between the planes of the coils is B, *i.e.*, when $x = 0$. The subscript $_0$ atttached to the differential coefficients indicates that they are the values of $\frac{dF}{dx}$, &c., when x is put = 0 *after* differentiation. The force between the coils when their distance apart is B − x is

$$F_2 = F_0 - x\left(\frac{dF}{dx}\right)_0 + \frac{x^2}{1\cdot 2}\left(\frac{d^2F}{dx^2}\right)_0 - \ldots\ldots$$

If then we place the suspended coil nearly midway between two equal coils fixed at a distance 2 B apart, and send the current in opposite directions round the fixed coils, so that their effects upon the moveable coil are added together, we find for the total force experienced by the suspended coil when at a distance x from the central position

$$F = F_1 + F_2 = 2\left\{F_0 + \frac{x^2}{1\cdot 2}\left(\frac{d^2F}{dx^2}\right)_0 + \ldots\right\}$$

Thu the error introduced on account of an inaccurate placing of the suspended coil depends upon the *square* of the inaccuracy, so that if the adjustment is done with a reasonable amount of care the error is quite negligible. In this way any anxiety as to the effect of slight relative displacements is entirely removed, and condition (1) is completely fulfilled.

As regards condition (2) the force experienced by the suspended coil is measured by balancing it against the attraction of the earth on the masses which are put into the pan on the other side of the balance. The estimation of the force thus depends upon the value of gravity. But "*g*" for any given locality is known with great accuracy, and any variations in its value at that locality are so small as to escape detection by the most delicate and accurate observations. Thus condition (2) is satisfied.

We have now to consider condition (3). The quantities on which the force developed by unit current depends are the mean radii A, *a*, of the fixed and moveable coils, and the distance 2B between the two fixed coils. We neglect for the present the measurements of the channels in which the wire is wound, since these only appear in some small corrections of the *second* order. We shall show that if the instrument is properly designed, a *very accurate* knowledge of B is unnecessary, and that the *ratio* of the radii A, *a* is the only quantity for which careful observation is requisite.

The electro-magnetic force experienced by the suspended coil when a current i flows through the instrument is $2i^2 dM/dx$ dynes, where M is the coefficient of mutual induction for the suspended coil and *one* of the fixed coils, and x is measured along the common axis of the coils. It was explained in § 42 that M is a "length" in the electro-magnetic scheme. Thus dM/dx being the ratio of one length to another is a pure number, and independent of the *absolute* dimensions of the system, so that its value involves only the *ratios* A/a, B/a. Let us write $A/a = \eta$, $B/a = \zeta$. Then dM/dx is some function of η and ζ, let us say $dM/dx = f(\eta,\zeta)$. Then $d\zeta = \frac{dB}{a} - \frac{Bda}{a^2}$, so that

$$df = \frac{df}{d\eta}d\eta + \frac{df}{d\zeta}d\zeta = \frac{df}{d\eta}d\eta + \frac{df}{d\zeta}\left(\frac{dB}{a} - \frac{Bda}{a^2}\right).$$

This equation shows us how the variations of f are governed by the variations of A, B, and a. Now, if keeping the radii of the coils unaltered, and always placing the moveable coil midway between the fixed coils, the latter are placed at such a distance apart that the force experienced by the suspended coil is a maximum, no *small* change in B will have any effect upon f. Hence in this case the coefficient of dB in the above equation must vanish, so that $df/d\zeta = o$. The equation then reduces to $df = \frac{df}{d\eta}d\eta$, indicating that f is simply a function of η, i.e., of the ratio A/a.

(To be continued.)

A NEW MODE OF EMPLOYING CONTINUOUS-CURRENT TRANSFORMERS.*

BY W. C. RECHNIEWSKI.

Electric lighting central stations can only economically serve a certain area of which they are the centre, and this area is the more limited the lower the pressure employed. Occasions, however, arise when it would be an excellent thing to overstep the usual limit, and supply lamps at a greater distance. There are several ways of solving the problem. Let us take for example a 110-volt station. Such a station can supply lamps to a distance of 600 to 700 metres. To go further we must have a higher voltage, either alternating or continuous at the station, and transform this higher voltage down to 110 volts at the point of consumption. If we employ alternating currents there is the inconvenience of introducing into the station a type of machine totally different to the 110-volt continuous-current dynamos. These alternators cannot act as a reserve to the continuous-current generators, and we complicate the plant and render the use of accumulators impossible. Moreover, the two low-pressure networks cannot be connected together, since one is on the alternating and the other on the continuous-current system. It would therefore be better to use continuous-current transformers. Unfortunately, these machines are expensive, and their efficiency rarely exceeds 80 to 85 per cent. There is, however, an arrangement which permits of a 50 per cent. reduction in first cost and total loss.

Let us consider a simple case, and such as often arises in practice. A 110-volt central station, as I have already pointed out, cannot economically light an area of more than 600 to 700 metres radius. Let us suppose that there are 1,000 lights 1,800 metres distant requiring current; 1,000 10-c.p. 40-watt lamps mean 40 kilowatts (110 volts × 350 amperes). We can feed this group of lamps either by a feeder in which we may make up our minds to lose 20 to 30 per cent. of the energy transmitted, and which by reason of its large cross-sectional area and great length will be very costly; or by continuous-current transformers. In the latter case the following arrangement would be the most economical. In series with the existing battery of 110-volt machines, we might place a similar 130—140 volt machine (*see* figure);† we should then have a

* From *L'Industrie Électrique*, February 10, 1892.
† From the *Bulletin Soc. Int. des Electriciens.*

Digitized by Google

pressure of 240—250 volts at the central station. The current being transmitted along the feeder at this high pressure we could diminish the weight of copper by one-half, and yet only lose 10 to 15 per cent. in the conductor.

Deducting the volts lost in the line, we should have at the feeding point about 230 volts. Here let the current be passed through a 120/110 transformer. There would still remain available 110 volts after the current had traversed this transformer. But the secondary of the transformer also supplies current at 110 volts pressure; we can, therefore, place the two sources in parallel (*see* figure).

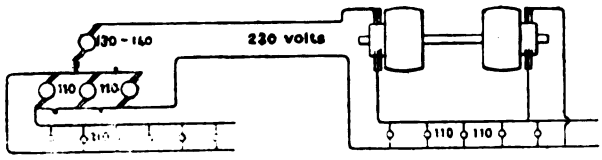

Fig. 1.

In short, the transformer has, so to speak, enabled us to lower the voltage of one portion of the current to that of the other, and to place in parallel what was formerly in series.

We therefore only transform one-half of the electric energy. The cost of the transformer is consequently one-half of what it would be had we to transform the total energy. Moreover, the loss of energy inevitable in every transformation only affects one-half of the energy supplied, so that this loss is one-half.

This system does not involve the introduction at the central station of machines of a type different to those already installed there. The device may also be made use of when a feeder becomes too small; instead of laying a new feeder we can double the voltage.

The regulation of the volts at the lamp terminals is automatic. So long as we maintain 230 volts between the two conductors we shall have 110 volts at the lamps, whatever the load, whatever the sudden variations. On no load, *i.e.*, when no lamp is alight, the two armature windings are in series, and generate a back pressure of 230 volts. When lamps are turned on, the current in the secondary reverses and begins to supply current concurrently with the direct circuit.

It is evident that instead of doubling the E.M.F. we could increase it three-fold or four-fold by the same process; but the advantage of the combination would then be less evident. The same idea can be applied to three, four, or five-wire systems. Fig. 2 shows the connections in the case of a three-wire net work. The current could be transmitted to the point of consumption at a pressure of 440 volts; it could then be passed through the primary of a transformer, which would absorb 220 volts; the secondary of which would be in two distinct portions,

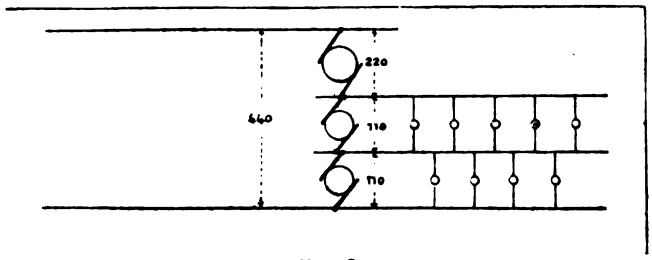

Fig. 2.

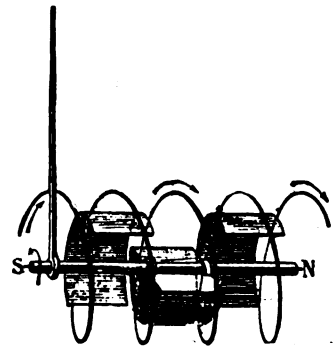
each giving current at 110 volts. The two secondaries would feed the three-wire network, as any two ordinary generators would do, with the difference that the primary current, after leaving the primary circuit, would enter the system by one external wire and leave it by the other. In this case the two secondary circuits play a double part. First of all they act as two generators actuated by the primary circuit, and furnishing current to the lamps. Secondly, they act as compensators, and equalise the potentials of the three wires in a manner analogous to the compensators used in the Clichy Sector. (See *The Electrician*, February 5th, p. 359.)

Let us now see how the question looks from the economic point of view. Take, again, our 110-volt station as an example, and consider, first of all, the results of using a feeder in which we are to lose 20 per cent. of our energy. To feed 1,000 10 c.p. 110-volt lamps 63 amperes are required. With a 20 per cent. loss in the conductor, and the lamps being 1,800 metres distant, we should require a cross-sectional area of 790 square mm. ($1\frac{1}{5}$ square inches), or 25,200 kilogrammes ($25\frac{1}{4}$ tons) of copper. If we employ the plan I have just sketched out we can use double the voltage. To render the results comparable, let us assume the same *total* loss of 20 per cent., *i.e.*, 10 per cent. in the line and 10 per cent. in the transformer. Under these conditions the line will only weigh 12,600 kilogrammes, but a 20,000 watt transformer will be required. The price of such a transformer will certainly not exceed 6,000fr., while the cost of 12,600 kilogrammes of conductor, including the cost of laying and insulating, will certainly exceed 40,000fr. The saving we thus see may be sufficiently large to justify the adoption of the method I have described.

A HARTMANN AND BRAUN AM-VOLTMETER.

The well-known German firm of Hartmann and Braun, a description of whose Frankfort Exhibition display appeared in our issue of October 30, 1891, are making ammeters and voltmeters on the Evershed principle. In the accompanying figure, which we take from *La Lumière Electrique*, it will be seen that these instruments contain a magnetising coil within which



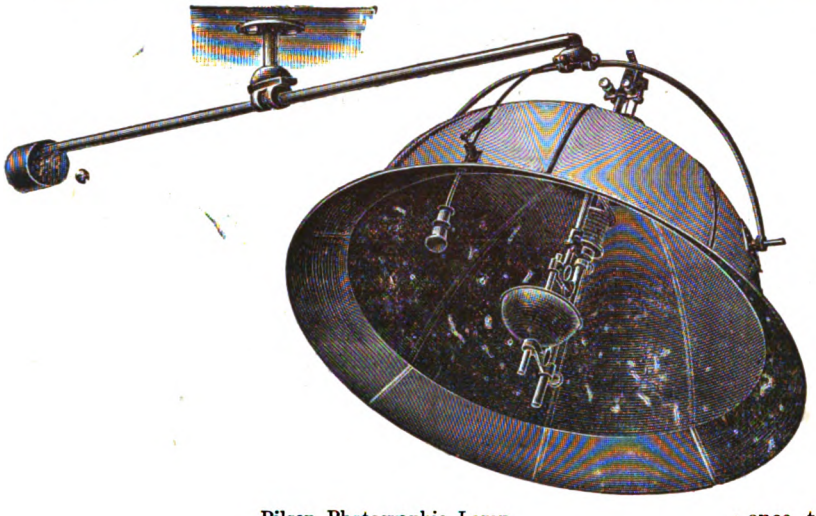
there are thin semi-cylindrical iron shells arranged a little less than their widths apart. Similar shell-shaped pieces of iron are arranged along the axis N S of the needle, filling the intervals left between the fixed segments and slightly overlapping them. When a current is passed through the coil the movable segments are attracted upwards, the force of attraction being balanced by that of gravity. By adjusting the relative positions of the segments it is possible to obtain either wide deflections between narrow limits of pressure values, or on the other hand almost equal divisions all along the scale. The coil consists of two parts, one of copper wire and the other of nickeline, so as to compensate the variations of resistance caused by changes of temperature, and render the indications of the instruments almost independent of the temperature. The opposing force being gravity, it remains absolutely constant, and the iron being very thin its residual magnetism is very small.

THE PILSEN PHOTOGRAPHERS' LAMP.

In order to meet not only the demand for arc lamps, but the exacting and varied requirements of photographic artists, the Pilsen Electric Company have designed a lamp which is now in daily use in several large photographic studios. The apparatus consists of a specially constructed Pilsen lamp, mounted in a large dome reflector, 4ft. in diameter, and hung from a counterpoised arm, as shown in the illustration. The arm is about 8ft. long, and the lamp can be set at any desired radius

Digitized by Google

from the centre. Ball and socket joints are provided both at the centre support and at the extremity of the arm, connection with the lamp being made by flexible cables. The dome swings on trunnions, and can be set at any desired angle by a clamp, but a great variety of positions can be used by means of the two ball and socket joints alone. The lamp is usually inclined at about 45deg. The lower carbon is the positive, and is 20 millimetres in diameter; a very soft-cored carbon is used, a special core preparation being filled into hollow carbons by the Pilsen Company. The negative carbon is 15 millimetres. A current of 50 amperes is carried, and the volts vary from 47 to 56. Considerable difficulty was experienced at first with unstable arcs, which ran round the edge of the carbon roaring and flaring. This has been overcome by careful attention to the



Pilsen Photographic Lamp.

freedom of the feed and to the quality of the positive carbon. A 9in. enamelled iron bowl reflector serves to screen the direct rays of the arc from the sitter, and the main part of the light is thrown directly on the whitened interior of the dome. A very well diffused light is thus obtained.

THE ASSOCIATION OF CHAMBERS OF COMMERCE.

At the meeting of the members of this Association on Wednesday:—

Coast Communications.

Mr. Moxey (Cardiff) moved:—

"That in the opinion of this Association it is needful, for the safety of life, that the lighthouses, lightships, and coastguard stations should be in telegraphic communication with each other, and the general telegraphic system of the country where practicable."

Sir Michael Hicks-Beach, M.P., who was warmly cheered, said: I am deeply interested in the question which you have been discussing, and, so far as my personal opinion goes, I am entirely at one with you in the principles which you hold. You favoured me last year with a list of lighthouses where telegraphic communication was needful, and I was glad to find that in some of the places named there was already an existing telegraphic communication. In the others I should certainly have been prepared to act, but I could only act as the administrator of a fund which is raised from the light dues upon shipping: and therefore I thought it only right before acting to place myself in communication with the Chambers of Shipping as representing those by whom this fund is paid, and to ascertain whether in their judgment I should be justified in devoting part of it to that purpose. Not unnaturally, the Chambers of Shipping demurred to such an expenditure being placed entirely upon their shoulders. They held that it was a matter of national interest, and that, therefore, the nation ought to pay for it. I, therefore, could proceed no further in the matter, so far as the Mercantile Marine fund was concerned. If I had been able to do so I think we might have seen by this time some communications established where they do not exist to-day; but, however, I daresay nothing has been really lost, because in the meantime the attention of the public has been very much called, by yourselves and by others, to this question, and there is, no doubt, a wave of public feeling on it which I do not doubt will carry it to the conclusion which you desire. I do not at all wish now to go into the difficulties of the subject. These difficulties exist and cannot be ignored; but I understand it has been generally felt to-day that, in the first place, a commencement should be made with the principal landfalls and coastguard stations, and that an inquiry is necessary to decide how far these communications can be established with our rock lighthouses, our lightships, and places of that kind. You must remember, gentlemen, that although Chambers of Commerce may pass resolutions year after year, and although the Chambers of Shipping may entirely agree with them, as they do agree with them, in the opinion that this is a matter which should be undertaken without further delay at the cost of the nation, yet the proper tribunal by which the Government should be authorized to undertake such an expenditure is the House of Commons; and therefore I think it must be satisfactory to you to know that within a few days Sir Edward Birkbeck will bring this question under the consideration of the House of Commons; that upon that motion Her Majesty's Government will of course be prepared to state their views; and that then the House of Commons, representing the taxpayers of the country, will be able to express a definite opinion as to whether, as a matter of principle, this expenditure should be incurred, and, if it does so, of course to assure the Government of its support. I can assure you that I sympathize with you in this matter.

The Chairman (Colonel Hill, C.B., M.P.) expressed his gratification at the terms in which the discussion had been carried on. The Association could not possibly expect the President of the Board of Trade to say more than he had said upon the subject, and they would only be too glad if the Prime Minister would change the promised Committee into a Royal Commission. He congratulated the Chambers on the fact that something was to be done in the matter. He hoped no more would be heard of the bogie about the lighthouses being blown down in time of war.

Sir Edward Birkbeck, M.P., stated that every member of Parliament who had communicated with him in reference to this question was unanimously in favour of a Royal Commission to inquire into the question of outlying rock lighthouses and floating light-vessels. In regard to the general question of coast communication, they said that the matter would be dealt with by the House of Commons in a national point of view, and he had only heard of one member of the House of Commons who was antagonistic to the proposition. Every member of Parliament who had gone into the question was going to support his motion.

The motion was then carried unanimously.

Telegraph Reform.

Mr. Brittain (Sheffield) brought forward the subject of the delivery of telegrams, and moved:—

"That, in the opinion of this Association, it is incumbent upon the Post Office authorities to give the same facilities, in every respect, for the delivery of telegrams as they now afford the public for the delivery of letters; and that the Department should no longer refuse to attempt to deliver telegrams in case there might be some slight error or insufficiency in the address which would not prevent delivery in the case of a letter; and that a deputation from the Association do wait upon the Postmaster-General to confer with him upon the subject."

Upon this the Chairman said he had received the following important letter:—

"General Post Office, London, March 7th.

"Sir,—I am directed by the Postmaster-General to acquaint you that the memorial of the Association of Chambers of Commerce on the subject of the delivery of telegrams, which you submitted on the 11th ult., has received his careful consideration. In reply, I am to say that the memorialists are under a misapprehension in supposing that the officers of this department have been instructed not to attempt to deliver telegrams in cases where an obvious slip has been made in the address. On the contrary, they are enjoined to make the utmost efforts, consistently with the exigencies of telegraph business, to effect the delivery of all telegrams. The fact that an address which may suffice for a letter is not necessarily sufficient for a telegram is not due to any difference in the spirit in which the Postal and Telegraph Services are worked, but to the fact that the conditions under which letters and telegrams are dealt with are essentially different. As stated by the late Mr. Raikes, in answer to a question in the House of Commons, 'the object of the telegraph service is instant action, and it would not be possible, without serious injury to persons making use of it, to despatch messengers on voyages of discovery, which would necessarily very seriously retard the delivery of other telegrams.' In the case of letters bearing addresses which cannot be readily identified, opportunities offer for making special inquiry as to their disposal, without delaying other letters, but in the case of telegrams any inquiry must be made at once; so that the attempt to deliver one telegram, which may prove unsuccessful, will in all probability lead to the delay of several. Another point is that telegrams are not nearly so numerous as letters. The large amount of correspondence passing through the hands of postmen soon familiarises them with the names and addresses of persons residing in the district in which

Digitized by Google

they deliver; but it is obvious that the same opportunities are not enjoyed by telegraph messengers, the delivery of a telegram being a more infrequent occurrence. With regard to the first of the two illustrations brought forward by the memorialists—namely, the supposition that if a telegram happens to be addressed to No. 3 instead of No. 2 in a given street, the regulations preclude its delivery to the person for whom it is intended, although his correct address is well known—I am to explain that, in point of fact, no pains are spared to effect delivery when a precise and apparently a complete address is given. Messengers are instructed to try such telegrams at several houses, if necessary, and frequently when the telegram is brought back to the office undelivered it is sent out a second time for further trial. In the case which the memorialists had particularly in view it appears that the addressee was a visitor at a watering place during the season, and in these circumstances the failure of the telegram in consequence of the error in its address can readily be understood. As regards the other case—that as to the sufficiency of the address 'Onslow House, Sheffield'—I am sorry to say that Sir James Fergusson considers that the postmaster of Sheffield acted rightly in informing the secretary of the Chamber of Commerce that there could be no guarantee that telegrams so addressed would be duly delivered. Bearing in mind the essential difference between postal and telegraph work, Sir James Fergusson thinks it not unreasonable to expect that in a large town like Sheffield a better address should, where possible, be given for telegrams than the name of a private house followed by the name of the town. I am told that the fact that a number of telegrams (not, indeed, forming any considerable proportion of the total) have to be treated as insufficiently addressed is due, not, as Sir James Fergusson thinks, to any want of elasticity in the Department's delivery arrangements, but to causes over which the Department has no control. Sir James Fergusson refers to the use of names instead of numbers for houses, and the want of system in naming, and even in numbering streets. These difficulties, which necessarily impede, more or less, the delivery of correspondence of all descriptions, are particularly felt in the metropolis. There are hundreds of streets in the suburbs composed of rows of houses which are not numbered, and can only be identified by such names as 'The Limes,' 'Woodville,' 'Belmont,' &c., and great difficulty also arises from the number of streets which bear the same name. A reference to the 'London Delivery Book' (a compilation used as a guide in the delivery of telegrams) shows the existence of 34 King-streets, 35 Queen-streets, 19 Duke-streets, and 24 New-streets; there are 29 Victoria-places, 33 Victoria-roads, seven Victoria-streets, and 44 Victoria-terraces; the name 'Park-cottages' appears 24 times, 'Park-place' 31 times 'Park-road' 29 times, 'Park-street' 14 times, 'Park-terrace' 41 times, and 'Park-villas' 51 times. While this state of things continues, Sir James Fergusson fears that cases of non-delivery can never be reduced below a certain *minimum*. The local authorities might, however, do much to mitigate the evil, if, indeed, it cannot be entirely removed. With that object in view the Post Office has from time to time exercised its influence with the local authorities, but the circumstances are such that the remedy rests primarily with the public. "I am, &c., "J. C. LAMB."

The motion was thereupon withdrawn.

Telephones.

A long discussion ensued upon the telephone system of the country; and on the motion of Mr. BROWN (Plymouth), seconded by Mr. WAKE (Leicester), it was agreed unanimously:—

"That in the opinion of this Association it is desirable, for the due development of the telephone system of the country, that Government be asked to take it over: provided, however, that satisfactory assurances can be obtained that the Government officials are prepared to work the system and extend it with vigour and efficiency."

Underground Telegraph Wires.

On the subject of the protection of telegraph wires it was agreed, on the motion of Mr. GROSER (Plymouth), seconded by Mr. STEIBELL (Nottingham):—

"That in the opinion of this Association it is of great importance that the telegraph wires of the country should be protected by being laid underground or in some other effective manner, so as to prevent the serious interruptions of telegraphic communication that now take place through storms and the consequent breakdown of wires and poles; and that the Executive Council be asked to take such steps as they may consider most desirable to impress on the Government the importance of this matter receiving attention."

The motion was carried, but not by a sufficient majority to allow of any action being taken.

The Chambers discussed questions of fire assurance, and adjourned until Thursday morning.

At the banquet in the evening, Sir J. GORST took occasion to mention that in the course of the present Session the House of Commons would be asked to vote a sum of money to begin the work of establishing telegraphic communication with the lighthouses around the coast. He believed that important work should be now commenced, and he did not think many years would elapse before satisfactory communication was established.

THE GENERAL ELECTRIC COMPANY.—We are pleased to learn that the damage done by the fire at this Company's Manchester works is only very slight, and that arrangements have been made by which the regular output will not be seriously interfered with.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, March 11th.

LONDON CHAMBER OF COMMERCE.

3.30 p.m. Meeting at the Mansion House: To consider the Chicago Exhibition.

PHYSICAL SOCIETY.

5 p.m. Ordinary Meeting. Papers to be read: (1) "Thermodynamics and the Action of Light on Silver." By H. M. Elder. (2) "On Choking Coils." By Prof. J. Perry, F.R.S.

CITY AND GUILDS OLD STUDENTS' ASSOCIATION.

8 p.m. Meeting at Central Institution. Paper to be read: "The Behaviour of Insulating Materials under the Action of High Potential Differences." By H. B. and W. Fox Bourne.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Japanesque." By F. T. Piggott.

SATURDAY, March 12th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Matter at Rest and in Motion." By Lord Rayleigh, F.R.S.

MONDAY, March 14th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture. III.—3. "The Uses of Petroleum in Prime Movers." By Prof. William Robinson, Assoc. M.Inst.C.E.

TUESDAY, March 15th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "Petroleum Engines." By Prof. W. C. Unwin, F.R.S.

WEDNESDAY, March 16th.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Ordinary Meeting. Presidential Address by Dr. C. T. Williams. Exhibition of instruments, etc.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Iceland." By Tempest Anderson, M.D.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Ordinary Meeting.

THURSDAY, March 17th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting.

CHEMICAL SOCIETY.

8 p.m Meeting. Papers to be read.

FRIDAY, March 18th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Modern Satire in Black and White." By George du Maurier.

SATURDAY, March 19th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Matter at Rest and in Motion." By Lord Rayleigh, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

blished every Friday, Price Fourpence: Post Free, Fourpence Halfpenny
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co." *All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

NOW READY.

STEEL-PLATE PORTRAITS

Of W. H. Preece, F.R.S.; Michael Faraday (out of print); Sir John Pender, K.C.M.G.; Sir William Thomson, F.R.S. (Past-President of the Institution of Electrical Engineers); C. H. B. Patey, C.B. (Late Secretary of Telegraphs, G.P.O.); Dr. John Hopkinson, F.R.S. (Past-President of the Institution of Electrical Engineers); Dr. Oliver J. Lodge, F.R.S., Prof. William Crookes, F.R.S. (Past-President of the Institution of Electrical Engineers); Willoughby Smith (out of print); Prof. von Helmholtz and Prof. W. E. Ayrton (President of the Institution of Electrical Engineers), have been issued as Supplements to "THE ELECTRICIAN."

A few Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, 4s. 6d, carriage paid (U.K.)

A NEW AMERICAN SUPPLY STATION.

It might have been imagined that with the development of electrical engineering some convergence between English and American practice would take place; but it appears that an interchange of ideas and methods is as far off as ever. The first station in New York was that which was started by the Edison Company in 1882; and it is natural that the demand has increased to such an extent that it can no longer supply the needs of the district. Other stations have since been erected, and the oldest one, which was burned down something like a year ago, is now about to be replaced by an entirely new and fully equipped station in Elm-street. It is necessary to bear in mind, in examining an American supply station, that the designers seldom if ever work with a free hand. Unlike an English engineer, his American *confrère* cannot order his dynamos from one or several makers, his steam engines from another, and so on; he has to use the materials which go to form the "system" in vogue with his company. The details may change gradually, as one chief engineer succeeds another; but there does not seem to be much demand for careful design and planning as we understand it.

Digitized by Google

The Edison Company has, however, made a new departure and the style of station, first inaugurated, if we remember rightly, in Philadelphia, is likely to become stereotyped as part of the "system," and future stations of this company will probably be repetitions on different scales of the new pattern. The work on the new station does not seem to have arrived at a very advanced stage, and it does not even appear from the technical papers that the type of dynamo to be used has been definitely decided upon. "The company," says the *Electrical Engineer* of New York, "favours a series-wound disc dynamo, and the indications are that such a type of machine will be used." The engines alone have been decided upon, and these are to be of the Van Vleck quadruple-expansion "disconnective" inverted type. Six or eight engines of 4,000 to 5,000 H.P. each will be put down. Our contemporary speaks of these as "an ample number of large units," but explains this statement as relating to the effect of a breakdown of one member on the working of the station. The day load of the district is said to be peculiar, attaining a maximum between 10 and 11 a.m., and admitting of nearly 12 hours run on full output. The Van Vleck engines were described in the *Electrical World* of New York of January 23, 1892. For the purpose of preventing the complete breakdown of a large engine, in case of the disablement of one part, it is arranged to run with any of the cylinders out of gear. The steam chests are placed in front of the engines instead of between them, in order to save floor-space, but the setting of cylinders in tandem is considered objectionable. The cut-off of all three cylinders in the triple-expansion engines of this class is controlled simultaneously; and while the economy of this is doubtful, especially if the increased complication of valve gear be put against it, the engine will no doubt respond more quickly to the governors. In ordinary supply work little else than a runaway governor is wanted; and if a good governor is to be used, it should be controlled electrically. The governors of the Van Vleck engine are high speed, and act on the Joy gear hydraulically. The old-fashioned governors which pull mechanically on a link, as on the engines at the generating station of the City and South London Railway, or the engine driving the Kapp dynamo at the Crystal Palace, can never compete with a relay governor which has merely to determine the application of a pull on the valve gear. Among other details which seem to many mechanical engineers a confession of weakness and not a precaution, and which owe their introduction to the electro-mechanical engineer, if we may use the not altogether flattering expression, is the provision on this engine of water-jacketed main bearings and guide surfaces. Is metal so dear, and tooling so expensive, and floor space so valuable that decent surfaces cannot be provided? Many engineers, who have been trained in the sound and steady lines of mechanical construction, never saw a babbited bearing until comparatively recently, unless in marine or railway work; and we have never yet heard any advocate for the system who did not bring in the question of cheapness. Many English dynamo makers, and we believe we are right in saying the majority of first-class engine makers, in speaking of a "brass" mean an honest gun-metal or phosphor bronze casting, and not a hollow shell run in with something like solder, which is dignified by the name of anti-friction metal.

Quadruple expansion, of course, implies high pressure, but the type of boiler for the new station has not yet been chosen. The first-class marine boiler, says the *Electrical Engineer* of New York, "of course, cannot be used on the score of safety," though the "of course" is not at all clear, seeing that multiple expansions were first introduced and have been chiefly employed in marine work. We can quite understand that our American friends have been so overrun, or shall we say infatuated, with water-tube boilers that the art of building shells and fire boxes may have become nearly forgotten in the United States; but the advisers of the Edison Company, we are now told, "are of opinion that better results can be obtained in the matter of evaporative power than can be obtained with the present type of water-tube boiler." The inhabitants of Elm-street might object to the rivetting up of shell boilers for 40,000 H.P. on the new premises; and if, on the other hand, they are supplied ready made, the makers will no doubt be requested to "deliver and fix," and will note that the boilers are to be set on a floor about 75 feet above the level of the street. But novelties do not cease here; they do not even really begin until we learn that, suggested perhaps by the marine type of engine and possibly of boiler also, a forced draught is to be provided, with a closed stokehole, and above the boilers will be "hot tanks" or rooms. "The air, on rising, accumulates all the radiant heat from the engine, piping, boilers, &c., and in the hot rooms above will attain a temperature of 100 to 150 degrees. From these hot rooms again the air will be exhausted and sent through heaters in the stack, where it will be further heated up to 300 to 350 degrees. From these heaters it will find its way to the ash-pit of the boilers, the whole forming what is now called the hot-blast system, which has been very successfully applied on many English steamers, and is now being introduced on American vessels." What the practice on board "many English steamers" has got to do with central-station work, except that space is valuable, and that in this case the load is steady, we fail to see; and, failing to see, we will keep a discreet silence. But when we come to the announcement that Mr. Van Vleck has devoted considerable study to the construction of the steam piping which will be on what is known as his "Cannon System," we find that this is little else than the ingenious method which has been designed by Mr. Ferranti, and used at Deptford, his attention having been directed to it by the fatal explosion of a steam pipe at that station.

So far for the heavy work. But ingenuity and overthrow of old-fashioned ideas are to be found in the electrical instruments which are to be used at this station. We read of a row of ampere meters with black dots for pointers, moving in vertical slots and ranging themselves "automatically to form a curve on the side wall, showing the distribution of the load on the entire system. . . . The pressure at the ends of the feeders will also be shown in a similar manner, and will form a straight line when the pressure is normal all over the system." Main ampere meters for 200,000 amperes and voltmeters by White of Glasgow, with dials two feet in diameter,—which by the bye might well be provided in all stations—sink into insignificance. How much of all this is fad? What is it going to cost? How much will it save? Are these things improvements?

These and other questions will be asked by American engineers, and the station will doubtless be watched with interest by them. But what does this mean for us? How much longer are American and English electrical engineers to walk in their different paths? They will occasionally stumble independently on the same device, as in the case of this multiple steam pipe; they will try some so-called improvement, like the water-tube boiler, or the pasted battery plate, and will use it until the original type, which was discarded while in a still immature state, has been improved in detail while retaining the principle. It would be mutually beneficial if the electrical engineers of the two nations would assist each other; but it seems that this is not to be the case at present.

NOTES ON SUBMARINE CABLE WORK.

BY H. D. WILKINSON.

(*Continued from page 458.*)

The centipede grapnel is shown in Fig. 12. One form of this grapnel with renewable prongs is Cole's centipede. The prongs are of cast steel, two prongs being in one casting of the shape shown in Fig. 12A, and bolted to the shank of the grapnel. Trailers (as in Fig. 16) are used sometimes with the grapnels, being dragged either after or before the grapnel, to keep it

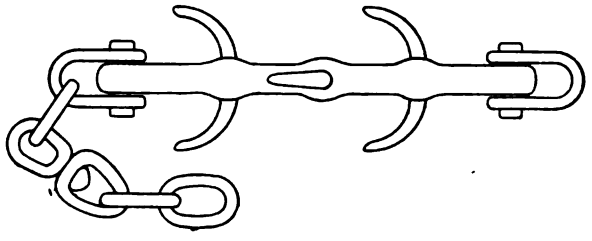

FIG. 12.—Centipede Grapnel.

from jumping, and at the same time offer a better chance of hooking the cable. There is generally also a trailing or steering chain attached to the end of the grapnel. This is a fathom or two in length, and has at one end a large link, so as to allow the other end to be rove through it after being rove through the end link of the grapnel. The noose is then hauled

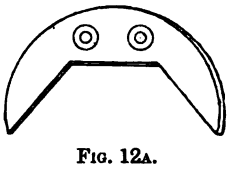

FIG. 12A.

tight, and the chain follows the grapnel, and keeps it moving in a straight line.

The forward end of the grapnel has usually about 15 fathoms of $\frac{7}{8}$in. chain attached to it to keep the front end low as it is dragged along. To the end of this chain is shackled the grapnel rope, which is usually a manilla rope, 6$\frac{1}{2}$in. cir-

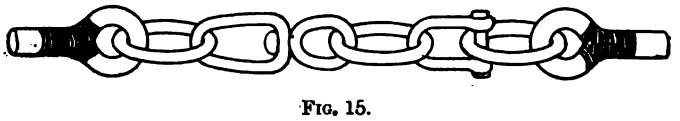

FIG. 15.

cumference, with a breaking strain of about 11 tons. A length of a few hundred fathoms of compound grapnel rope made of six cable strands of hemp yarns, with three steel wires in each, known as six-by-three rope, is generally shackled on between the chain and manilla to bear the chafing against the bottom; and this rope, for some distance near the chain, is covered with

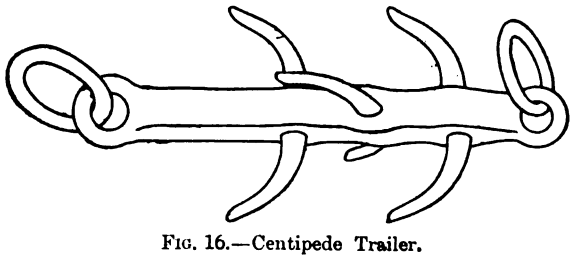

FIG. 16.—Centipede Trailer.

old matting, pieces of yarn or old rope lashed on to it in order to form a series of raised places in the rope, which will drag along the bottom, and prevent the cable from grazing along it, and so wearing away. The ends of each length of grapnel rope have thimbles and links, and one end always has a swivel and link in addition; and in coupling two lengths of rope together, one end with the swivel and link is used, and the shackle put through the two end links, as shown in Fig. 15. The swivel between each length then allows for twisting of the rope without liability to kink.

4. Special Grapnels.—When working in great depths the strain on the deep-sea type of cable is frequently the cause of its parting. To obviate this, grapnels have been devised which, simultaneously with hooking the cable, will cut it and hold the desired end. This, of course, entails grappling again, unless near a total break, but it is a more certain way to go to work, and time-saving in the long run. One of these forms of cutting and holding grapnel, designed by Mr. F. R. Lucas, of the Telegraph

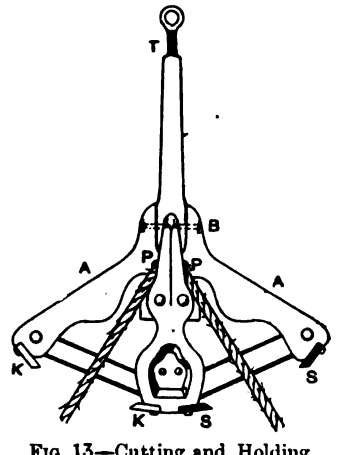

FIG. 13—Cutting and Holding Grapnel.

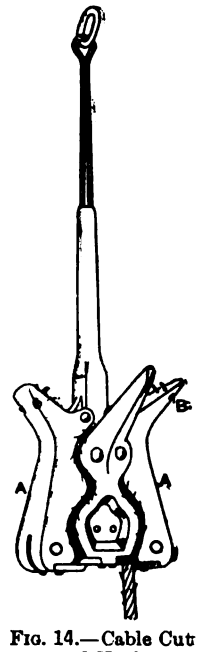

FIG. 14.—Cable Cut and Held.

Construction and Maintenance Company, is shown in Fig. 13. Two arms AA, pivoted on the pins PP, are held extended by two bolts, one of which is shown at B in the figure. These bolts are thinned down at the centre in the manner shown. The further ends of the arms carry pulleys round which a steel wire rope passes as shown, the ends of the rope passing upwards through the shank of the grapnel, where they are lashed together and form the thimble at T by which the grapnel is hauled. There are two prongs, one each side of the grapnel, and one of which is shown in the figure. On hooking the cable, the strain on the steel rope at T causes the extremities of the arms A A to bear inwards with a force which causes the bolts at B to snap off at the thin central part. The moment the bolts snap the full force of the strain is brought to bear in closing the jaws, and the bight of the cable is jammed in between the curved portions of the arms and the central stem, as shown in Fig. 14.

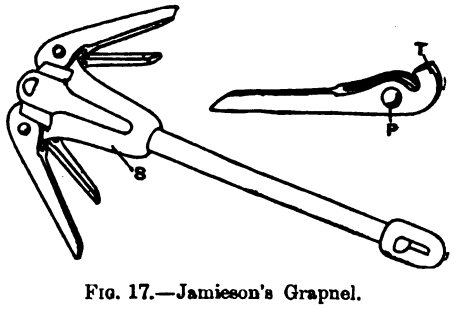

FIG. 17.—Jamieson's Grapnel.

As the jaws close, one pair of cutting edges, as at K K, close across the cable on one side, and the rapidity and force of closing cuts the cable clean through, leaving the other end firmly gripped in the jaws. The pair of knife edges shown at K K are on the near side, and would cut the left-hand side of a cable hooked on the near prong, as shown in the figure. The pair of edges S S are on the far side, and would only cut a cable caught by the far prong. In grappling it is, of course, only

Digitized by Google

the lower prong that hooks the cable, and supposing we are looking down upon this grapnel as it is being hauled along, the underneath prong will hook the cable, and the pair of edges S S will cut the cable on the right-hand side. If, now, the grapnel should roll over a rock and turn upside down, the cable, when hooked, would still be cut on the right-hand side, as the pair of edges K K are now on that side. So long, therefore, as the grapnel is hauled in one direction with reference to the line of cable, it will always cut the cable on the side desired, no matter whether it rolls over or not, and will bring up the right end. But if the direction of grappling is reversed, the knives must be unbolted and shifted to the opposite side, in order to cut the cable on the desired side. This grapnel, which has only recently been introduced, was used on the repairs of the Lisbon-Madeira cable, which it recently cut and brought up from a depth of 1,500 fathoms. Jamieson's grapnel (Fig. 17) is designed to prevent breakage of the prongs through coming in contact with rocks. For this purpose the prongs are mounted on pins as at P, about which the prong is capable of movement. The inner end of the prong has a tongue as at T, which bears upwards against a volute spring contained in the enlarged part of the shank at S. When strained against rocks, therefore, the prongs give outwards, and as soon as the obstacle is passed the internal spring acts on the tongue and restores the prong to its position again. When the cable is hooked the prongs do not give way, because the cable lays opposite the pivot of the prong, or so close to it that no leverage is exerted. Trott and Kingsford's indicating grapnel is designed to give notice by completing the circuit of an electric bell or indicator on board immediately the cable is hooked. The weight of the cable, as it lays in the grapnel, causes a brass piston or plunger at the root of the prong to be pressed down, and an electrical contact made at the grapnel, which completes the indicator circuit through the grapnel rope. The plungers are pointed below, and when weighted by the cable force their way through a rubber disc on to a brass contact plate. The grapnel rope containing the electrical core for use with this grapnel is patented by Messrs. Trott and Hamilton, and the system is used with the Anderson and Kennelly patent indicator.

(To be continued.)

THE SMYTHE AND PAYNE FIREPROOF SYSTEM OF CONDUCTORS.

Concentric wiring systems have not unfrequently been looked upon as affording an opportunity of using insulating material which would be otherwise unsuitable either on account of mechanical or waterproof qualities. In the present example there is no mystery about the insulator; it is simply glazed earthenware, and is imperishable, and practically fireproof. The system is not at present adapted for general wiring of houses, &c., but offers considerable advantages for large halls, museums, picture galleries, libraries, banks, shops, and restaurants, while its application for churches may be seen in the ecclesiastical display of Messrs. Benham and Froud at the Crystal Palace.

The inner conductor consists of stout copper wire or rod, and the outer of split tube, made of copper strip drawn through a die. Hexagonal insulators of glazed earthenware are threaded on

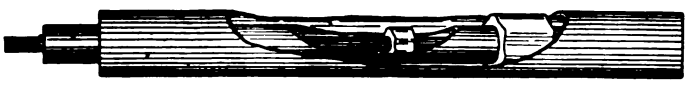

FIG. 1.

the inner conductor, and are kept in place by the spring of the split tube. [Air insulation is really employed, since the insulators are spaced about 18in. apart. An outer tube of brass or brass-cased iron, or plain iron pipe painted to suit the walls, is generally provided, and is kept from the outer conductor by larger rings of earthenware. The tube used for curtain poles is suitable for this purpose. The conductors thus arranged (Fig. 1) are made in lengths up to 18ft.; but as a rule, the whole work is measured up, and suitable lengths are prepared in the workshop ready for erection.

A number of different patterns of junction boxes and supports have been designed, and one of these is shown in the accompanying illustration. A brass box, built up of separate sides, is generally employed, plain or perforated sides being

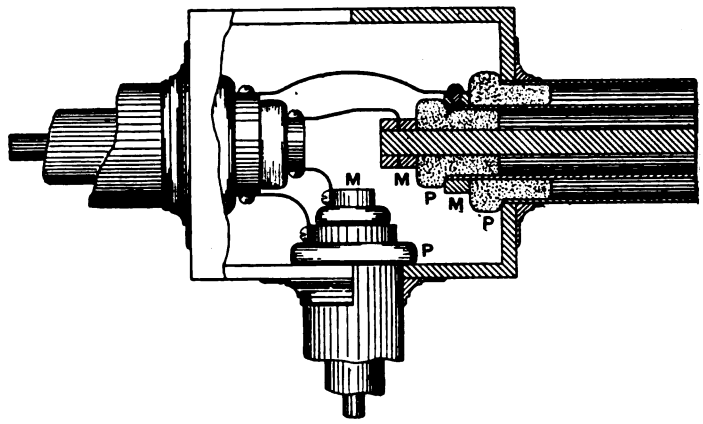

FIG. 2.—T joint of patent Fireproof Conductor. M, metal conductor; P, porcelain insulators.

provided, and fuses or switches may be mounted on them. The latest form of box has three legs to connect the top with the bottom instead of four corner pieces, allowing the conductors to be lifted out sideways without longitudinal movement. The connections shown in the illustration are made with strip or wire screwed to the conductors, but soldered sleeves are used for large tubes, and eyelets are employed for connecting thin strips, solder being applied afterwards. To avoid a general earthing of the outer conductor in event of a contact between it and the protecting tube, the latter may be divided into sections by the use of suitable earthenware insulators. The junction-boxes are readily interchangeable, and by suitable side plates may be used for simple junctions, T or double T joints, pendants, standards, or corner joints. The conductors are kept well away from wood-work, and no joiners' work or taping or ordinary insulating materials are required. The joints are always accessible, and wood casing is of course dispensed with altogether. Any leak must be a dead contact, and will therefore melt the fuse, unless an accumulation of dust and damp were to take place inside the tubes; but even in this unlikely case no fire could take place. This system offers the advantage that one class of labour is employed throughout, and the delays caused by wiremen waiting for carpenters, or the bad work which results when carpenters have to follow the wiremen, is avoided. The system readily lends itself to the construction of rows of lamps at intervals along a tube, the lampholders being fixed and connected to the conductors. Such rows would be very convenient for the lighting of shop windows, and a plain pattern with iron casing tube would be very useful for theatre work.

OIL AS AN INSULATOR.*

BY PROF. D. E. HUGHES, F.R.S., PAST PRESIDENT.

At our last meeting, Mr. Preece kindly gave me credit for being the first to propose the use of oil as an insulator for wires conveying an electric current; and in accordance with a suggestion on his part, I should like to state upon what grounds I can fairly be considered to be the first to urge upon the electrical world the use of hydro-carbon oils, such as petroleum and resin oil, for this purpose.

In 1858 universal regret was felt on the failure of the insulation of the first Atlantic cable. From the first successful laying of this cable the insulation gradually became worse, until in a few days all signals failed. The cause of this was supposed to be due to minute flaws in the gutta-percha during its manufacture, which became worse by submersion, or that lightning, or the intense currents

* Paper read before the Institution of Electrical Engineers, Thursday, March 10, 1892.

Digitized by Google

then used for the Whitehouse induction coil, punctured the cable at several points. It appeared to me (from some old experiments of mine) that what we needed was some form of insulation that possessed self-restoring powers, so that, if punctured by lightning, or our ordinary working currents, the puncture should be closed by some simpler process than having to take up a portion of the cable. I thought that Nature showed us the way in which she restores punctures and mechanical injuries to all living objects. This is done by a flow of liquid sap in plants, or blood in animals; for if we make an incision in the bark of a tree, the sap flows out and hardens in contact with air; if we cut our fingers, blood flows out and heals the wound. Therefore I thought that if I could enclose in a cable an insulating self-restoring medium, the cable would not become dead at the first, or even after innumerable punctures To carry out this object it seemed to me that a thick insulating oil, enclosed between the wire and its outer skin, would perfectly fulfil the conditions required. Faraday had shown some years previously that oil of turpentine had a high insulating property; and this gave me great hopes that I should find, by experimenting with numerous samples of oil, the kind and quality desired for my purpose. Therefore I at once commenced a long series of experiments in order to find the best kind of oil and the most suitable form of cable to carry out this idea.

Knowing that I could not fairly test these oils, or a short length of cable, by our ordinary voltaic currents, I had recourse to the very high potential currents given by the ordinary frictional static electric machine. The method used was this: I charged a battery of Leyden jars to a known degree, which was indicated upon the Leyden jars by a Peltier electrometer; these jars, when charged, were put in communication with the short piece of the cable to be tested, the outside of which was coated with tinfoil, or placed in water connected with earth and the exterior of Leyden jars. By this means, if the insulation of the few inches of cable was bad, the Leyden jars would instantly be discharged through the defective insulation; but if the insulation was comparatively perfect, the time of discharge of the electrometer was a correct measure of its insulating properties. Of course, this method required that the Leyden jars should be perfectly insulated and hold their full charge for at least one hour when not discharging through a defective cable.

On making preliminary experiments on several samples of gutta-percha and india-rubber coated wires, I found a marked difference in each variety; but as these differences were of a constant character for each sample, it was easy to tell which of these had the highest insulating property.

These experiments showed me that if I wished to arrive at the true value of an insulating oil, I must make the experiments by a method by which the results should be entirely free from any interior or exterior coating. For this I took two small flat circular discs, 1in. in diameter, which could be immersed in oil, and by an insulated adjustable screw I could compare the striking distance of these discs in air, compared with the same when immersed in oil, and could also observe the time required for a complete discharge of the Leyden jars through this medium.

On testing numerous samples of different oils, I found not only a great difference in the species of oil, but also a great difference in different samples of the same oil; consequently a table giving the results on different oils might be misleading, as a sample of superior quality of a certain oil (although inferior in many other samples) might give higher results than a badly selected sample of a really superior oil.

The only difficulty as regards resin oil is one of manufacture, or, rather, of finding, and teaching the makers, the quality of oil best suited for the purpose; for I found, on obtaining samples of this oil from different makers, that a great difference existed as regards their insulating properties, ranging from worse than castor oil up to a degree superior to gutta-percha; and this is true of most oils; consequently, before using any oil, its quality as an insulator should be thoroughly known by constant electrical tests.

In selecting oil of high insulating quality, we must also have regard to the purpose for which it is to be used. Thus, as a self-restoring medium having very quick action, for condensers, transformers, or coils so closely wound as to be difficult for a thick oil to penetrate, a thin resin oil, such as resin spirit, might be best; but for cables and underground wires I found thick pure resin oil best, because it was not only superior as an insulator, but it would not escape too rapidly at any large puncture.

Experiments were also carried on at the same time to observe the effect of any given oil on thin sheets of gutta-percha, india-rubber, &c. These were immersed in separate vases of different oils: they were weighed before and after prolonged immersion; the result being that some oils were found to be injurious to gutta-percha, and almost all, with the exception of castor-oil, were more or less destructive to india-rubber.

I found, after numerous experiments, that pure resin oil gave the highest insulation of all, for a spark that would pierce a given thickness of gutta-percha would utterly fail to pierce the same thickness of resin oil; whilst, if the gutta-percha was pierced, its insulation was destroyed and could not be easily restored to its former condition; on the other hand, if by accident the resin oil was pierced, it, by its own mobility, at once restored the insulation to its original state. Resin oil, at the same time, had a preservative effect upon gutta-percha, for the sheets immersed in this oil had become slightly increased in weight, showing that it had penetrated into the pores of the gutta-percha; at the same time it was stiffer and tougher than before immersion. I will now show you an actual specimen of this fluid cable, cut off from a specimen one mile in length, made by the Gutta-Percha Company 33 years since. You will observe that the gutta-percha has absorbed, during that time, a large proportion of the oil, and that the gutta-percha is now, after 33 years' exposure to the air, apparently as good an insulator as whenfirst made.

Experiments were now made as to the value of resin oil when employed as the sole insulator of an electric cable. For this purpose, a short length of copper wire (say 1ft.) was coated, first, by being wound by well-dried cotton or hemp, or, better still, by a string wound round in wide open spirals, in order that the oil should penetrate as freely everywhere as possible; this was afterwards drawn into a small lead tube filled with resin oil; thus the string or fibrous covering on the wire was simply to keep the wire concentric, so as to prevent its touching any part of the exterior tube without some separation of oil or oil-saturated fibre. It will be seen that these tests were identical, both as to form and material, in their essential points, with those patented by Mr. David Brooks, of Philadelphia, some 15 years later; but as these are clearly described in my patent of January 11, 1859, there can be no question of priority in this respect, though no doubt many improvements suggested by practical experience in the mode of laying and manufacture are original with Mr. Brooks.

The insulation of this form of cable was not quite as high as solid gutta-percha, due to the fibre not being as good an insulator as the enclosed oil; but its mechanical powers of self-restoration and durability seemed to me to more than counterbalance its slightly less insulating power, for even with gutta-percha there are questions of strength and durability which ought never to be lost sight of in favour of a temporary high insulation; and I think that when the value of fluid insulation is more thoroughly known, especially for currents of high potential, it will be more generally used than at present, particularly as there are now no valid patent rights to interfere.

I again repeated these experiments, using a thinly covered gutta-percha wire for the inner conductor, drawn into a gutta-percha tube full of resin oil: this gave me very high insulation—so much so, that I tried a bare copper wire in the gutta-percha tube alone, without any resin oil: this, to my surprise, gave a far higher insulation than the best gutta-percha-covered wires as supplied to me by the Gutta Percha Company. This surprised me very much, as the tubes, which I bought at an ordinary retail shop, were known to be of an inferior quality of gutta-percha. I found afterwards that this difference was due to the tubes having been long made, and kept in stock: they had gradually dried, and were free from combined moisture absorbed during their manufacture. I proved this by taking some newly manufactured gutta-percha, and heating it gradually for a length of time sufficient to drive off its moisture: this, when modelled on a wire, so as to form a cable, gave precisely the same degree of high insulation as the old tubes that I had purchased elsewhere. I do not believe that the mechanical quality of the gutta-percha was improved by this operation; most likely it would have soon become brittle, for humidity, or an essential oil, seems necessary to its life and mechanical qualities.

I told Mr. Chatterton and Mr. Willoughby Smith, of the Gutta-Percha Company, of these results, and urged upon them the necessity of well drying the gutta-percha, and of manufacturing their cables, if possible, without constantly macerating it in water. I am not aware that my remarks had any effect, but this I remember, that in a few weeks after they gave me a sample, which they called "special gutta-percha," which certainly had as good insulating qualities as my dried gutta-percha.

As I have already said, my main object being to produce a self-restoring insulation for cables and underground wires, I found that a thin fluid, such as resin spirit or petroleum, might be objectionable, as at the point of fracture or puncture the fluid might escape with so great a rapidity as to be somewhat costly in its maintenance; but by employing a thick, heavy insulating oil, whose rate of flow would be small, this would displace any water in the puncture, provided that there was a slight head pressure given to the oil at a reservoir at certain landing stations; then it would answer all practicable purposes. For this I preferred resin oil, which is already a thick, viscid oil, and can be made more so by the addition of solid resin dissolved in it, or by the addition of palm oil residue, which has a remarkable property of thickening resin oil. In order to satisfy those who might object to even a very small leakage of oil at the puncture, I made several compounds of resin oil, mentioned in my patent, that should harden when in contact with water, and thus prevent any waste of oil at the fault or puncture.

Digitized by Google

The static charge which I used was of high potential; the sparking distance in the air, of the charge used, was about 1in., and it showed the remarkable insulation of resin oil when 1-64th of an inch separation would effectually prevent such a spark passing through it. After having found this high insulating property of resin oil I coated all my Leyden jars, and all parts where I desired high insulation with it, and by this means I was enabled to retain a full charge of the Leyden jars for several hours in an atmosphere full of humidity.

They have lately proved the value of oil insulation in Frankfort by the use of oil in transformers of 20,000 volts, and I am convinced that in all cases where we need a high insulation, together with the power of self-restoration, it can only be found in fluid insulators. It is useful in every case where it can be applied; it is far cheaper than gutta-percha, and I have no doubt that it will soon be used for insulation in condensers as well as transformers. Mr. Nikola Tesla, in his late charming lecture, spoke highly of the use of oil in his transformers, saying that it not only gave a perfect insulation, but had the power of restoring the insulation whenever pierced or punctured, as he believed his coils were at least several times every day.

I remarked during these experiments that, no matter how high the potential, the amount of leakage was equal in time, either with a high or low charge of the Leyden jars; that is to say, when the Leyden jars were discharging at a slow rate through a good insulator, the time of falling of the electrometer through any given number of degrees was very equal throughout its whole range from 200,000 to 1,000 volts.

Being desirous of repeating this evening some of my old experiments, I applied to Mr. W. H. Preece for some of the best samples of gutta-percha-covered wires as used by the Post Office, and which he has most willingly sent me. I also applied to Mr. James Wimshurst, the inventor of the remarkable static electric machine, who at once most kindly consented to lend the machine, and also design an arrangement by means of which we could show to those at a distance the different distances of the sparking through oil compared with air.

On testing this apparatus with oil, it seemed to show that the value of oil as an insulator increased both with the potential of the charge and also with the rapidity of alternations, for when the experiments were made by an impulsive rush so as to have the greatest number of oscillations per second—say 1,000,000—then even the poorest oil, such as castor oil, showed marked superiority over air or gutta-percha. This confirms the advantage of oil, and its value in connection with the rapid alternating high-voltage currents used in our transformers of to-day. The experiments which we hope to repeat this evening have already shown us that a spark, or charge, from a Leyden jar, which would easily pierce 4in. of air, will not pierce $\frac{1}{10}$in. of resin oil; proving that oil, when resisting an impulsive rush of a charge, has 79 times higher insulation than air.

To obtain these results, we used a large and most powerful Wimshurst machine; but this evening, for convenience sake, we shall use a smaller machine. We may not be able to obtain quite as high comparative values, still we hope to obtain results showing oil to be 50 times better an insulator than air.

With the largest machine we obtained the following remarkable effects. The apparatus for holding the oil was a glass vase 4in. in diameter by 3in. deep. The lower portion of this vase had a copper plate connected with one portion of the circuit. A brass knob, $\frac{1}{2}$in. diameter, connected with the other portion of the circuit, could be raised or lowered in this vase in order to show the different striking distances when the vase contained air or oil. This gave the comparative results already mentioned; but, in addition, we noticed that when the knob was only covered three-quarters with oil, the spark rose from the upper portion to the upper portion of the vase, and then descended on the outside in order to reach the lower copper plate—a course of some 5in. through air, compared with $\frac{1}{10}$in. through oil. If now the current was increased, the current, or spark, became a continuous sheet flowing all over the entire surface of the vase, resembling in appearance a waterfall, or exactly imitating the well-known Gassiot cascade. On again increasing the charge in an attempt to pierce the oil, the spark pierced the glass vase, making a small hole of about $\frac{1}{32}$in. diameter, at a place $\frac{1}{2}$in. above the surface of the oil: thus the spark preferred to pierce the glass and travel several inches through air, rather than traverse a distance of $\frac{1}{10}$in. through oil.

I will now show several forms of oil insulation as applicable for submarine or subterraneous wires, and the remarkable power of self-restoration when the insulation is temporarily destroyed by a puncture or cut across so as to lay the wire bare for an instant.

It will be seen in the experiments following this Paper that I have arranged a battery so that one pole is connected through a sensitive galvanometer to a metal tank containing salt water, the return circuit being completed through the salt water and wire to be tested to the other pole. If we take any sample of gutta-percha-covered wire and place it in the water, the insulation seems perfect and all that could be desired; but if we make a small incision with a knife, so as to leave a minute portion of the copper exposed, then (as we already know), on placing this in the tank, the water at once percolates through the cut to the wire, and its insulation is completely and permanently destroyed. If we try this same experiment with oil cable, such as a bare copper wire in a gutta-percha tube containing oil, or, better still as a proof, a thinly coated gutta-percha wire, and this plunged into a small lead tube containing thick resin oil, the whole having the same diameter as the gutta-percha-covered wires, we find, on testing this lead-covered oil cable, that its insulation is as perfect as the gutta-percha wires. If we now cut through the lead tube and the gutta-percha wire once or several times so as to lay the wire bare, the insulation for an instant is destroyed, but in less than a second the oil percolates through the wound or cut, and its insulation is instantly restored to its previous high value.

I believe that these experiments sufficiently show the merits of a self-restoring insulating medium, such as resin oil, for all purposes where a permanent insulation of wires conveying an electric current is desirable.

In conclusion, I will mention a few proofs of my claim to be the first to recognise the value of oil insulation for wires conveying an electric current, based upon some earlier experiments, but patented January 11, 1859, entitled, "An Improved Mode of Insulating Electrical Conducting Wires," which describes and claims most of that which I have already related. I will read a few sentences, in order to prove this fact. After showing how the oil may be applied to submarine cables, and in order to claim its application to underground wires, the specification says (p. 3, line 10): "With some trifling modifications, the invention may be also applied for insulating electrical conducting wires employed on land or underground." As regards the materials used, it says (p 4, line 23): "I propose and prefer to use resin oil, rendered sufficiently thick or viscid for the purpose by the addition of resin or the solid residuum obtained from the distillation of palm oil." In order to show that the interior wire may be covered with a fibrous material instead of gutta-percha, it says (p. 4, line 34): "Instead of bringing the soft or semi-fluid restorative medium in direct contact with the enclosed wires, I sometimes first coat the wires with a non-conducting material, such as gutta-percha or india-rubber, and, if preferred, the wire may be previously covered with some fibrous material." My invention being as well adapted for numerous wires in an underground cable as in a single-wire cable, it says (page 5, line 6): "And the invention is as applicable when two or more electrical conductors are placed in one common tube or outer covering as when only one conductor is employed."

If the patent is hurriedly read it would seem as if I only intended to use the oil in connection with gutta-percha cables; but I foresaw the use of other outer covering, such as lead or iron tubes, for it says (page 4, line 37): "The insulated electrical conductor thus coated or covered is then placed in a gutta-percha or other tube." This phrase "other tube" referred to my experiments with an outer tube of lead or other metal; and I again employ the same phrase at page 5, line 13, where it says that the wires surrounded by the resin oil "may be placed in the gutta-percha or other outer covering."

A Paper on this subject was read before the Society of Arts and published in their Journal, April 15, 1859, in which I demonstrated by practical experiments the restorative powers of my fluid insulation. Sir William Fothergill Cooke, the Chairman, in reply, spoke in praise of the results, and said he "also thought the invention would be very valuable as applied to the street wires of electric telegraphs, and these afforded more facilities for testing its value." So it cannot be said that its applicability to underground wires was not foreseen at that date.

From 1858 to 1860 I tried by every means to get the various land and submarine electric telegraph companies to try this system, but in vain. I thus lost two years of valuable time, and then went to France in connection with my printing telegraph instrument, to which I devoted my whole time for many succeeding years, thus practically abandoning my self-restoring fluid insulation to the public. The cause of its failure to be used then was due to the fact that the invention was made before its time, or that the need of its use was not then as great as at the present time. I am glad to say that now, thanks to electric light and power, the use of a self-restoring oil insulation is fast coming into actual practice under the names and patents of numerous succeeding inventors; so I sincerely thank Mr. Preece for citing my early work, and thus giving me this opportunity of claiming as priority the work that I had done before and patented in 1859.

My best thanks are due to Mr. Preece for the samples of gutta-percha wires, galvanometer, &c.; to Mr. James Wimshurst for the loan of his static electric machine, and for his great assistance in preparing some of our experiments on high-tension currents; also to Grindley and Co., of Upper North-street, Poplar, for having supplied me with numerous samples of their best oil, from which I have selected the oil that I have used this evening.

SOME EXPERIMENTAL INVESTIGATIONS OF ALTERNATE CURRENTS.*

BY ALEXANDER SIEMENS.

(*Concluded from page 464.*)

Some further experiments were made with the same alternate-current machine and transformer, and a frequency of 100 ∿ per second, to determine the striking distance in various insulating materials. The differences of potential were again measured by Sir William Thomson's static voltmeter, or, in the case of the higher ones, by his volt balance.

One series of experiments, represented by curve 18 (Diagram 7), was made by connecting the terminals of the transformer to the inner and outer conductor of concentric cables, the insulation of which consisted of impregnated fibrous material. The difference of potential was then gradually and slowly raised until the insulation gave way. Curve 18 really consists of two parts, the lower of which was obtained by breaking 35 short samples of cable, made with various thicknesses of the insulating material; the upper part, above 7,000 volts, was determined by breaking actual cables, not less than 50 yards in length, specially manufactured for these experiments.

The next series of experiments dealt with india-rubber insulation, but results proved to be extremely irregular, although a curve (Diagram VII., No. 19) has been plotted which gives the minimum voltage at which sparking occurred at the various thicknesses.

The concentric cables were tested by connecting the transformer to the two conductors; the sheets were placed between the disc and the spherical electrode. The core, when in short lengths, was covered with tinfoil; when long, it was immersed in water; and the terminals of the transformer were connected, the one to the insulated conductor, the other to the water or the tinfoil respectively.

Another set of tests was made by placing calico on the disc of the spark micrometer, and by connecting the other pole to a copper brush, such as are used in dynamo machines, resting on the calico.

Several samples of calico were tried—

(*a*) Thin calico, 0·12mm. thick, not impregnated.

(*b*) Silesia calico, 0·15mm. thick, not impregnated.

(*c*) Thick calico, 0·30mm. thick, not impregnated.

(*d*) Thick calico, 0·30mm. thick, impregnated.

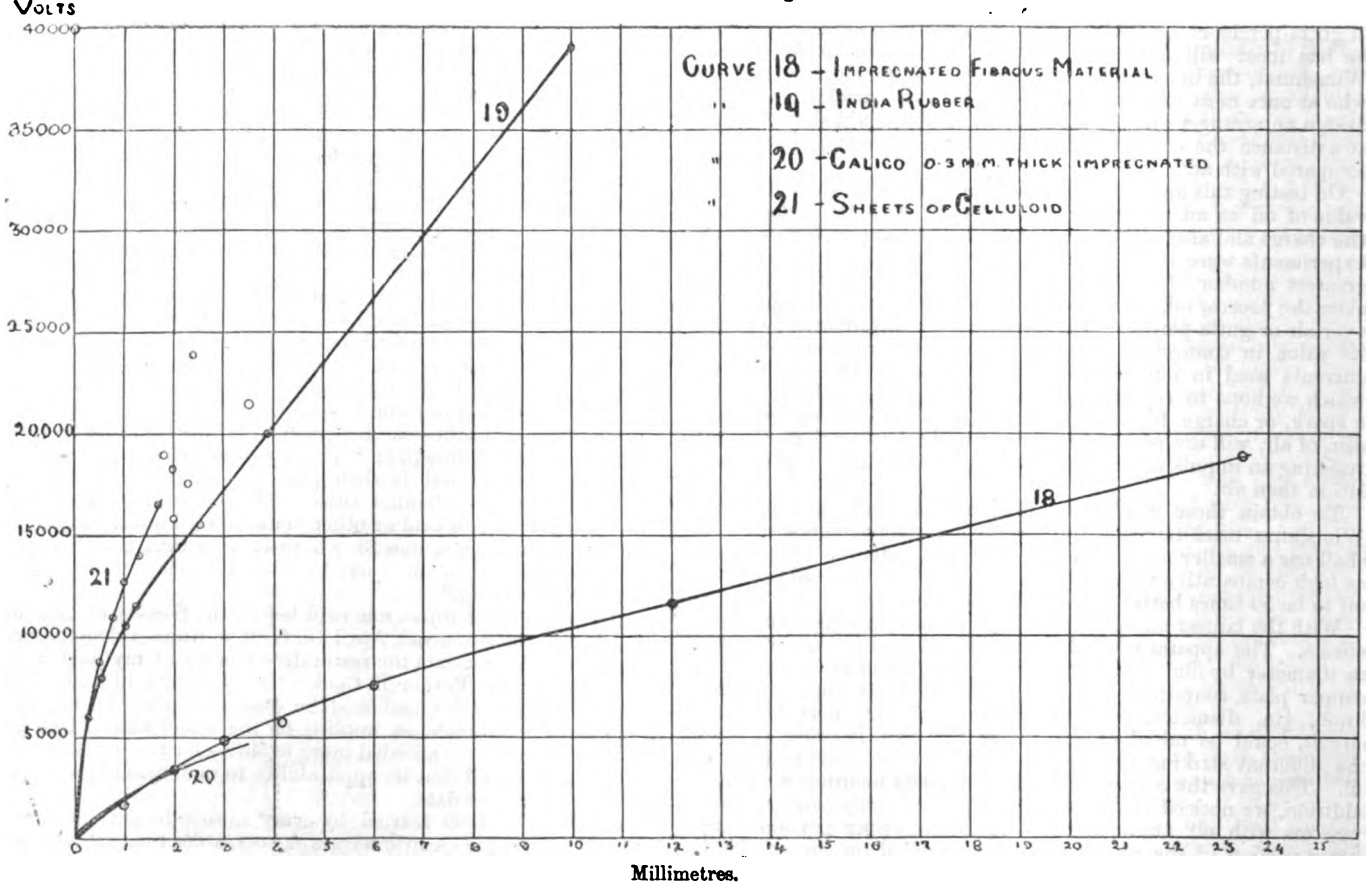
All four samples required the same lowest difference of potential —about 700 volts—for a breakdown. Different spots of the same sheet behaved very differently, some not breaking with even 1,000 volts; but at least one spot could always be found which broke down with 700 volts.

Curve 20 (Diagram VII.) gives the results obtained with several layers of the impregnated thick calico. The layers were tightly pressed together before being tested, and the points of the curve give the minimum value of the voltage which broke them down.

The last curve (Diagram VII., No. 21) records the sparking distance

DIAGRAM VII.

Sparking Distances in Insulating Materials.



through celluloid which was tested in sheets placed between the two discs of the spark micrometer.

A good many of the high-tension experiments were made with a specially constructed powerful transformer, capable of giving at its secondary terminals a current of 2 amperes under a pressure of about 50,000 volts. This is now on view at the Crystal Palace Electrical Exhibition, and various experiments are shown to exhibit its qualities. Unfortunately, it is too heavy to be shown in this Institution.

In conclusion, it should be mentioned that all the experiments described in this communication were carried out at Woolwich, at the works of Messrs. Siemens Brothers and Co., mostly under the immediate care of Dr. Baur, who was freely assisted by the heads of the various departments whenever he encounted difficulties in the course of his work.

The following table gives the details of the samples tested, and under what voltage they broke down:—

No.		Thickness of indiarubber.		
1.	40in. of 880 H wire	3·5mm.,	broke with	21,500 volts.
2.	10 yds. of experimental core ...	3·8mm.,	„	20,000 „
3.	1½ „ „ „ ...	2·5mm.,	„	16,000 „
4.	1 „ concentric cable	3·5mm.,	„	28,000 „
5.	90 „ No. 504 core.....	1·2mm.,	„	12,000 „
6.	46 „ „ 505 „	2·0mm.,	„	16,500 „
7.	50 „ „ 507 „	1·8mm.,	„	18,200 „
8.	48 „ „ 508 „	2·3mm.,	„	16,800 „
9.	5 „ „ 200 H.....	2·3mm.,	„	28,000 „
10.	1 „ concentric cable	2·0mm.,	„	17,500 „
11.	Indiarubber sheet	0·5mm.,	„	7,500 „
12.	„ „	1·0mm.,	„	10,500 „
13.	Experimental piece of core .....10·0mm.,		„	38,000 „

* Paper read Thursday, 11th February, 1892, before the Institution of Electrical Engineers.

DISCUSSION.—THURSDAY, FEBRUARY 11TH.

The PRESIDENT requested that before the discussion was commenced questions should be asked on any points of Mr. Siemens' Paper on which

Digitized by Google

further information was desired.—Mr. SWINBURNE wished to know how long the E.M.F. was applied when determining the sparking distance, and whether when measuring in air the electrodes were steadily brought nearer till the spark passed.—A MEMBER asked what rubber was tested, whether vulcanised or not.—Mr. TROTTER asked how the thickness of the insulation in the concentric cables was measured.—Prof. FORBES suggested that any discussion on Mr. Siemens' Paper should be postponed till the next meeting, when the members would have had the opportunity of seeing it in print.

THURSDAY, FEBRUARY 25TH.

Mr. SIEMENS, in answer to the preliminary questions asked at the last meeting, said with regard to the time in the breakdown tests, half the estimated breaking pressure was first applied and then raised step by step; each rise taking some 2½ minutes, and then being left on never less than a quarter of an hour, often hours or days, before again raising. Time made no difference in air spark experiments. The vulcanised rubber tested was the same as that used for insulating cables; the thickness of concentric cable insulation was measured from the outside of the inner conductor to the inside of the outer. He considered that the way of manufacture had more to do with resisting sparking through than the actual material used.

Prof. PERRY welcomed Mr. Siemens' Paper as giving actual values in transformer work, which were much wanted. He would, however, like to have much fuller details, so as to know what weight to give to the results. He rather doubted the method of measuring temperature. 1° rise meant a variation of ·002 ohm in 1·3 ohm; and, if the battery was not reversed, thermo-electric forces might exist quite commensurate in effect with this small change of R.

Dr. FLEMING objected to Mr. Siemens' calculation of the eddy currents, which he said were all 20 per cent. too low; consequently, the hysteresis loss, which was got by deducting the eddy current loss from the total loss, was too large. Mr. Siemens' results, when corrected, made the hysteresis loss exactly proportional to the induction, the loss being $\cdot 625 \times n \times B \times 10^{-7}$ watts per cubic cm. In the eddy current loss the temperature of the core must be taken into consideration, as the loss decreased ·6 per cent. per degree rise. With fine wires the loss was practically solely due to hysteresis, but with large wires or plates the eddy currents were far more important. He considered that the alleged decrease of hysteresis loss at full load might be due to the iron getting hot and the eddy currents less than were calculated.

Mr. EVERSHED said that the last source of error pointed out by Dr. Fleming roughly counteracted the first, so that the figures given were practically right. He much preferred the use of a clinical thermometer for measuring the temperature of the core, and considered it less liable to error than resistance measurement methods. Mr. Siemens apparently made no allowance for the heating of the core by the exciting current in the copper. The way he, the speaker, employed was to pass an equivalent direct current through the windings, and note the temperature of the core. In some experiments made by himself and Mr. Vignoles, the heating observed by thermometer had been some 6 per cent. greater than that accounted for by calculated eddy currents, static hysteresis, &c. This 6 per cent. he felt inclined to attribute to viscous hysteresis.

Mr. SWINBURNE did not think that the increased heating due to increase of current in the copper caused the alleged decrease of loss in the iron. Mr. Mordey was the only one who still upheld that there was such a diminution, and in Mr. Mordey's transformer the copper was inside the iron.

Discussion adjourned.

PHYSICAL SOCIETY.

At the meeting of this Society, on February 26, 1892, Prof. W. E. AYRTON, F.R.S., Past President, in the chair, Prof. S. P. THOMPSON, F.R.S., read a Paper

"On Modes of Representing Electromotive Forces and Currents in Diagrams."

The author said he had found it advantageous in some cases to depart from the usual methods of representation, and he now brought the subject before the Society in order to have it discussed and improvements suggested. To indicate the directions of currents in wires seen end-on, Mr. Swinburne had used circles with and without crosses, but no symbol had been suggested for wires not conveying currents. He (Prof. Thompson) thought the plain circle should be used for inactive wires. A circle with a dot in the middle could then be used to indicate that a current was flowing towards the observer, and a circle with a cross in it to represent a wire conveying a current away. These meanings could be recalled by considering the direction indicated by an arrow, the dot showing the tip of the arrow and the cross the feathers. Some method of distinguishing between volts and currents was required. For this he proposed to use thin-stemmed arrows with feathers for volts, and thick-stemmed ones without tails for currents. In the case of electrical transmission of energy, this convention had the important advantage that where the two arrows had the same direction, energy was being given to the system; and where the arrows were opposite, energy was leaving it. Mr. Maycock, he said, had recently published a simple rule for finding the direction of magnetic force due to a current of known direction in a wire. Grasp the wire with the right hand, the thumb pointing in the direction of the current, the fingers will encircle the wire in the direction of the magnetic force. Dr. Fleming's well-known rule for induced currents was also a *right-hand* rule: but as

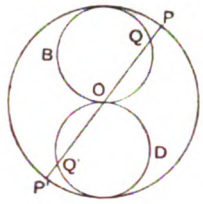


FIG. 1.

it referred to the direction of *currents*, another rule was necessary when considering motors. By making the rule refer only to volts, only one rule was required for generators and motors. For alternating currents the author found it convenient to draw polar

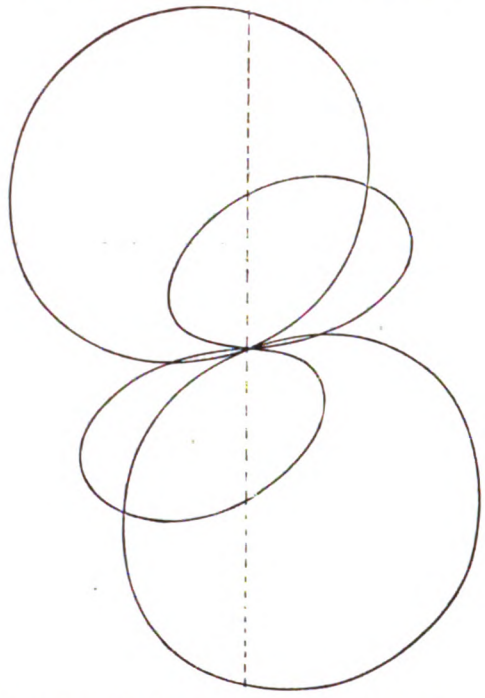

Fig. 2.—Polar curves plotted according to Prof. Thompson's method, from the curves of Profs. Ryan and Merritt. (*The Electrician*, Jan. 22, p. 296.)

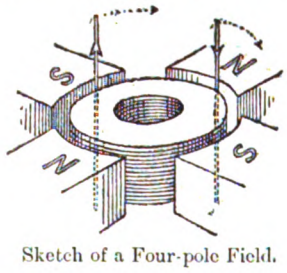
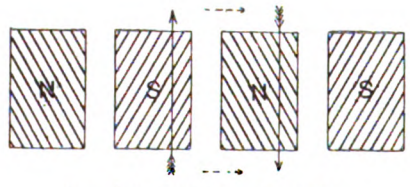
curves analogous to Zeuner's valve diagrams. Suppose a line O P, (Fig. 1), representing the maximum value of an E.M.F., or current whose magnitude is a sine function of the time, to revolve at uniform velocity about O; the intercepts O Q, O Q', &c., cut off by



Sketch of a Four-pole Field.



Four-pole Field developed flat.

FIG. 3.

circles O Q B, O Q' D, will represent the magnitudes at the times corresponding to the positions O P and O P'. The effect of lag can also be represented in such diagrams. In cases where the variables are not sine functions, the curves O Q B, and O Q' D,

Digitized by Google

are no longer circles. Polar diagrams representing the volts and current curves obtained by Prof. Ryan in his transformer experiments were exhibited, and a working diagram illustrating the changes in three-phase currents was shown. To show the directions of induced volts in diagrams of dynamos and motors, diagonal shading of the pole faces was sometimes convenient; the lines over north poles (Fig. 3) being drawn from left to right downwards *in the direction of the middle stroke of the letter* N, and those over south poles from left to right up-

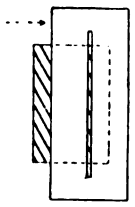


FIG. 4.—Sheet of paper, having a narrow slit cut in it, moved from left to right; the lines appear to run downwards.

wards. A conductor passing over a north pole from left to right (Fig. 4) would have an E.M.F. induced in a downward direction, as indicated by the slope of the diagonal lines. This method of representation was used to show the ways of connecting up multipolar drum armatures, the winding being supposed cut along a generating line unwrapped from the core, and laid out flat in the manner adopted by Fritsche. In connection with armatures, the author said a formula had been published, by means of which the nature of a winding, consisting of a given number of convolutions and to be used with a given number of poles, could be predetermined. This, he thought, would be very useful in practice.

Mr. BLAKESLEY said the old method of representing alternate-current magnitudes by means of the projections of revolving lines seemed preferable, for it left no ambiguity as to the directions of the quantities. The method of shading the poles also required that the direction in which the diagram was to be viewed should be known before the direction of the volt could be determined.

Mr. SWINBURNE suggested that the author might use a bow to represent volt, and an arrow for current. He was glad to see that Prof. Thompson recognised the differences in dynamos and motors, and approved of the view that mnemonic rules should refer to volt and not to current. The diagrams of drum windings would be very useful, and he hoped the author would make the subject clear to ordinary workmen in the next edition of "Dynamo-Electric Machinery."

Prof. PERRY considered it undesirable to use polar curves for anything but circles. In his opinion it was not sufficiently known that any curve can be split up into a series of sine curves and each component dealt with separately, the separate results being added together in the end.

Mr. SWINBURNE pointed out that before one could analyse a curve in this way the curve must be known, and would probably have to be determined experimentally. If means for finding one curve are available, any other required curve could probably be found by the same apparatus; hence there was no need for analysis.

Prof. PERRY remarked that experiments could not be made on a machine before the machine was built, whereas the E.M.F. curve could be predetermined from its design. By analysis its current curves when working under various conditions could be found.

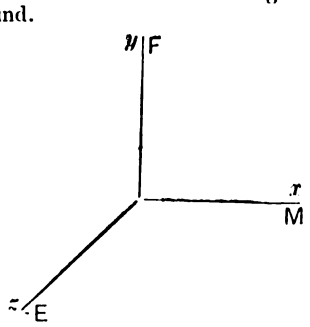

FIG. 5.

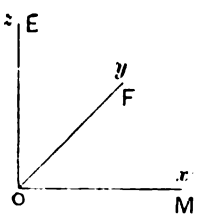

FIG. 6.

Prof. AYRTON, referring to the mnemonic character of the modes of representation described by Dr. Thompson, suggested that the symbols in the author's book should be more mnemonic. He himself was in the habit of using large letters for currents and small ones for resistance—A and a for the armature, S and s for series, and Z and z for the shunt, currents and resistances respectively, and σ and ζ for the series and shunt turns. He also found the following "electromotive force" very convenient:—Draw three rectangular axes, x, y, and z, as in Fig. 5. If then y represents the direction of the force (magnetic) O F, x that of the motion O M, then z shows the direction of the induced volts O E.

Dr. THOMPSON, in replying, said he thought Mr. Blakesley had misunderstood what had been said, for no ambiguity existed. In describing the windings of armatures, difficulty arose from want of proper names for the various elements, and in his forthcoming work suitable names had been given. To Prof. Ayrton he pointed out that in his book he (Dr. Thompson) had used mnemonic characters; for r_a, r_s, and r_m represented the resistances of armature, shunt, and series magnet coils respectively. The symbol I for current had also been recommended for adoption by the Frankfort Committee. He objected to Greek letters, except for specific quantities such as angles, specific inductive capacities, refractive indices, &c. He appreciated the simplicity of Prof. Ayrton's rule, but thought it would be better to rotate O E and O F through a right angle about O M, thus giving Fig. 6.

A Paper on "The Flexure of Long Pillars under their own Weight," by Prof. M. Fitzgerald, M.B., was read by Mr. Blakesley.

A Paper on "Choking Coils," by Prof. Perry, F.R.S., and a description of the uses of Rice's choking coils for regulating the brilliancy of incandescent lamps, by Mr. Hammer, were postponed until next meeting.

LEGAL INTELLIGENCE.

Lane Fox v. Kensington and Knightsbridge Electric Lighting Company (Limited).

MONDAY, FEBRUARY 29TH.

[Continuation of the cross-examination of Mr. Lane Fox by Sir Horace Davey.]

I think you gave a lecture, and a very important lecture, to a very important body on May 17, 1882, at the Royal United Service Institution?—Yes; I recollect it. It was a popular lecture on the future of electric lighting. It was not an exact exposition of my system, though my system was mentioned in it.

I will not read the whole of this, but there are some very interesting descriptions—at least, it interested me very much—of the difference between electricity and the electric current, and there is a very good illustration of the difference between air in motion and air at rest; and then, in the middle of the paragraph beginning "Motion of electricity or electric current can be produced in a variety of ways"—this is on page 257 of *The Electrician* of July 29—it is followed by a very clear description of the dynamo, and you can take my printed copy if you do not mind my marks. I give you the benefit of my pencil marks, which I hope you will appreciate. "It is on the external circuit," &c., &c. [*reading down to the word*] "electricity." The "earth" there, I presume, means the soil?—Yes.

Then you describe your central station, and you set up your dynamos, and then there is a paragraph beginning: "I have said the size of the mains at the central station will depend on the extent of the area over which it is proposed to distribute the current and the number of points at which it is proposed to use it in the production of light. That, however, is only true on the assumption that secondary batteries are not made use of as reservoirs of electricity, and that the current is supplied as it is wanted from the central station alone?"—Yes. I may say that accumulators meant more to me at that date than they did at the date of my patent. Their capacity as reservoirs had been very greatly increased; the manufacture of cells had become so improved that I saw the possibility of getting a very much larger reserve of power in them than I had contemplated at the time of my patent. I may say at that date the public mind was very much exercised as to the danger of the lights going out, and I laid great stress on the use of this reservoir, which I thought would relieve the public mind from its feeling of anxiety as to that danger.

In this passage which I have read does not the "earth" mean the same thing that it meant in the earlier passage, the actual earth, or, as you have asked me to call it, the soil?—It does not. I never contemplated the use of the soil at all. There are two uses to the term, one when it was in inverted commas, and there I did not speak of the actual earth or actual soil; the word "actual" preceded "earth," which makes a distinction. I spoke of "actual earth," meaning what we have agreed to call soil.

Now, this is the passage which puzzles me: "I do not mean that the pressure shall be at all points the same—that is not necessary, nor perhaps is it possible—that the pressure at any one point shall, so far as possible, be always the same." How could you get a different pressure? Did you contemplate the use of lamps of a different voltage all over the system?—I did at one time.

When you wrote this lecture?—Yes; I thought certain parts of the district might have a higher pressure than the other parts of the district, and there was a slight difference of voltage. It was a matter of the size of the conductors.

You surely must have the same pressure as long as you have enough amperes to supply your lamps at each point, but for the resistance of the mains?—But for the resistance of the mains. I was here contemplating the possibility of certain parts of the system being, generally speaking, at a higher pressure than other parts.

And that is what you meant by constancy? That is, the pressure at the same point shall always be the same?—Yes.

And that is what you get in your patent?—I meant that, yes; though in my patent I did not contemplate, I think, any difference of potential between different parts of the mains. I thought the mains would be large

Digitized by Google

enough. I was really thinking in my patent of a small installation. I had not worked out all the various developments that a large installation would require.

"In all cases I should proposes to use the earth in some way or other, &c., &c. [*reading down to the word*] circuit." Does not the earth mean the actual earth or soil?—Yes, because the return conductor would not be insulated, and the earth would help the passage of the current. Suppose you have a metallic conductor between the two points, the fact of its not being insulated would mean that the earth would, as it were, assist the passage.

I will put it plainly. Did you not by that passage mean to suggest a return by means of the earth in the same sense and in the same manner as it was well known to electric telegraphists?—I do not mean that it was to interrupt the continuous metallic communication.

Where do you say so? In the well-known earth return in telegraphy you lead your wire down in to the soil, with an earth plate or without, and there you leave it, and do not bother yourself?—I speak of its being a good conductor.

The earth means the actual soil?—No; I make a distinction between a good conductor and the earth.

"Which is a good conductor and in contact with the earth." You tell me that means the soil?—Yes; that means uninsulated from it.

"In all cases I should propose to use the earth in some way or other as a portion of the return to the external circuit."—Quite so.

Is not the fair meaning, and the meaning which would be conveyed to any fair mind, of that passage that you proposed to use the actual soil itself—the actual earth as part of the return in a way which was well known to telegraphic engineers?—No, I was not.

Mr. JUSTICE A. L. SMITH: It does not say "at a portion," it says "as a portion."

Sir HORACE DAVEY: Yes, as a portion.

Mr. JUSTICE A. L. SMITH: You read it as if part wire and part earth, and he says any uninsulated earth to help.

Sir HORACE DAVEY: I read it as if it meant the actual soil is to be a part of the circuit.

Mr. JUSTICE A. L. SMITH: Yes, I know, and no wires through it at all.

The WITNESS: Yes; I do not mean that.

Sir HORACE DAVEY: That is what you say.—I had a certain amount of knowledge of this question, and was not likely to make a mistake of that sort.

Sir HORACE DAVEY: It was a regular insulated metallic return at Lady Conyers'?—It may have been; I am not quite certain. I should like to point out the use of metallic returns does not preclude the use of the earth so far as it assists.

Sir HORACE DAVEY: I think your lordship may take it from me in every successful installation it has been insulated returns.

Mr. JUSTICE A. L. SMITH: Do you say that?—I say the Board of Trade made a great mistake———

Mr. JUSTICE A. L. SMITH: No; do answer the question for once, and let us get on. Do you adopt that?—I dare say Sir Horace Davey is quite right.

Mr. JUSTICE A. L. SMITH: In all these installations the return has been an insulated return?—Not at all, my Lord; in a great number, especially recently, the insulation has been abandoned as quite superfluous.

Sir HORACE DAVEY: Where?—Well, there is a gentleman—I forget his name now, some electrical engineer—that advertises his system ———

I do not talk of that. I talk about something which has been done, and tell me where it is, that I may examine it.—You have had it on board ships, in a great number of ships, nearly in all cases there.

An iron ship?—Yes.

That is what you mean by an uninsulated return, a return by the iron in the vessel itself?—Yes, they are called earth.

Do you know Lord Salisbury's installation at Hatfield? Did you ever hear there they tried the plan of attaching the return wires to the iron pipe which supplies Hatfield House with water from the spring, and that they were obliged to abandon it in a very short time after several attempts on account of the corrosion of the water in the pipe?—No, I did not hear that. It depends entirely on how the connections were made.

You gave a lecture on April 14, 1881, at the Institution of Civil Engineers, but I do not find you make the slightest allusion to any of the secondary batteries by which you keep the electromotive force in the mains constant?—That lecture was got up in a great hurry. I admitted not having yet had the time to manufacture batteries myself, so that I should not give any particulars about them. I was unable to exhibit anything working, and these people I had to deal with were people who believed in nothing unless they could see it.

Do you remember very shortly after your patent was published writing a letter to *The Times*? Well, there, having pointed out the advantage, and indeed the necessity, of a constant electromotive force, you suggest some means other than the secondary batteries?—I made a slip in the use of the word "condenser."

Just one word about the infringement. You told my learned friend that you had had an opportunity of inspecting our Kensington Works. We employ dynamos for charging the secondary batteries, and other dynamos which have no connection with secondary batteries but work directly on the lights?—No, all your dynamos are connected with the secondary batteries and the system. You label some of them "charging batteries," and you label others "line dynamos," but there is no real distinction between them.

Tell me one dynamo that in 1878 was not series wound.—The one I was most familiar with was the Gramme dynamo with permanent magnets. I also made use of a separately-excited Ladd dynamo.

Our accumulators—our secondary batteries—are at the station, are they not?—Some of them are—yes.

All of them, sir?—No,

Do you know that the battery at Queen's Gate is charged by a dynamo of its own, with its own leads, and not to the main?—I should call the lead which charged it the main. It is a mere matter of detail. It is electrically connected with the mains that supply. I have not seen the connections written down. They would not let me have their connections. Absolutely refused.

Who refused?—The solicitors of the defendant company.

There are no batteries—with the exception of Queen's Gate, if that be an exception—"dotted about the system" as you suggest?—Not dotted about, but there are batteries at two important points. At Queen's Gate and at South Kensington. There is another central station at Knightsbridge.

In connection with the same system?—I believe they have means of connecting it up if they choose.

Why do you say so?—Because I say the mains are shown in the drawing I have seen in the technical papers. I have no knowledge that I can speak of with authority.

Very well, then. Then, so far as you know—I will take the South Kensington Station—there are no stations electrically connected except South Kensington and the single battery at Queen's Gate?—That is so, I believe.

Now, about the return. Is there a return by the actual soil?—No. Oh, there is where the insulator leaks.

Do you mean to say that the defendants deliberately leave a leak?—No, I do not.

You know nothing about whether the leaks of the South Kensington returns are repaired or not?—I have had conversations with their officers, and they told me that when the leaks had got beyond a certain point they used to put them right. I think they made a great mistake in having insulation for their return conductors at all.

I understand they disagree with you, and the Board of Trade disagrees with you?—No. The Board of Trade now finds that it has made a mistake.

Mr. MOULTON: The letter has been found, Sir Horace [*handing it to the learned counsel*].

Mr. JUSTICE A. L. SMITH: What is the date of it?

Sir HORACE DAVEY: It is dated February 8, 1892. It is from my clients:—"We venture to remind you that at the inspection you made recently you were shown exactly what your expert witnesses were shown on the previous occasion, and we did not understand that on the former occasion any suggestion was made that the inspection was insufficient. We are sorry that we have now found that our first idea—viz., to give you copies of the diagrams we have prepared for the purposes of our brief—cannot be carried out; but you must please take our decision on this point as final."

Re-examined by Mr. MOULTON: First of all, my Lord, I put in the letter that was written by our solicitors, to which the one that Sir Horace Davey read was an answer. It is February 6, 1892: "Dear Sirs,—We regret to hear from our clerk that you still decline to make us copies of the diagrams showing the defendants' works. You will remember that when we had the inspection at your clients' premises on Tuesday last we stated—and it was apparent to all who were present at the inspection, including your experts—that we and our scientific witnesses could obtain no knowledge of what actually went on at your clients' works without an inspection of the underground mains. It then appeared that your clients had diagrams which you said you were prepared to show us. In consequence of this we did not further inspect your clients' premises. Now, as you refuse to let us see these diagrams, we can only conclude that your clients are endeavouring to conceal something of what goes on at their premises. Under these circumstances our counsel will probably think it right, on the case being called on, to make an application to the judge to allow a minute inspection of all the underground mains, &c."

A copy of the *Engineer* of December 26, 1890, was produced; but Sir H. DAVEY objected to its use as evidence in re-examination.

Mr. MOULTON: From what you could see at these works, does the regulating action, which you have referred to, take place?—It does, yes.

The whole action of and reason for switching cells in and out was then minutely gone into.

Mr. JUSTICE A. L. SMITH: I understood that a very few days after you got your patent you took out a patent with this switching in and out in it?—Yes; there was something more there. I proposed that instead of cutting them right out they should be joined up with the others, with a similar quantity, so as to make a larger battery of them.

Mr. MOULTON: Now I want to take you to the history of this matter somewhat. At the time of your specification to which this action relates, to the best of your knowledge, had there been any description of a distribution by the parallel arc method?—None whatever.

In the defendants' system is there anything added to those elements while it is actually working?—Nothing.

After a long cross-examination on miscellaneous points, which disclosed nothing of historical interest, Mr. MOULTON said: For the purposes of regulation is "gassing" necessary?—Not the least.

But whether batteries have been bubbled or not, does that prevent their regulating action when they are once placed in the position you indicate?—No, not in the least.

TUESDAY, MARCH 1ST.

Mr. LANE FOX was briefly re-examined on a few points on Clark and Achard's patents.

Prof. SILVANUS P. THOMPSON, being then examined by Mr. MOULTON, said that he made the acquaintance of M. Planté in 1878. Up to 1878 there were no means known by which they could get light by electricity without wavering. He knew nothing in any way prior to this specification which anticipated the patent. It was an absolute revelation. The idea of mains kept at a constant potential was

Digitized by Google

certainly new at that time. Regulating the pressure by batteries between the mains and the earth was entirely new. The lamp had not altered in character. It was still a lamp coming exactly under the description given in the first page of Mr. Lane Fox's specification.. With regard to the suggestion that the 100 volts which Mr. Lane Fox contemplates was anticipated by a statement in Staite's patent in 1847, he said that 100 cells would give anything between 190 and 36 volts.

Mr. JUSTICE A. L. SMITH: Why so?—Because, my lord, ordinary cells differ so much in their voltage. Grove cells, for example, have a voltage of 1·9 each, which equals 190 for the 100 of them, and Smee's cells have a variable voltage from about ·7 down to ·36 of a volt, or would vary from 70 to 36 volts if you take 100 of them. And both those were well known. Daniell cells were equally common.

Mr. MOULTON: Now, could this be intended to work at 100 volts?—Certainly not.

Why?—Because it works an arc lamp, and an arc lamp works at 40 to 45 volts. Staite was the inventor of the mechanism of the arc lamp.

On the question of the meaning of the term "earth," WITNESS referred to Cully's "Handbook of Practical Telegraphy," dated 1878, pages 58, 60, 61, 93, 226. "It is considered by some that the earth completes the circuit precisely in the same manner as the return wire." Then page 60, section 118: "It is better to use both the gas and water pipes for earth, so that if one be under repair the other shall still complete the circuit." "It sometimes happens that an earth cannot be found in places where there is but a thin layer of soil covering rock, or where the soil is dry." Then further down, on page 61: "All difficulty is overcome by using the iron sheath of the cable itself as an earth." The witness then briefly described the construction of a submarine cable, and referred to Mr. Sprague's "Electricity," which he said was a very well-known book, particularly for electroplaters and amateurs. At page 33, speaking of an assumption about fluid electricities, the author said: "This assumption is attended with many difficulties, all of which the molecular theory disposes of by doing away altogether with the supposed functions of the earth, which really acts simply as any other conductor does in dynamic electricity, and has nothing at all to do with static electricity. The earth connection is, in fact, nothing but a junction common to all the circuits which may be connected to it. It should be regarded as a zero or common binding screw." After other references, witness said that he had on his lecture table, in 1878, two wires, to which he could connect his apparatus for experiments. One of those wires was called "line," and the other was called "earth."

Mr. JUSTICE A. L. SMITH: Were they both insulated wires?—They were both wires stapled into the dry wood of the table, and so far insulated.

The WITNESS was then examined on the use of batteries in a supply station, and said that it was a common thing to have 55 cells, and that the battery might work with only 48. Sir H. DAVEY remarked that the defendants used 40 to produce 100 volts. The WITNESS continued, that whatever number were working at the moment the regulating action was still there, it was inherent from the very circumstance that the battery was across the mains. On Achard's patent witness said that his aim was to produce a very intense momentary current for the purpose of actuating his electric brakes. The specification would not in any way guide persons to use these batteries for any purpose of regulating. In his opinion the defendant used the system described in Lane Fox's specifications and claim. Any set of cells, whether large or small, placed across the mains from line to earth, must have a more or less equalising effect, just as truly as any fly-wheel put on an engine will tend to equalise the speed of that engine. He thought they would certainly put the middle wire to earth if they were allowed by the Board of Trade.

In reply to Sir HORACE DAVEY, Mr. Justice A. L. SMITH thought that this was not evidence.

Reference was then made to the regulations and conditions issued by the Board of Trade. "The variations of pressure from any customer's terminals shall not, during any condition of the supply which the customer is entitled to receive, nor at any time, exceed 4 per cent. from the declared constant pressure."

With regard to the light of the lamps, WITNESS next gave some figures calculated from the statistics collected by various parties from actual installations. The table of mortality, so to speak, of lives of lamps at different voltages was now perfectly well known, and on those tables of mortality he had calculated for the particular case of 100-volt lamps.

Sir HORACE DAVEY objected to this. He understood that witness was putting in a table which he had compiled from somebody else's information.

The figures which agreed with witness's experience were these. Given a lamp which was of 10 c.p. at 100 volts, and of such a goodness of manufacture that it would last 1,000 hours continuous burning, then—

Volts.	Life.	C.-p.	Volts.	Life.	C.-p.
95	3,595	7·4	101	785	10¾
96	2,751	7·8	102	601	11·3
97	2,135	8·3	103	477	12
98	1,645	8·8	104	375	12·6
99	1,277	9·3	105	284	13·3
100	1,000	10			

The efficiency in the technical sense was higher as the voltage was raised but the life was shorter.

Cross-examined by Mr. FINLAY: Would you first take Staite's patent? You told my lord on that patent 100 cells might produce anything between 190 and 30 volts. Now let me ask you, was not the ordinary cell a Daniell cell, which yielded one volt?—Oh dear, no! not at that time.

Mr. JUSTICE A. L. SMITH: What were the different classes of cells?—My brother Grove's was one.—Smee's was the best known one up to about 1836, 1837, or 1838, and then came Daniell's cells, and Grove's cells about the same time. I am quite sure he did not intend Daniell cells to be used. The object of the patent was to define the voltage, and this was his nearest approximation to a definition.

Mr. FINLAY: Now as to the arc lamps—are they not worked at 100 volts in series commonly?—No, when they are in series you allow from 40 to 45 volts for each lamp. Arc lighting can be, but is not usually, carried on at 100. I believe it is done at Kensington.

Mr. JUSTICE A. L. SMITH: We are dealing with 50 years ago, very nearly. The question is, in 1847, whether it was worked at 100 volts. That is the point.—There were no arc lamps except this, and this was the first.

Mr. FINLAY: What materials had you for saying that that arc lamp should be worked at, say, 40 volts?—Simply because arc lamps do work at 40 volts; you cannot alter the properties of the carbon.

And also at 100?—Yes, but by special devices. As a matter of fact the lamp does not get more than 45, because when you work with 100 you choke it off. Arc lamps having carbon electrodes, whether in 1847 or 1892, work at from 40 to 45 volts.

A long examination of no less than 74 questions on the meaning of the words "the earth" followed. The witness admitted that in most of the passages in Culley this expression meant the globe of the earth.

Some questions were asked with reference to the hypothetical workman in 1878. Witness pointed out that he would not be running the engine, and that there are no instructions in the specification to the engine driver or attendant at the lamps at all.

Re-examined by Mr. MOULTON: For working an arc lamp the common thing was 50 Grove cells?—That was what I used myself for years; 40 will not work a lamp quite so well. I never heard of Daniell cells being used for an arc lamp. They can, of course, be made to do so, but certainly are not suitable.

Did you ever know of Daniell cells being used for anything like currents of 30 amperes?—Yes, only for one purpose; Sir William Thomson years ago made up some special Daniell cells in trays a yard square, which would give out currents of 30 or 40 amperes. That was for a special invention of his; they were not used for any other purpose.

As a rule with 100 cells and an arc lamp there would be 40 to 45 volts pressure in the external circuit?—The arc would determine the pressure externally.

Asked as to the meaning of the word "condenser" in Mr. Lane Fox's letter to *The Times*, in September, 1878, WITNESS said that if he, in 1878, had read this passage, and he supposed he did at the time, he should have paused mentally on that word "condenser," and said, "What does the man mean? Leyden jars, or polarisation batteries—secondary batteries." He could only have meant one or other of those things. The term "condenser" was not often applied to secondary batteries—he thought he had used it himself in 1881.

Prof. WILLIAM FLETCHER BARRETT, examined by the ATTORNEY-GENERAL, said that he had devoted much attention to the history and progress of electric lighting. It was thought impossible to keep the electromotive force in the mains constant, or the pressure at the lamp itself constant. Any system of distribution, such as Mr. Fox described, with high resistance lamps, and storage cells as regulators and reservoirs of the current, was absolutely new.

The ATTORNEY-GENERAL: Was the system involving the conditions you have just described, with the then knowledge, prior to Lane Fox, regarded as a possibility?

Sir HORACE DAVEY: I object to that question.

The ATTORNEY-GENERAL: I invite my learned friend to produce anybody who will say that they thought of this as possible.

Sir HORACE DAVEY: I will invite my friend to produce anybody who has ever put it into operation.

The ATTORNEY-GENERAL: Give me simply from the specification—no more—what as an electrician you say are one, two, three, or whatever be the number of the ingredients, of Lane Fox's system?—I find in his specification the following novel points: First, high-resistance lamps made of a continuous conductor of refractory material, the quantity of light which they give being adjusted to the extent of their luminous surface—an entirely novel point. Secondly, I find a method of distribution of the current by subdivision in parallel distribution solving the problem of what was then known as the subdivision of the electric light, usually attributed to Mr. Edison. Thirdly, I find an arrangement whereby the electromotive force of the conducting mains may be kept as nearly as possible constant by a system of several generating machines, and a number of storage cells or reservoir batteries, of large conducting surface, connected up at various points of the mains. The combination of those features for the purpose was absolutely and entirely new.

The WITNESS then described the electrical plant at his laboratory. He had a gas engine, dynamo, and Planté cells joined up as described in this specification of Mr. Fox. He used any number of lamps up to ten without any regulator or switches of any kind beyond the storage cells. It had worked admirably since 1885 or 1886, and was still working. It was a regular experiment to switch off the whole of the cells and to show the unsteadiness of the lamps, and then switch them on and show their steadiness. It was quite a common thing, before 1878, when the arc ran down to switch in one or more additional cells. Sir William Siemens, in giving evidence before a Select Committee of the House of Commons on June 13, 1879, in reply to the question whether it would not be necessary to have another wire for return current said, "No, the gas and water pipes would be excellent return conductors; and if a number of central stations were to connect with these large masses of metal under the streets, the resistance of the return circuit would really become nil, and they would not only be available, but they would be extremely economical from

Digitized by Google

an electrical point of view as return conductors." After replying to another question, the witness remarked that he thought that a great injustice had been done to Mr. Lane Fox. The system attributed to Mr. Edison of the subdivision of light was really Mr. Lane Fox's system.

Cross-examined by Sir HORACE DAVEY, Prof. BARRETT was asked how a competent electrical workman could tell what size of conducting surface to take—how many amperes to the square foot?—The very word "amperes" was not in use or known then—in 1878. He would simply know that with large generating arrangements—a large current—he must have large batteries.

If the Planté batteries are so useful and so easy to work, how do you account for the fact that Mr. Lane Fox and other gentlemen preferred to use the Sellon and Volcmar ones? How do you account for Mr. Lane Fox, who makes a display now of the advantages of the batteries, in every individual case where he put up any installation, using the Sellon and Volcmar ones?—The difficulty of forming the Planté cells at first was very considerable. It was a very tedious and tiresome process. Planté gives you full directions for it. When you have done that for days, or even weeks, together, you have a couple of cells what are called "formed." Now Faure made the remarkable discovery that you could shorten this process by putting the oxide of lead straight on the cells—instead of using plain lead to begin with, to paste on the lead to begin with. That led to an abandonment of all the troublesome processes of forming the cells. Everybody said, "We will have Faure cells;" Sir William Thomson drew attention to them over and over again as a marvellous discovery, and there was a boom (as I have heard someone say) on the subject. Then Faure cells came into the market. People tried to use them. Then they found in use that this so-called improvement, although it increased the capacity and very much shortened the time that the cells required for forming, yet was not really an improvement, because the lead tumbled off and short-circuited the batteries. Then they tried to improve it in all sorts of ways. These improvements have been tending back and back, and now they find that it is better to revert to the Planté form. That is practically what it is.

WEDNESDAY, MARCH 2ND.

Prof. BARRETT, before the cross-examination by Sir HORACE DAVEY was continued, asked to be allowed to qualify or correct an answer that he gave on the previous day. Having been asked what very large cells meant, he had replied that it obviously meant that the cells should be relatively large compared with the installation, large enough to supply a sufficient draft from the mains when the force is much used and needed. If a patentee had invented a system of heating a building by steam, and was told that he might use in large buildings heating-surfaces large enough to keep the temperature constant, an intelligent workman could carry out those directions. It would not be necessary to write a treatise on heat. It would not have been easy, if the patentee wished to use a larger conducting surface than would supply the current for him, to have indicated that by saying that it must be so many ampere hours to the square foot. In 1878, they were called "*webers*" then. The general instructions contained here would be quite sufficient for an electrical engineer to carry the installation out properly.

In the course of cross-examination, the WITNESS said that the opinion of Sir William Siemens was that the gas and water pipes, for the purpose for which he was speaking, would be good return conductors. He held the same opinion as Mr. Lane Fox did at that date.

In re-examination by Mr. MOULTON, WITNESS said that, with the exception that we now had a better mode of protection than nitrogen gas, and a better substance for the conductor than platinum-iridium, no change had, in his opinion, been made in the lamp since Lane Fox's patent.

Prof. GEORGE FORBES, examined by Mr. MOULTON, said that he had given instructions for the construction of the central station of the St. James and Pall Mall Electric Company, and had to do with the specifications for the central stations of the Metropolitan Company. He also had to select the dynamos for the House-to-House Electric Supply Company, West Brompton. Apart from the action of the Board of Trade, he did not think people would trouble to insulate their returns now. In the case of the St. James's and Pall Mall Company, which used the three-wire system, he distinctly prepared the plans for the middle wire being the cast-iron pipe containing the other two, and specified that that should be connected and quite uninsulated, in order that any assistance that the earth could give would be given, but they were stopped by the Board of Trade regulations. Mr. Ferranti also, in the mains coming from the great central station at Deptford, was anxious to leave the return conductor uninsulated, but was prevented by the Post Office. In the case of electric tramways there were many thousands of electric tramcars at work in the United States, and nearly all of them had uninsulated returns.

Cross-examined by Mr. FINLAY, WITNESS said he thought it would be a very good plan, if using switches, to have a man at each battery. A boy was not very expensive, and it was not a thing which required any great attention. He did not know that the batteries at Kensington were not connected to the mains while charging. That was new to him completely. He did not exactly know how the defendants used their batteries. He thought they were being charged at the moment that they were supplying the current to the lamps. He had very little knowledge about it. He considered secondary batteries most essential for the steadiness of the light in 1885. He did not think he could name a low-tension continuous-current central station in the country without secondary batteries. He had noticed that the lamps in the court were very unsteady; they varied 15 or 20 volts. Many persons, not electricians, if it were done gradually, would hardly know the falling of 15 volts—would not know that it was much below. They could read by it very well. He had found on circuits in London variations of more than 8 per cent. There was a 40 per cent. variation in the Athenæum Club.

After cross-examination on statements which he had made at various lectures, the WITNESS said that the "bubbling" of a cell indicated over-charging. Every practical electrician knew what was meant by thoroughly charging up; it meant when the specific gravity of the electrolyte was brought up to the proper density, he adopted 1,200. The only way to keep a battery in good order was to have a hydrometer continually at work.

After a few questions about "earth," Prof. FORBES, re-examined by Mr. MOULTON, said that a passage in one of his lectures which had been referred to related to the high-pressure system of charging batteries in series, and discharging them after shutting them off from the charging mains. The use of feeders would not prevent the Lane Fox system from having its regulating effect.

[This concluded the case for the plaintiff.]

Sir HORACE DAVEY, in opening the case for the defendants, confessed that they took a radically different view of the meaning of the patent from that put forward by the other side. In the first place, he contended that there was no patentable invention; that the so-called invention merely consisted of putting side by side two known things, each of them operating and intending to operate in the old manner; that there was no thought or application, and no direction—no invention shown in the manner of the combination. Secondly, that the combination had been anticipated both by Clark and by Achard; that it was a combination for supplying electricity by the joint action of a generator, a source of electricity, and a secondary battery for the purpose of sending a current through for using at a particular point, and that it does not make the slightest difference for what purpose the current of electricity is used. It merely consisted of passing electricity to the required point for use at that required point. Thirdly, the so-called invention as described in the amended specification was useless for any practical purpose. It was useless for the purpose for which it was described. In the first place, the earth—the actual earth—was absolutely impracticable for the purpose for which it was described in the specification. Without a system of extra cells and switches it was impossible to work what was described in Lane Fox's specification for the purpose of storing electricity to be used when wanted. The patentee, according to their view, described a system by which electricity was to be stored up in a reservoir. It may be that it had the incidental advantage of regulating the electromotive force of the currents. It was an incidental advantage. It was not invented by the patentee. It was inherent in the thing itself. A man could not take out a patent for discovering a new property of an old thing. If you used Planté batteries as reservoirs for storing up your electricity, you would also gain the advantage of regulating your current. Whatever was the merit of Mr. Lane Fox's suggestions, they remained in the region of suggestions, and had never gone beyond it—crude suggestions stated with many details which were absolutely unworkable, and, even when the matter was narrowed down to the form in which they saw it now, they remained still crude suggestions without any sufficient description or directions enabling those suggestions to be carried out in the form of a workable machine.

The two principal grounds upon which they attacked the insufficiency of the specification were, first, that the patentee directed them to use very large conducting surfaces in the cells. It was incumbent upon the patentee to tell them how large. The witnesses said, "Oh, but you are not to charge fully, and you are not to discharge fully." There was nothing of the kind in the specification. His learned friend the Attorney-General invented a phrase which did him the utmost credit. The phrase which he used was "the *plateau*." There was nothing about the plateau in the specification, and no direction in the specification which led in the direction of the plateau. His friend might be quite right for aught he knew to the contrary. Then, again, about the other cells. His client's system was a totally different one. For the purpose of storage it was absolutely essential that you should use extra cells which were capable of being put in and out and worked by a complicated arrangement of switches. No gentleman had come to say that he had ever heard of any application of this combination without the system of switches, with the exception of the laboratory installation of Prof. Barrett, and those two or three hours that the lamps were run at Lady Conyers', which of course he would have to deal with. But in every case, whether they had been put in at the instance of Mr. Lane Fox—as at the Brush Company's—or under his directions, as the lamps in the Opera House in Vienna, or at the King of Roumania's Palace at Sinaia, near Bucharest, or at the Drapers' Company under the direction of Prof. Silvanus Thompson, or whether it was at any of the installations which were mentioned by Prof. Forbes, at every one of them they would find that in fact these switches were found necessary. That was a very striking fact. According to their view, their combination or system was strikingly different; it was a different combination, it was a different system altogether. They had, going from the central station, various branches called "feeders," which lit a small portion of the district. The feeder was brought back to the main so as to form a complete circuit. They did not think secondary batteries useful for the purpose of regulation at all—they did not want them for that purpose; what they wanted them for was for supplementing the work of their dynamos for economy, for enabling them to work with smaller plant than they would otherwise be able to do.

[Sir Horace Davey then went on to the bench and explained a model at length to his lordship.]

His witnesses would offer any explanations which might be necessary upon the complicated and beautiful system by which from time to time the quantity of current and the potential were adapted to the needs of the installation. It was found by practical men that if you let the batteries discharge there was a gradual, sensible, susceptible, mischievous drop in the current. Mr. Lane Fox would not agree that it was so large as their witnesses had observed it to be; but he agreed that there would be a drop in the current which would operate to lower the potential on the whole system. It was to meet that drop that they from time to time brought into operation additional batteries which were ready charged. There were a great many people at Lady Conyers' ball. They could not

Digitized by Google

all be dead. Not one of them had come, except Mr. Lane Fox, to tell them anything about that installation. It was one of the misfortunes of Mr. Lane Fox that there was always something that prevented the success of his schemes. At the Law Courts, where Mr. Crompton superintended, Mr. Crompton did not know the "A B C," it was notorious that Mr. Crompton was too stupid! It might be so; but Mr. Crompton had put up a larger number of installations, certainly in England, than any living man. Then workmen were so stupid, they did not understand! He quite agreed. What did it all point to? That the directions were insufficient. They could not all be Lane Foxes. It was idle for Mr. Lane Fox to come before the Court and say that the reason why this had not been carried out was because there was a conspiracy against him among the Directors of the Brush Company. The patent had been amended in such a way as to make it appear that there was a patent for automatic regulation, when the patent which was originally granted was granted for something wholly different. He could not strike out the whole of his detailed description of his regulator, and then say, "I have still got a patent for regulating electric light, because what I have described there for another purpose will operate as a regulator." All he told them about regulation was that the regulation was to be effected by the regulator.

THURSDAY, MARCH 3RD.

Sir HORACE DAVEY, continuing his opening speech, called attention to the disclaimers, and submitted that the word "regulating" ought to have been struck out, because regulating in the original patent did not refer to any automatic action of the secondary batteries, but it did refer to a mode of regulation which the patentee said was necessary for the working of the system, and which he called "my regulator," and which he claimed as the mode of regulation which he had patented. You might, no doubt, strike out of the specification—the law was very indulgent—a thing a man had put in by inadvertence, or things he had put in thinking they were novel. But you could not alter what was left by making it a new invention or a different invention (Ralston v. Smith, 11th House of Lords, p. 223), so as to make the patent when disclaimed claim a different invention from that which was claimed by the original specification. In the original specification he meant regulation by the regulator, which he said was necessary for the success of his system, with an added recommendation that it was advisable or desirable to use a large number of secondary generators and generating machines. He struck out that which he described as the regulator or as the necessary regulator, and then said, "I still have a patent for regulating the electric light." How could he? It altered completely the scope of the patent.

The principle upon which the lamps should be constructed was indeed stated. It was, in fact, intended to be an incandescent lamp; but if the lamp was part of the mode claimed he did not claim the lamp as such; but if, as Prof. Barrett seemed to think and Mr. Lane Fox himself obviously thought, he was the author and was entitled to the honour of the discovery of the lamp which alone had made incandescent lighting a successful mode of lighting, then that lamp was a useless lamp. Mr. Lane Fox stated in this, as he did in a great many of his patents, general principles, but he failed to work them into successful details. The peculiarity of Edison's patent was a filament of carbon, and enclosed in as perfect a vacuum as could be got.

He now came to the description of distribution. "The way in which I distribute the electric energy is as follows:—From one pole or electrode of the electric generator or generators situated at A, Fig. 3 (see *The Electrician*, February 26th, p. 438), proceed one or more large conductors, from which branch out, at various points where lights are desired, smaller conductors, which again may have conductors branching off from them, and so on; the other pole or electrode of each electric generator is connected with the earth, so that the conductor and its branches and sub-branches will be perpetually in a state of electric tension, tending to develop currents in every direction to the earth." Now, a faint attempt had been made to suggest that that mode of distribution as such was new. There was a claim for it. It had been disclaimed as of doubtful utility, and as of doubtful validity.

Mr. JUSTICE A. L. SMITH: It still stands in the patent, does it not?

Sir HORACE DAVEY: Not for the mode *per se*, only for the combination. It all came back to this, that it was the parallel system of arrangement as distinguished from the series system of arrangement in lamps, and the very name "multiple arc" showed that it had been introduced and was known in the days of arc lighting. There was no novelty in it.

Some of Mr. Lane Fox's experts thought that "the earth" meant every kind of return conductor; others, including Mr. Lane Fox himself, though he was a little uncertain about it, that it meant not every kind of return conductor, but an uninsulated conductor, "any return conductor where isolation is not required." Now, where a patentee described a particular mode, then that particular mode was an essential element of his combination, and that Mr. Lane Fox expected to derive particular advantages from using the earth as a return conductor. Even if the use of the words "the earth" was intended to cover all conductors of every kind whether insulated or uninsulated, still it at any rate included the earth; and, further, he would endeavour to establish by evidence that it had been tried and it had been found practically useless for the purpose of electric lighting. If a return by means of the earth itself was part of the plaintiff's combination, his answer was, they did not use it, and, therefore, did not infringe that particular combination, and the patent being a combination of several things, each of which was not claimed either as a novelty or as being useful, and had in fact been disclaimed, then the patentee was confined strictly to the combination which he had described.

Mr. JUSTICE A. L. SMITH: He does not claim anything for this in the patent.

Sir HORACE DAVEY: He claims the combination.

Mr. JUSTICE A. L. SMITH: Do you say it is necessary to infringe all parts of a combination?

Sir HORACE DAVEY: You must infringe the essential parts of it, my lord, and if this is part of the description from which he sought to get an advantage, then it is an essential part of the combination.

In his original patent Mr. Lane Fox claimed the mode of distribution *per se* as a separate invention; he claimed the mode of measuring *per se* as a separate invention; he claimed the mode of regulating; he claimed the mode of obtaining light. Well, of course, they could not do any one of those things without infringing his patent; but he had struck all that out and disclaimed it all. His patent was now confined to a combination of A and B. It was therefore a pure combination patent.

The ATTORNEY-GENERAL: A combination claim, I agree, not a combination patent.

Sir HORACE DAVEY: I do not know what my learned friend's distinction is. If they used "A" and "B" in exactly the same way as they had heretofore been used, but without any invention or ingenuity in the mode in which "A" was applied to "B" and the combination was formed, then there was no invention in the patent. [Lister *v.* Leather (Elli - Blackburn); Harrison *v.* The Anderston Foundry Company; Clark *v.* Adie (two appeal cases, p. 315); Murray *v.* Clayton (Goodeve, p. 314, 7th Chancery Division, p. 570)].

Mr. JUSTICE A. L. SMITH: Supposing it was feasible in 1878 to come back by earth (I do not say it was) and then the Board of Trade intervenes afterwards, would that smash up the patent?

Sir HORACE DAVEY; No, my lord.

Mr. JUSTICE A. L. SMITH: Then you must say it was unfeasible in 1878.

Sir HORACE DAVEY: Yes, my lord; the directions of the Board of Trade cannot make any alterations in the rights of a patentee. It can do a great many things, but cannot alter the laws of nature.

Mr. Lane Fox tells us we are to use our battery as a reservoir, so that by increasing the electromotive force during the hours when not much electricity is being used, they will become charged. What was the meaning of "charged"? That was English language. They did not want the gentleman to tell them that. That was a question of the meaning of the English language. Would his learned friend say that when a toast-master at a City banquet asked the company to charge their glasses in order to drink the Attorney-General's health, that that meant to fill them three-quarters full? To charge a vessel meant to fill it. He had no doubt that the direction was that the batteries were to be charged—not necessarily overflowing—nobody was so absurd as that—but that they were to be charged. In addition to the absence of any directions for not charging the battery beyond what was called the plateau, the absence of that was very much confirmed by what he now took to be an established fact by Prof. Forbes, although it was denied by Mr. Lane Fox, and that was, that the batteries rapidly deteriorated if they were not charged to their full extent. The expression used was it was necessary for the "health" of the cells. Mr. Lane Fox having made some suggestions, he now asked that those suggestions may be read and put in force, and he came forward now in the fourteenth year of his patent to ask that these suggestions should be read by the light of accumulated experience, which had been gained since the incandescent light had been introduced, and to be put in force by the law. The directions in the patent were wholly insufficient. There were no directions, and they had no right to impose upon the electrician or the workman who had to take the patent in hand the labour of experiment and trial—of failure, it may be—experiment, trial, failure, or ingenuity; and it was not enough to produce it to Sir Frederick Bramwell, or Dr. Hopkinson, or Prof. Silvanus Thompson, and say, "Can you carry this out?" The process was to be worked by a man with 30s. a week. What was the workman to do? How was the workman, from the vague general direction that the cells were to have a very large conducting surface, to know all that was required? How was the workman, from a direction that he was to use the batteries as reservoirs, and that he was to charge them during the hours when there was not much light burning, to know that he was only to charge them up to a certain undefined limit?

Mr. JUSTICE A. L. SMITH: They say on the other side that the engine-driver must knock off when he gets his light too bright.

Sir HORACE DAVEY: Then you will not store the batteries.

Mr. JUSTICE A. L. SMITH: They say you have got it up to the plateau.

Sir HORACE DAVEY: Yes, but you will not store your batteries. The answer to that is twofold. In the first place, you will not store your batteries, and, in the next place, you are told here that the electromotive force is to be increased, so that the engine-driver is told to increase his electromotive force during those hours. He is expressly told so.

Coming to the last part of the patent, namely, what his friends called "regulation." He had already pointed out that the patentee had left out one part of the sentence. It was the first time in his limited experience that he had ever known an amended specification which stopped at a semi-colon. If they looked at page 5 they would see: "In order to keep the electromotive force in the electric mains constant, it is desirable to have in the first place several generating machines, also a number of reservoir batteries as before explained" [semi-colon] "next it is necessary to have some regulator such as that about to be described." He stopped in the middle of the sentence, he struck out "next it is necessary." It was the first time in his legal experience that he had ever known of a case in which one retained "in the first place," and struck out what was to happen in the next place. He ventured to say that this alteration completely altered the meaning and scope of the patent, that it gave an entirely new meaning to the words in the title of the patent and in the claim at the end. He might observe again what one always noticed in Mr. Lane Fox's patents—the vague, general, large language—how it was desirable to have "several" generating machines. How many? "Several generating machines." How could anybody be said to infringe that? Did they infringe it if they had had two? And if so, why? According to Mr. Lane Fox's view, the object

Digitized by Google

of sprinkling or dotting secondary batteries about the system was to secure local constancy. If that were a material part of Mr. Lane Fox's system all he could say was that they did absolutely nothing of the kind for the purpose of equalising and getting rid of the resistance in the mains, which would no doubt affect the actual amount of potential at any particular part of the system. They had a totally different device. They had a system of what was called feeders. The feeders went direct from the station. There was a feeder for different parts of the district which they lit. They went direct from the station, and they returned to the mains, the consequence of which was that they did not affect that particular district by the loss in the mains which would result if the main were taken to the district itself, and there was all the loss by resistance, when loss had taken place in the main before it was rejoined by the feeder which had taken the current to the district; and, therefore, if that was Mr. Fox's system of regulation, then all he could say was they did nothing whatever which in the remotest degree resembled it. The wires which connected the battery at Queen's Gate with the dynamo which actuated it at Kensington contained no lamps. They were called "charging mains," but Mr. Lane Fox spoke contemptuously of the name. He said, "You call them charging mains." In no sense whatever was this battery in Queen's Gate placed between the mains and the earth, as described by Mr. Lane Fox. Even if he conceded that Mr. Lane Fox had discovered what the world did not know at that time, that a secondary battery when used for the purpose of storage would also have the effect of regulating and steadying the current, that would not be subject matter for a patent.

Mr. JUSTICE A. L. SMITH: Not if he stated it in his patent?

Sir HORACE DAVEY: I think not, my lord, because he would be merely stating a property which was inherent, as the witness said.

Mr. JUSTICE A. L. SMITH: Supposing he found out that it was inherent?

Sir HORACE DAVEY: I think not. A man has been accustomed to eat his soup with a spoon, and somebody suggests that to use a spoon would be a good way of eating peas, which puzzle some people. You could not have a patent for that. It is an inherent part of the advantages of a spoon. That is, of course, a most vulgar illustration; but it is an illustration which is frequently given. You cannot take out a patent for teaching a person the best way of using a machine which he has got.

Mr. JUSTICE A. L. SMITH: Which nobody knew how to use before?

Sir HORACE DAVEY: Yes, suppose nobody knew how to put that machine to beneficial use. If he introduces an amendment into that machine—an alteration in that machine—which will enable it to do work which it could not do before, that is the proper subject of a patent; and if a man merely discovers a more beneficial way of using a new machine without making amendments in the machine or altering the machine, or altering the general purpose for which it is to be used, he cannot get a patent for that, because that is nothing more than teaching the world the most beneficial use to which to put the machine. Planté has told you his cell will store electricity for as long as you like or as short a time as you like, and it will give it out when wanted; but somebody says, "I will tell you what it is. If you use that in connection with an electric current, you will find it very useful for taking up flickering." That would be merely telling me of a useful application which I can make of my own machines. You cannot get a patent by pointing out to me the inherent properties which I do not know of the patent—which I am perfectly ignorant of, and which you perhaps have discovered—the inherent properties of that machine. You cannot get a patent so as to prevent me using that machine in the way which is most beneficial and profitable to me.

FRIDAY, MARCH 4TH.

Continuing his speech, Sir HORACE DAVEY cited several cases to show that combination of well-known things, without invention, was not a proper subject for a patent. "Horton v. Mahon" was an action for infringement in the construction of gasholders. The old way of making a hydraulic joint was to rivet two angle irons together. The patent was for the use of double angle iron or channel iron for this purpose. It was perfectly apparent and palpable that double angle iron would answer the same purpose, and save two rows of rivets, and consequently much additional labour. The whole claim of the patentee, therefore, amounts to this—he informs the manufacturers of gasholders that by the use of an article well known in the iron trade much labour and expense may be spared. That clearly is not the subject of a patent. And he said that if they use a reservoir in the mode in which a reservoir was used, without any change in the construction of a reservoir, merely taking a well-known machine, Planté's cell, and he tells them they can use it beneficially with a current for incandescent light—that that is not the proper subject matter of a patent. He returned to the failure of the early installations, and said that Mr. Lane Fox showed absolute indifference as to the fate of the specimen installation at the offices of the Brush Company. The plaintiff proposes to start his batteries or let them start themselves, and to let them discharge themselves at their own sweet will; but they proposed, on the contrary, to confine and control—keep the electric current always under the control of a manipulator by means of mechanical devices, and to adjust their current from time to time in such a manner as to enable them to achieve that object. On the whole, he submitted, whatever may be the merit of the general principles which are announced in it, it was a bad patent, and one which did not entitle the patentee to the protection of the Patent Law; and, in fact, the patent itself, he did not hesitate to say, was a mere statement of crude and undeveloped general principles, and of vague generalities, which required experiment, thought, and ingenuity to supply details which would carry them into effect; and he submitted that, on the evidence which would be produced, the Court must come to the conclusion there had been no infringement by these defendants of the plaintiff's so-called patent.

On the same day Sir Frederick Bramwell was the first witness called for the defence. He gave some figures to show the small saving which would be effected by the use of earth return, and the great cost which would be incurred by enlarging the batteries. He drew a diagram to represent the connections of the circuit described in Clark's specification, and put in a copy of the map published as a Supplement to *The Electrician* of January 15th last with the junctions of the feeders marked on it. He explained the model which was made at his instructions to show the working of the defendants' system. He was cross-examined at considerable length by the Attorney-General, and was re-examined by Mr. Finlay on Saturday.

Dr. John Hopkinson was examined by Mr. Wallace, and was cross-examined by the Attorney-General, on Monday, the 7th inst. He was confronted with a favourable report which he had made on the Andrews system of wiring, and with his evidence before a Select Committee in 1879. He was re-examined by Sir Harace Davey, who afterwards examined Mr. Crompton. A number of tables of tests made to refute Prof. Perry's evidence was put in, and showed that with only 1 per cent. above the normal volts a cell rapidly sulphated, hardly any charge going in. Mr. Crompton described an unsuccessful attempt to get an earth return by the Thames at Henley in 1879 or 1880.

On Tuesday Mr. Crompton was cross-examined by the Attorney-General, and was questioned on several statements made by him in Papers and at discussions at scientific societies.

The case was adjourned till Monday next, and it was understood that it will probably conclude on Wednesday. Our abstract, commencing with Sir F. Bramwell's evidence on Friday, last week, will be continued in our next issue. We take this opportunity of giving the grounds for the action.

The plaintiff is the registered owner of Letters Patent No. 3,988 of 1878, and he alleges infringement of the same to have taken place by the use of secondary batteries as reservoirs of electricity in combination with a mode or system of distribution substantially the same as that described in the specification. The modes of distribution complained of are alleged to be (1) the use of the secondary batteries in combination with a number of lamps placed in multiple arc between two main leads; (2) the use of secondary batteries in combination with two or more systems of multiple arc distribution, in which one or more of the main leads are common to two or more of the said systems. The defence is (1) that the plaintiff is not the true and first inventor; (2) that at the date of the issuing of the writ the plaintiff was not the owner of the letters patent; (3) non-admission that the plaintiff is the registered owner; (4) want of utility; (5) invalidity of patent on several grounds, such as improper subject-matter for a patent, want of novelty, non fulfilment of condition by filing a proper description of the invention within six months after the grant of the patent, differences between the provisional and complete specification, anticipations by prior patents and publications.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *February* 26, 1892

The Meeting of the National Electric Light Association at Buffalo.—The event of the week has been the meeting of the National Electric Light Association at Buffalo. The Convention began on Tuesday last, and extended over three days. It was somewhat different from previous Conventions in that a vigorous effort was made to transact more business and do more profitable work in the comparatively short space of time. The result was very successful, and it was the most business-like Convention in the history of the Association. The opening Session of Tuesday was devoted to a formal address of welcome from the Mayor of Buffalo and the response from the President of the Association, and a few Committee Reports. In the afternoon work was taken up in earnest, and a Paper by Mr. L. B. Stillwell, "On the Relation of Size and Efficiency in Transformers," was read. In the discussion Prof. Thomson and Wm. Stanley, jun., took prominent part, and a good deal of interesting information was the outcome. The Committee on Safe Wiring then reported, bringing before the Convention some matters which had been referred back to them at the previous Convention at Montreal. Some amendments were introduced, and the rules were then promulgated. Following this were two or three Papers of minor importance. In the evening the subject of the transmission of power came up for discussion. It was opened by Mr. Carl Hering, who discussed the situation as exemplified by the Lauffen-Frankfort transmission of power plant. The speaker was an enthusiastic advocate of the three-phase system. The matter was discussed by half-a-dozen men, chief among them Prof. Elihu Thomson, who expressed himself as believing thoroughly in the coming era of the transmission of power at very high pressures. He suggested that in such cases it would be desirable to place the mains underground, and suggested holding the high-pressure conductors in iron pipes filled with oil. During the discussion a great deal was said about the proposed transmission

Digitized by Google

of power from Niagara Falls to Buffalo and Chicago. On the succeeding day the most important feature of the morning session was the Paper by William Stanley, jun., on the alternating motor, with special reference to the new type with which he is experimenting in company with Mr. Kelly. He has succeeded in obtaining some remarkable results with series or shunt-wound motors in connection with condensers and similar devices. In the succeeding discussion Mr. L. B. Stillwell gave considerable account of the results that had been recently obtained from the Tesla two-phase motors. Prof. Elisha Gray, of Chicago, was then introduced, and explained the plans for the Electrical Congress of the World's Columbian Exposition. Inasmuch as no Association or Society can take part in this Congress as an organisation, the matter had comparatively little interest for the majority of the delegates so far as official action was concerned. A Committee was appointed to take Prof. Gray's propositions under consideration, and the succeeding day reported in favour of encouraging the attendance of members at the proposed Congress, but took no more definite or formal action. On Wednesday afternoon some 300 delegates out of the total attendance of nearly 500 made a special trip to Niagara Falls to visit the work of the Cataract Construction Company. The tunnel is now far advanced. The Brush station near the Falls is interesting both from being driven by turbines supplied from Niagara River, and as being one of the few examples of cotton-rope transmission in this part of the country. After the return from Niagara a session was held in the evening, at which the principal feature was a long Paper by Erastus Winan on the financial side of the electric lighting industry There was some further discussion regarding the Electrical Congress at the World's Columbian Exposition; but the Association really took little interest in the matter, although, under proper conditions, it would have been considered very desirable to hold a Summer Convention at Chicago at the time of the Congress. The last day's proceedings were of considerable importance from a practical standpoint. The most striking Papers were two on underground service by Mr. E. A. Leslie and Mr. Craven. The latter gentleman discussed the underground system for the feeders of the Buffalo Street Railway Company. This pair of Papers provoked a good deal of interesting discussion. The afternoon was devoted to executive session, and the election of officers. Mr. J. I. Ayer, of St. Louis, was elected President, and (omitting the Summer Convention) the next meeting of the Association will be in St. Louis in February, 1893.

SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

COPENHAGEN, *March* 1, 1892.

A proposed telephonic installation of considerable extent, and possessing several characteristic features, is at present attracting much attention in Norway. I refer to the Christiania-Bergen trunk line, which will have a length of some 300 miles, and will have to be carried across high and snow-clad mountains. The matter has been referred to the able manager of the Stockholm General Telephone Company, who has great experience of long telephone lines. The Stockholm Company has during the last few years installed several long lines, and has used copper wire. These wires have electrically proved satisfactory, but with rime and snow there have been many mishaps and contacts, so the Company has now adopted bi-metallic wires of double the breaking strength and with a conductivity of 60 per cent. that of pure copper. These wires have, however, hardly been practically tested for a sufficiently long time to form a definite opinion as to their merits, but they seem to answer well. It is thought that a fee of 50 öre (6d.) for three minutes' conversation would enable the Company to pay the shareholders a fair dividend, as well as providing for a sinking fund.

Some very interesting observations were made at the Christiania telegraph station on Saturday and part of Sunday (February 13th and 14th). There was a splendid aurora, and all telegraphing was difficult. Lines usually capable of taking two or three telegrams at the time could only be used for one, and this with constant interruption. This led to endless confusion and complications. The line to Stockholm was almost useless; telegrams handed in at Christiania at noon only reached Stockholm at eleven p.m. The line to Drontheim was even worse; telegrams handed in at Christiania at noon on the Saturday did not reach Drontheim till Sunday morning. On Saturday evening there were four hundred telegrams for Drontheim and the north waiting at Christiania to be despatched.

The State telegraphs in Sweden have during 1891 forwarded 1,849,469 telegrams, against 1,255,329 in 1890, an increase of rather more than 5 per cent. The receipts for telegrams during 1891 amounted to about 1,410,000kr. (£70,500), an increase of about 1½ per cent.

The State telephones in Sweden are not only being continuously extended, but the use of the telephone is also rapidly increasing. On the important Stockholm-Gothenburg line (150 miles), which goes right across Sweden, the number of conversations during 1891 was 74,201, yielding a revenue of £2,100, against £1,025 during 1890, an increase of more than 100 per cent. Parliamentary grants will be asked this year for a number of new lines.

CORRESPONDENCE.

THE CHATHAM ACCIDENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I beg to forward the following facts in connection with the accident:—The foreman of linesmen, named Readwin, had been engaged in replacing a transformer for one which he supposed had been burnt the day before, from the fact that the lamps in the shop refused to light. The same thing occurred with the fresh transformer (that is, the refusal of the lamps to light); and, not finding anything else wrong to account for this, he supposed that there must be a loose connection in the primary work in the house. As a matter of fact, however, one of the service lines had become detached from the main which passes over the roof. Readwin, not knowing this, tried the connection with the fuse box by pulling the wire, which happened to be the one that was still connected to the main, but without removing the fuses. The cause of his receiving a shock was owing to the service lines being placed on a very damp wall, and sufficient moisture having gathered on the surface of the insulation to cause the current to flow from the connection in the fuse box along the surface of the insulation; and Readwin, stepping from the dry board on which he was standing to the damp earth, received the current through his body. The shock immediately drew him up, bringing his whole weight to bear on the wire, until, by falling, he jammed the cable between the back of the fuse box and wall, upon which the damp wall took the current, and so released him. He was conveyed to the hospital, where they detained him, owing to severe burns to his hand and foot.

The young man who died, named Jay, was a salesman in the clothing department of Messrs. J. W. Taylor and Co. Jay, seeing the place filled with smoke owing to the burning of the insulation, and thinking the place was on fire, rushed down stairs with an iron bar in his hand, accompanied by one of the workmen from the tailor's shop. The evidence of this workman at the inquest was that the deceased did not get within striking distance when he (deceased) fell back into his arms. The four doctors in their evidence said that deceased lived for five minutes or more after the accident.

Owing to the fact of all or nearly all the organs being congested and the blood changed to a tarry consistency, this, together with the entire absence of the symptoms of death by a fit, and the fact of the deceased being perfectly healthy up to the time of his death, were the reasons they gave that deceased met his death by electricity; they had never seen a death caused by it. There were no marks of burns on the body. The jury returned a verdict of death by electricity through misadventure, as deceased had been warned by three people not to touch the wires.—Yours, &c.,

G. PEPPER, Secretary,
Chatham, Rochester, and District Electric Lighting Company (Limited),

Rochester, March 9, 1892.

THE FUNCTION OF A UNIVERSITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Yet one more definition—it is no part of the business of a University to *teach*, says Prof. Fitzgerald, in *Nature* for February 25th. We have now the following as the definitions of the functions of a University:—

1. It should be a mere examining body—*e.g.*, the London University.

2. It is a place for the cultivation of athletics, good breeding and gentlemanly behaviour.

3. At the University there should be taught classics, mathematics, and the pure sciences.

4. The professors at a University should teach *useful* subjects, like mechanical and electrical engineering, medicine, &c., as at Cambridge.

5. The true function of a University is the teaching of *useless* learning.

6. It is no part of the business of a University to *teach*.

Truly, a wide choice of definitions! And seeing that the teaching of applied science which has been developed "at schools, technical colleges, by patent mongers, and the trade," aided "by a lot of savages," has been recently appropriated by the Universities, I have no doubt when these degraded mortals have similarly worked out a system of teaching applied literature, that a seventh definition of the function of a University will be added later on, viz.:—

7. At the University modern languages and literature are studied in such a way as to be of the greatest value to the nation at large.

As Prof. Fitzgerald relegates the teaching of things useful to the class of pariahs mentioned above, perhaps he will tell us whether he raises the study of mechanical and electrical engineering to the lofty position of uselessness, or whether he utterly condemns the appeal that is now being widely made—made even to technical teachers—for aid in the establishment of engineering laboratories at a University which has recently thought that the best place to obtain an assistant was a London technical college.

He thinks that students, "if they are so ill prepared that they have not acquired the art of learning, should go to a College, . . " and not to the University. I presume, then, that they ought to go, for example, to the Colleges of Trinity or St. John, but not to Cambridge; or to the Colleges of Balliol or Christ's, but on no account to Oxford. Perhaps this somewhat conflicting advice is the result of Prof. Fitzgerald's studying literature "for its own sake," as contrasted with studying language for the sense it conveys. Examples were recently given in a leader in one of the daily papers, illustrating that the public utterances of some of the most prominent advocates of the compulsory teaching of Greek conclusively proved that it was not to improve their English that they had studied the classics.

In the same lucid way Prof. Fitzgerald adds, "The Bible produced very little effect until it was read in translations, and the danger of a pagan revival, if ancient literature were studied without the obstruction of difficult languages, is the best reason for insisting on these languages in a Christian University." Surely a man of his wide intellectual power cannot mean that the general reading of the Bible, which became possible after it was translated into modern languages, is to be deplored. But neither, on the other hand, can he mean that the incalculable benefit that has resulted from the translation of the Bible into the vulgar tongue, is an argument for the suppression of free translation. On whichever horn of his own dilemma he decides to pose himself, I, at any rate, have no sympathy with the Roman Catholic dogma, that good comes from making the knowledge of the truth difficult of attainment by the world at large.

He chides me with forgetting the debt electrical science owes to those who studied it while useless. Does the statement that one *volt* sends one *ampere*—that is, one *coulomb* per second—through one *ohm* look as if the practical engineer had forgotten the labours of Volta, of Ampère, of Coulomb, and of Ohm? Indeed, is not Prof. Fitzgerald forgetting the deep debt of gratitude the theoretical study of electricity owes to its practical applications? The late Prof. Fleeming Jenkin, a professor at a University bear in mind, wrote in 1873, "In England, at the present time, it may almost be said that there are two sciences of electricity—one that is taught in ordinary text-books, and the other a sort of floating science, known more or less perfectly to practical electricians. . . A student might have mastered De la Rive's large and valuable treatise, and yet feel as if in an unknown country and listening to an unknown tongue in the company of practical men. It is also not a little curious that the science known to the practical man was so to speak, more scientific than the science of the text books.'

While there are University Professors like Thomson, Hertz, and Fitzgerald what matters it whether we call them the *teachers* or ourselves the *learners*? When the work they are now carrying on may be of incalculable service to the practical man in the future, of what avail is it to discuss whether it is to-day *useful* or *useless*? For such labours I have too profound a respect and admiration to "sneer" at what I hold to be the true function of the University.

But equally worthy of respect, do I think, is the *teacher* in a *school* of engineering—that is, one who aims at presenting useful knowledge, and the methods for extending it, in such a form as to be most easily grasped by those who intend to devote their lives to engineering.

My friend Prof. Fitzgerald and I are, at any rate, wholly in accord on one important point, urged in my recent inaugural address, viz., that it is the special function of the technical school to teach *useful* knowledge.—Yours, &c.,

W. E. AYRTON.

[Prof. Fitzgerald's letter to *Nature*, to which Prof. Ayrton alludes, was reproduced on p. 450 of our last issue.—ED. *E*.]

CABLE TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR. Would you kindly allow me space in your columns to point out the fact that a cable transformer, consisting of a stranded iron rope surrounded with two separate windings of copper wire, similar to the present Siemens' cable transformer, was patented by me in France on April 3, 1886, Patent No. 175,242.—Yours, &c.,

C. E. L. BROWN.

Baden, March 7, 1892.

ELECTRIC LIGHT CABLES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to the correspondence opened in your journal recently on the quality and durability of vulcanised rubber cables, there are several points that have not been touched upon, yet are of no mean importance in guiding the user to secure a good insulation. Foremost among these is the separator, or intermediate covering between the pure and vulcanised rubber or jacket. The true function of the separator seems scarcely known or appreciated by the younger firms in the cable business, as it is often left out altogether; even many of the older companies seem to have forgotten, or to ignore, the importance attached to this covering in the old telegraph days.

The separator could consist of a non-vulcanising rubber compound, its object being to act as a sort of trap to prevent the sulphur penetrating to the pure rubber, and thence to the wire, which, if not prevented, is sure to bring on chemical action and decomposition. The separator made in this way is only cured on the outer surface by absorption of sulphur from the jacket, and should remain comparatively soft. All important cables, at least, should have such a separator. In heavy cables this covering need only be thin in proportion to the vulcanised covering. A good criterion that the sulphur has not penetrated is that the tinned wires should remain perfectly bright.

Another point seldom touched upon, but which should be seen to, is that the wire is perfectly concentric with the covering. I have seen examples recently where in places there was little more insulation than what the cloth tape afforded.

Lastly, from a life-long experience in every detail of manufacture and testing all descriptions of insulated conductors, I have more confidence in coverings that have been put on in

Digitized by Google

two or more layers than those that have one covering only of equal total thickness. No matter what care is taken in the manufacture and preparation of materials, and how perfect the machinery, faults will happen, and they are more easily detected during the manufacture in two or more layers than one thick covering, and are less likely to be as serious or do so much harm.

Perhaps the points I have raised are more properly questions for manufacturers to settle for themselves; but their discussion, and the proper ventilation of various opinions, is bound to be of benefit to the trade at large.—Yours, &c.,

JAMES CONNOLLY,
Electrician to the International Okonite Company (Limited).

Newton Electric Works,
Manchester, March 8, 1892.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—Our advertisement columns contain an announcement that tenders are invited for lighting by electricity the buildings and grounds of the International Exhibition, to be held in the Isle of Man during the months of July, August, and September. Specifications and full particulars may be obtained from the Secretary.

———— Tenders are required for maintaining the electric light installation at Falcon Cliff Grounds, Douglas, Isle of Man, full particulars of which are to be obtained from Mr. Rowe, secretary, Cliff Company, Douglas.

SALE BY AUCTION.—Messrs. Weatherall and Green announce in our advertisement columns that they will sell by auction, on the 28th inst., some valuable freehold and leasehold property at the London Docks.

ELECTRICAL ENGINEERING CORPORATION (LIMITED).—We regret to learn from Mr. F. W. Pixley, the receiver and manager of the estate of the Electrical Engineering Corporation (Limited), that it is unlikely he will be able to pay the debenture holders 20s. in the pound, and that therefore nothing can possibly come into his hands for the unsecured creditors.

INSTITUTE OF MEDICAL ELECTRICITY (LIMITED), IN LIQUIDATION.—We understand that a dividend in this matter will shortly be declared.

MAXIM-WESTON ELECTRIC COMPANY, LIMITED (IN LIQUIDATION).—Meetings of the shareholders of the two Maxim-Weston Companies will be held, for the purpose of receiving accounts of the windings-up at Cannon-street Hotel on April 8th—in the case of the first liquidation at 12, and in the case of the second Company at 12:30.

MESSRS. MATHER AND PLATT.—Some considerable improvements have recently been effected at the central station, Manchester, by the adoption of the electric light, for which Messrs. Mather and Platt have supplied the engines and dynamos, Messrs. Galloway supplying the boilers. The installation consists of 40 arc lights of 2,000 c.p., each distributed over the platforms and approaches. The offices, &c., are lit by means of 16 c.p. incandescent lamps, and the public rooms are supplied with handsome electroliers. The generating plant is conveniently placed beneath the Viaduct, from which position power is supplied by two powerful compound engines; and the whole plant of engines, boilers, and Edison-Hopkinson dynamos is in duplicate, with specially-designed arrangements and every precaution to guard against failure. The Cheshire Lines Committee are, we understand, so gratified with the result of this installation, that they have commissioned Messrs. Mather and Platt to light the whole of their extensive goods depôt, which will require, it is estimated, 76 1,000 c.p. and 10 2,000 c.p. arc lamps, and 65 16 c.p. incandescents, which are expected will be at work in the spring, and will result in the entire discarding of the use of gas for the electric light. The general arrangement of the lighting has been supervised by Mr. W. S. Scott, general engineer of the Cheshire Lines Committee, and is undoubtedly one of the most important railway installations in the Kingdom.

MCWHIRTER, FERGUSON AND CO.—This firm has been entrusted by Messrs. Edward Lloyd (Limited) with the lighting of their large paper mills at Sittingbourne, where the new mill just finished is entirely lighted by electricity. Two Faraday dynamos of the latest type have been put in, driven by a 160 H.P. engine. The installation is, we understand, giving satisfaction; and, as a consequence, suggestions have been put forward for lighting the town of Sittingbourne by electricity.

DOMESTIC ELECTRICITY.—Messrs. Crompton and Company and the General Electric Company, have added to their exhibits at the Crystal Palace Exhibition a new department, and what may be termed a new departure. They have fitted up a room especially to show the various applications of electricity for domestic purposes. The room is situate near the High Level entrance, and adjoins the stand of *The Electrician* Company. Mr. H. J. Dowsing acts as demonstrator, and explains to the public visiting the room the advantages of the domestic machinery on view, which consists of small electric pumps, fans for ventilators, spray diffusers, knife cleaners, boot cleaners, coffee grinders, electric kettles, fry-pans, flat-irons, curling tongs, foot-warmers, and other apparatus. The process of cooking by electrical apparatus is shown, including the frying of cutlets, boiling and frying potatoes, and other interesting experiments. A new form of electric heating apparatus is also on view. The apparatus shown is only of small size, but larger apparatus is now being made. There can be no doubt that this additional room will be well patronised by visitors to the Exhibition, and will probably do more to popularise the use of electricity for domestic purposes on what may be termed a small scale than anything else shown at the Crystal Palace. The idea is altogether a good one, and we would offer the suggestion that it be made a permanent exhibit at the Crystal Palace, and also that a similar exhibit be shown at the various Exhibitions held throughout the country; care, of course, being taken to point out that, at any rate for the present, such electrical luxuries are only obtainable by those possessing ample means.

PERSONAL.—Mr. L. Alwyn, who was till lately engineer in charge of Messrs. Laing, Wharton and Down's City installation works, has been appointed by the Brush Electrical Engineering Company (Limited) their sole City agent, at 53, Queen Victoria-street, in succession to Messrs. Bate and Webb Watts.

ALUMINIUM.—A note in the *Financial News* of Tuesday announces that an American Aluminium Company has started an experimental plant in Philadelphia, working on the Broadwell patent. As is usual where aluminium is the subject, all sorts of wild statements are made by the representatives of the Company, the wildest probably being that under this system aluminium can be produced at a halfpenny per pound with profit. Our readers may remember that some time back a man named Mason, trading under the style of the Aluminium Electric Company (amongst others), of Great Sutton-street, Clerkenwell, E.C., issued a circular, bearing all the evidence of genuineness, announcing that the Company with which he was associated was able to manufacture aluminium at 2s. per pound. This gentleman has just been relegated to one of Her Majesty's gaols for 18 months with hard labour for swindles in connection with this and other electrical matters. A weekly paper, reporting his trial at the Clerkenwell Sessions, says that he was indicted for having obtained under false pretences "a carsaw volt-meter and a gravity animator" from one firm, "three animators" from another, besides other curious instruments.

THE PARA RUBBER MARKET.—The following is from the *Financial News*, March 5:—"The rubber market is again advancing. Fine Para, which has recently been bought by dealers at 2s. 8d. per lb., less 2½ per cent. discount for cash, was yesterday quoted at 2s. 10d. for spot and 2s. 10½d. for April delivery. May arrival is not offered, though we understand that large orders are in the market at 2s. 11¼d. Para cables of yesterday quote fine at 2s. 11¼d. delivered in Liverpool, while the American Market sympathises, prices being now quoted at 71c. to 72c. per lb. America has been a large buyer of Para sorts during January and February, which has reduced supplies all round. The new crop of Para rubber does not begin to come in, even in small quantities, until August; and it is generally said that prices, especially in the case of fine Para, will probably experience an advance. Baron Vianna's holdings are said to have been disposed of, and are consequently no longer a dead weight on the market."

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

February 11, 1892.

2,646. L. LARRANAGA. London. Improvements in telephonic transmitters.

2,652. F. KLOSTERMANN. London. Improved regulator for voltaic arc lamps.

2,653. H. E. LANGLEY. London. Improvements connected with electrically operated coin-freed apparatus.

2,690. H. TIPPING. London. Improvements in electric arc lamps.

2,722. A. L. SHEPARD. London. Improvements in electric switches.

Digitized by Google

2,724. A. GRIMM. London. Improvements in electro-therapeutical apparatus.
2,727. O. IMRAY. London. Improvements in telephone receivers. (F. Gross, Canada.)
2,733. A. PIAT. London. Improvements in and relating to the driving and controlling of riveting, shearing, punching, and other machines by electricity.

February 12, 1892.

2,743. A. S. FIELD. Wimbledon. The application of electricity to a scientific puzzle.
2,744. B. HOFFMAN. Manchester. Improvements in telephonic instruments.
2,748. R. J. CROWLEY. Queenstown. Electro-heliograph suitable for interastral communication.
2,762. W. P. THOMPSON. Liverpool. Improvements in or relating to electrical signal apparatus for indicating the position of railway switches or points. (P. Schwenke, Germany.)
2,775. R. A. P. TAUNTON. London. Improvements in ozonizing or electrifying atmospheric air or other gases.
2,784. J. C. NEWBURN, London. Improvements in or relating to sockets and switches for incandescent lamps.
2,785. J. C. NEWBURN, London. Improvements in incandescent electric lamps. (D. H. Piffard, United States.)
2,791. W. COBB, Junior, and W. D. WILDER, London. An improved time-registering device for electric currents.

February 13, 1892.

2,831. J. OULTON and J. EDMONDSON, Halifax. Improvements in apparatus for the driving of chronometric balances and pendulums for electricity meters.

February 15, 1892.

2,913. G. NAHNSEN. Berlin. Improvements in the electro-metallurgic extraction of zinc.
2,920. J. W. KNAUSE. London. An improved pole for supporting telegraph wires and the like.

February 16, 1892.

2,981. P. A. CRAVEN. Wimbledon. Improvements in electro-medical appliances.
2,992. G. D. BURTON. London. Improvements in systems of electrical distribution of heating currents.
2,996. F. HOYER. Liverpool. An improvement in the construction of electric incandescent lamps.
3,030. H. H. LAKE. London. Improvements in and relating to the lighting of railway vehicles by electricity, and to apparatus therefor. (The Consolidated Car-Heating Company, United States).

February 17, 1892.

3,112. S. Z. DE FERRANTI. London. Improvements in electric meters.
3,113. S. Z. DE FERRANTI. London. Improvements in generating, transmitting and utilising currents of high tension, and in apparatus used for these purposes.
3,114. C. THOMPSON. London. Improvements in electrical primary batteries.
3,120. P. H. BERTRAND. London. Improvements relating to galvano plastics or the electro-deposition of metal.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1891.

2,016. HUTCHINSON. Electrically propelled vehicles.
4,588. MUNRO. Electric lamps.
5,045. SENNETT. Transformer aspirator.
5,318. BOARDMAN and FAIRFAX. Arc lamps.
5,329. BRISTOL. Electric safety lamps.
5,350. HARPER. Electrical dynamo machines.
5,404. CLIFT. Electric, &c., lamps.
5,802. MCGEOCH (W. and A. J.). Incandescent electric lamps.
20,699. THATCHER and DEVEREUX. Electric indicator.
2,785. PYKE and HARRIS. Dynamo electric machines.
3,748. MCLEAN. Electrical insulators.
4,660. HOWARD. Heating and welding by electric arc.
5,712. PITT (Davidson). Insulating electrical conductors.
5,713. PITT (Davidson). Insulating electrical conductors.
5,714. PITT (Davidson). Insulating electrical conductors.
5,835. JONES. Electrical measuring instruments.
5,918. HARRIS and POWER. Electric batteries.
6,372. PARLEY. Electric time calls.
12,982. WETHERFIELD. Electric time check.
13,912. PARKER and OTHERS. Electric circuits.
18,493. ELKINGTON. (Compania Electricista contra Incendios.) Electric fire alarms.
18,348. PARKER and OTHERS. Distribution of electricity.
21,728. WATERHOUSE. Electric arc lamps.
22,482. LAKE (Weston.) Voltaic cells.
22,820. FURTADO and OTHERS. Telephones.

1892.

106. STURGE. Electric switches.

COMPANIES' MEETINGS & REPORTS.

Kensington and Knightsbridge Electric Lighting Company (Limited).

The general meeting of this Company was held yesterday, at No. 1, Great George-street, Westminster; Mr. Granville R. Ryder, presiding.

The SECRETARY (Mr. R. S. Erskine) read the notice convening the meeting and the minutes of the previous meeting, which were confirmed and signed as correct.

The report and statement of accounts were taken as read.

The CHAIRMAN said: Gentlemen, as this is a very small meeting I do not think that it is necessary for me to trouble you with many remarks. It will be seen that the Company has made very substantial progress. During the year we have jumped from having 25,535 lamps to 38,408, or an increase of 12,873. During the year the number of houses and shops connected with the system has increased from 291 on December 31, 1890, to 436 on December 31, 1891. With regard to the accounts you will observe that during last year there has been an increase in capital account of £21,780, namely, £13,350, in Preference shares, and £7,930 in Four and a-Half per Cent. Debentures. This increase of capital has been laid out in this way:—in mains and improvements of mains, £8,000; in plant, £7,508; in batteries, £4,200; in instruments and meters, £1,200; and in buildings, £1,000. With regard to the renewal fund, that stood last year at £1,398 odd, and it has been increased this year to £1,713. A satisfactory feature in the accounts is that the production of electricity, which last year cost £2,915, is this year £4,067; and whereas last year with nearly £3,000 spent on its production it only produced a profit of £1,404, this year with an increase of only about £1,000 we have increased our profit to £4,381. Therefore the increased cost has been one-fourth and the increase of profit two-thirds. I think, gentlemen, we may fairly say that, taking the accounts generally, they are satisfactory. We could have wished that we had had more business. That is the only point which is rather disappointing. We expected to get out 40,000 lamps, whereas we have only reached 38,400. Since the latter figure was reached the number has increased by 1,000, but still we have not reached 40,000. What is quite clear from these figures is that there is a very good future for the Company in respect of profits. This is exemplified by figures which Mr. Erskine has worked out for me, showing that the price of the unit we charge is 8d., but it only cost us this year 5½d., leaving a profit of 2½d.; whereas last year the cost was 6½d. out of the 8d., so that we have got the advantage of 1d. out of every 8d. as compared with the preceding year. There is one other point which I should mention, and that is with regard to the gross revenue to be derived from each lamp. Last year I was able to put it at 10s., but we find now that it is not so much as that, being not more than 9s. per lamp. I do not think that we need be dissatisfied with the result, because everything that tends to cheapen the electric light is for our interest and advantage, for it is much more likely that the electric light will become the light of the future if it can be cheapened in every possible way. With regard to capital account it is the object of the Directors to keep it down as much as possible. At the same time in a Company of this kind it is impossible to progress without constantly getting more capital. The only thing to be observed is to see that it is employed in such a way as to yield us a profit. As far as the current year is concerned the capital expenditure will be about £16,000. He concluded by moving the adoption of the report and accounts.

Mr. G. H. HOPKINSON seconded the motion.

The CHAIRMAN, in reply to questions by shareholders, said that the form of their accounts was prescribed by their auditors. He thought that they had made a very good start. In a business of this kind they could not expect to jump into a dividend-paying position all at once. They had no doubt advanced rather slowly last year, but every day there were fresh installations for houses and shops coming in. He did not think that the salaries paid to their staff were too high, considering that they had two branches which had to be conducted by scientific men.

Referring to the action "Lane Fox *v.* The Kensington and Knightsbridge Electric Lighting Company, Limited," Mr. R. W. WALLACE stated, in order to allay any fears shareholders might have as to the ultimate cost of the action, that this would be borne only partly by this Company.

The motion was then agreed to.

The CHAIRMAN next moved the payment of a dividend on the ordinary shares at the rate of 2 per cent. for the year.

Mr. R. W. WALLACE seconded the motion, which was agreed to *nem. con.*

Mr. A. S. Bolton and Sir Frederick J. Bramwell, Bart., were unanimously re-elected to their seats at the Board. The latter, in returning thanks, wished to remind any shareholders who might think that the salaries paid by the Company to its staff were too high, that the business they were pursuing was one of great difficulty, requiring the greatest care and men of ability and trustworthiness. Considering the services rendered, he thought that the salaries were extremely small indeed. As a Director he was quite content to go without his fees until the Company could afford to pay them, but he was not content to employ men of ability and not adequately remunerate them.

The auditors, Messrs. Lovelock, H. W. Whiffin and Dickinson, were unanimously re-appointed.

Digitized by Google

On the motion of Mr. SCHWAN, seconded by a SHAREHOLDER, a vote of thanks to the Chairman and Directors was cordially passed.

The CHAIRMAN, having briefly expressed his acknowledgments, the proceedings terminated.

The following is the report of the Directors for the period ending December 31, 1891, presented at the above meeting :—

The Company's mains, which extended for a length of 10 miles in the previous year, have been increased during the year 1891 to 12½ miles. During the year the number of houses and shops connected with the system has increased from 291 on the 31st December, 1890, to 436 on the 31st December, 1891 ; while the number of lamps, calculated on the usual basis of eight c.p., has increased from 25,535 to 38,408.

The plant at the stations has been worked at a greatly increased rate of efficiency, especially during the last half-year, and further improvement in this respect is still being made. Provision has been made at Kensington Court for fixing a new boiler, and at Chapel-place three new engines have been added during the year to meet the rapid increase in the demand at this station. The funds required by the Company for extensions during the past year have been raised by the issue of Four and a-Half per Cent. Debentures, and it has not been found necessary to issue any of the Second Preference Shares authorised at the last Meeting.

The dividend on the Six per Cent. Preference Shares was duly paid to 30th June, 1891, and out of the balance standing to the credit of the net revenue for the year 1891, £3,810. 11s. 3d., the sum of £1,462. 10s. has been appropriated for the payment of the Preference dividend to that date, leaving £2,348. 1s. 3d., out of which it is proposed to pay a dividend on the ordinary shares at the rate of 2 per cent. for the year, carrying forward £848. 1s. 3d. to the next account.

In accordance with the Articles of Association, Mr. A. S. Bolton and Sir Frederick J. Bramwell, Bart., F.R.S., retire from the Directorship, and, being eligible, offer themselves for re-election. The Auditors, Messrs. Lovelock, H. W. Whiffin and Dickinson, offer themselves for re-election.

Liverpool Electric Supply Company (Limited).

The ninth annual ordinary general meeting of the shareholders of this Company was held on Friday at Liverpool ; Mr. A. H. Holme, Chairman of the Company, presiding.

The report of the Directors on the working for 1891 stated that the amount of net profit available for dividend, including the balance brought forward from last year, was £7,866. 14s. 9d., out of which they recommended payment of a dividend of 4½ per cent. per annum, absorbing £6,580, adding £500 to the reserve fund, and carrying forward the balance to next year's account. They considered the time had arrived when, in addition to writing off depreciation, a provision should be made for the renewal of mains and plant which might be necessary in the future, and they had, therefore, initiated a renewal fund, to the credit of which they had passed a sum of £1,500. The expenditure on capital account during the year (including a proportionate charge for general expenses) had been £17,122. The demand for electricity continued to increase, and the number of lamps connected with the Company's supply mains on December 31, 1891, was equivalent to 14,966 lamps of 16 c.p. each. During the year Provisional Orders had been granted to the Company by the Board of Trade for an additional area in Liverpool, including London-road, Prince's-road, and Prince's Park, and also for an area under the Toxteth Park Local Authority, including Sefton Park and the adjacent residential district. Both these Provisional Orders were for the full statutory term of 42 years. The Directors had obtained the consent of the Watch Committee, subject to confirmation by the City Council, to a Provisional Order under which the date for compulsory purchase on the terms of the Electric Lighting Acts of the Company's undertaking authorised by the Provisional Order of 1889 was postponed from 21 to 42 years ; the Corporation to have the option of taking over the Company's supply business in the City of Liverpool as a going concern after December 31, 1897, at a price to be fixed by arbitration, as in the case of property taken under the Lands Clauses Consolidation Acts.

The CHAIRMAN, in proposing the adoption of the report and balance-sheet, proceeded to explain the position of the Company in further detail. He first observed that their business had since the previous year very materially increased, and that their prospects also were exceedingly good. People were beginning to appreciate the electric light, and he was glad to say that with increasing business they had made increased profits. The dividend proposed had been fairly earned. Some shareholders might say that they should have declared a dividend of 5 per cent., but they were anxious to do nothing which would injure the future of the Company. With regard to the renewal fund, it was certain that the wires did deteriorate to some extent, although not through the passage of electricity ; and, besides that, the advance of electric science might make necessary improvements which at present they could not foresee. The expenditure on capital account was due more particularly to the extension along Rodney-street and Mount-pleasant, and it had been fully justified. Last year the number of lamps was 11,750 ; this year the number was 14,966 ; and at present they had orders which would increase the total to 16,900, which was, he thought, very satisfactory. As to the Provisional Order for the additional area, it was for that area that they were making a call of 10s. a share. That would bring in £17,000, which would be nearly all absorbed in an extension proceeding in one direction through Abercrombie-square and along Bedford-street to Prince's-road, and in the other towards University College and London-road. In all those districts they had considerable promises from people anxious to use their light, and he thought that next year the shareholders would say that the expenditure was justifiable. He came next to a matter of great importance, and one which had cost the Directors some anxiety. After somewhat protracted negotiations with the Corporation through the Watch Committee, they had come to an arrangement, which, the previous day, was confirmed by the Council, in consequence of which the shareholders might consider that for 42 years their undertaking was their own property, and could not be taken over by the Corporation except on terms which were satisfactory to the Company, and would give them a fair return for the money they had expended. It was one of those happy agreements by which everyone benefited mutually, for by it their consumers got electricity at a much lower price than they could have obtained it otherwise. In various matters the Corporation were really very hard people to deal with. They had made the Company pay a large sum for reinstating the streets. He hoped, however, that the Corporation would follow the example of other cities. In Manchester, Birmingham, London, and even in Bootle, town halls and public buildings were lighted by electricity, and it was to some extent scandalous that the Liverpool Town Hall should continue to be lighted by gas. At the same time, the Corporation had instructed their engineer to report on the matter, and no doubt the effect would be that the Company would increase its business to that extent.

Mr. D. DE YBARRONDO seconded the motion.

In reply to questions, the CHAIRMAN said the dividend would be paid free of income-tax. The patent for the lamps expired next year, and they would then be produced for about 1s. 3d. a piece, instead of from 4s. to 5s. as at present. The arrangement with the Corporation was that all profits over 7 per cent. were to be divided equally between the shareholders and consumers.

The report having been passed, and the retiring Directors, Messrs. A. H. Holme and D. de Ybarrondo, and the auditor, Mr. W. L. Jackson, re-elected, it was decided to increase the remuneration of the Directors from £300 to 400 guineas.

The CHAIRMAN afterwards submitted a resolution approving of the Provisional Order now being promoted by the Company before the Board of Trade, and accepting the amendments agreed upon between the Company and the Corporation, which was seconded by Sir D. RADCLIFFE, and agreed to.

A vote of thanks to the Chairman concluded the proceedings.

Taunton Electric Lighting Company (Limited).

The fifth annual general meeting of the shareholders of this Company was held on the 29th ult. at Taunton ; Mr. W. H. Fowler, Chairman of the Company, presided.

The CHAIRMAN, in moving the adoption of the balance-sheet, expressed great regret at meeting the shareholders under such unfavourable circumstances. He had to report a deficit. He attributed it mainly to the fact that the public had not supported the Company to the extent which the Directors had been led to expect would have been the case when they removed to the larger depôt. The system adopted by the Company of charging the consumers so much per lamp instead of by meter had not been successful. As the consumers paid a certain sum per lamp, however long they burnt it, they were not so economical as they would be if they paid by meter ; and also the system of charging which was adopted was not satisfactory to the consumers, for they paid for the light whether they used it or not. It was known that some consumers used the electric light for much longer hours than they would if they had gas.

Mr. POTTER seconded the motion for the adoption of the balance-sheet, and it was carried.

The retiring Directors, Messrs. Bale, A. Chapman, and W. Potter, having been re-elected, the question of the disposal of the works to the Town Council was brought up ; but the matter was left entirely to the Directors to do the best they could for the shareholders. Complete confidence was expressed in the Directors, to whom a vote of thanks was accorded for pa t services.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed p r-ticulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, pages 308-322, *and in other parts of that book.*]

BOARDMAN'S ELECTRIC SUN LAMP PATENTS (LIMITED).—This Company was registered on March 5, 1892, with a capital of £10,000, in £5 shares, by C. E. Baker, 22, Great George-street, Westminster, S.W. The objects are to carry on the business of an electric light, power, and manufacturing company in all its branches ; to apply for, purchase, or otherwise acquire, patent rights and privileges relating to patent rights connected with the use of electric light, power, or force ; to enter into contracts for the supply of electric power for lighting, locomotion, electro-plating, or deposition, or any other purpose ; and to carry on the business of manufacturers of, and dealers in, all or any kinds of electrical apparatus and appliances, whether used or to be used in connection with electric lighting, locomotion, or other purposes. Registered without Articles of Association.

HOBART TRAMWAY COMPANY (LIMITED).—This Company was registered on March 4, 1892, with a capital of £105,000, in £1 shares, by Messrs. Linklater, Hackwood, Addison, and Brown, 2, Bond-court, Walbrook, E.C. The objects are to apply for, obtain, accept, adopt, and carry into effect any Act of Parliament, Imperial or Colonial, Provisional Order, concession, or contract for the establishment, construction, maintenance, and working of tramways in Hobart, Tasmania, or elsewhere : to take over the existing tramway at Hobart ; to construct, equip, maintain, and work, by means of electricity or in any other manner, any tramways; to carry

Digitized by Google

on at Hobart, or in any part of Tasmania and elsewhere, the business of an electric light company in all its branches, and in particular to form centres at which electric power may be generated and accumulated, and from which the same may be distributed by means of wires or other conductors of electricity, for the purpose of lighting public buildings, houses, streets, &c.; to enter into contracts for any period for the supply of electric force, and to supply, fix, and maintain all electric generators, batteries (primary or secondary), lamps, engines, motors, converters, meters, and other electric appliances. (The tramways to be taken over are authorised by special Act of Parliament of Tasmania, 48 Vic., as amended by 53 Vic. and 55 Vic., and it is proposed to work them by electricity by means of overhead conductors.) The number of Directors is not to be less than one nor more than seven, the first being Sir Edward N. C. Braddon, K.C.M.G., Agent-General of Tasmania (Chairman), Charles Barclay, Alfred Mattei, LL.D., J. C. Bellamy, J. W. Syme, and C. H. Grant, M.I.C.E. Qualification, the holding of 100 £1 shares. Remuneration: £100 per annum for each Director, and £50 additional per annum for the Chairman. In addition to the above, whenever a 10 per cent. dividend has been paid, the Directors are entitled to 5 per cent. of the net profits above the said 10 per cent. Offices: College Hill-chambers, Cannon-street, London, E.C. [Further reference is made to this Company in "City Notes"]

NEWALL AND COMPANY (LIMITED).—This Company was registered on the 4th inst., with a capital of £10,000 in £10 shares, with objects, among others, to carry on the business of mechanical, marine, gas, and electrical engineers, machine and engineering tool makers, manufacturers of locomotive, traction and other engines, boiler makers, &c.

MISCELLANEOUS COMPANIES.—The following Companies, proposing to deal more or less with electricity, have been registered:—

Birmingham Art Metal Company (Limited); capital £5,000.
Leen Valley Land Company (Limited); capital £1,000.
Willoughby and Co. (Limited); capital £2,000.

ANDREWS AND PREECE (LIMITED).—The first annual return of the above-named Company made up to December 31, 1891, was filed on February 22, 1892. The Company was registered on April 1, 1890 with a capital of £25,000, divided into 300 deferred and 22,000 ordinary shares. At the time of making up 300 deferred and 408 ordinary shares had been taken up, of which the deferred shares had been issued as fully paid. Upon the 408 ordinary shares the full amount had been called, resulting in the payment of £4,015, and leaving £65 in arrears. The second return of the same Company, made up to February 11, 1892, was also filed on February 22. No change has been made. The principal shareholders are Thomas R. Andrews, with 200 deferred and 187 ordinary shares, and Thomas Preece, with 100 deferred and 46 ordinary shares.

CARBON ELECTRIC (LIMITED).—The registered offices of the above-named Company have been removed from 24, Moorgate-street, London, E.C., to 33, Old Broad-street, London, E.C. This Company was registered on April 15, 1891, with a capital of £20,000, in 4,000 shares of £5 each (of which 3,000 were Preference and 1,000 Deferred. No statutory return has been filed (although such return ought to be filed within five months of registration), and no agreements for the purchase of the works alluded to above, or any other, have been filed.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).- The annual return of the above-named Company, made up to February 24, 1892 was filed on March 4, 1892. The Company has a nominal capital of £220,000, divided into 16,000 Ordinary and 6,000 Preference shares of £10 each, of which all have been taken up, the full amount called, and all calls (£220,000) paid.

BRITISH INSULATED WIRE COMPANY (LIMITED).—The first annual return of the above-named Company, made up to February 24, 1892, was filed on March 5, 1892. The Company was registered on October 20, 1890, with a capital of £60,000, divided into 300 Founders', 3,950 Preference, 3,450 Ordinary A, and 4,300 Ordinary B shares of £5 each. By a special resolution in general meeting, passed June 23, 1891, the capital was raised to £110,000 by the addition of 6,000 Ordinary A shares and 4,000 Ordinary B shares of £5 each. By an agreement made August 7, 1891, with S. Z. de Ferranti, it was agreed that the vendor should sell and the Company should purchase the following patents:—No. 12,505, of 1888, for joints in electric mains; No. 16,237, of 1889, for improvements in electric mains; No. 2,315, of 1888, for improvements in electric mains; No. 15,251 of 1885, for improved means for distributing electric energy; and No. 12,418 of 1887, for carrying electric energy: subject, however, to an agreement dated August 2, 1887, between Sir Coutts Lindsay and Co. (Limited) and S. Z. de Ferranti, the benefits of which are now vested in the London Electric Supply Corporation (Limited), the vendor only to sell his interest in the last two mentioned patents, and that part only which referred to mains or conductors to be used for carrying electric energy. The consideration for the said sale was to be the sum of £26,305, to be satisfied as follows, viz.:—£6,210 in cash, and the balance by the issue, to the vendor or his nominees, 475 Preference, numbered 2,826 to 3,300 inclusive, 475 Ordinary A, numbered 7,001 to 7,475 inclusive, 3,050 Ordinary B shares, numbered 16,001 to 19,050 inclusive, and 19 Founders' shares, numbered 282 to 300 inclusive. At the time of making up (February 24, 1892), 16,522 shares had been taken up. Upon 300 Founders', 3,250 Preference, 2,552 Ordinary A, and 7,018 Ordinary B shares, the full amount has been called, and upon 400 Preference, and 3,002 Ordinary A shares, £1. 5s. has been called, resulting in the payment of £69,015, and leaving £837. 10s. in arrears. The principal shareholders are:—W. M. Brigg, of Keighley (51 Founders', 539 Preference, 299 Ordinary A, and 1,109 Ordinary B), Messrs. Felten and Guilleaume, of Mulheim-Rhine, Germany (20 Founders', 500 Preference, and 1,000 Ordinary A), and Sebastian Z. de Ferranti, of Charterhouse-square, London (75 Founders', 275 Preference, 175 Ordinary A, and 3,550 Ordinary B shares).

ELECTRIC TRAM CAR SYNDICATE (LIMITED).—The annual return of the above-named Company was made up to and filed on January 12, 1892. The Company was registered on April 26, 1889, with a capital of £20,000, in £10 shares. At the time of making up, 1,814 shares had been taken up, of which 1,300 had been issued as fully paid, in accordance with the above agreement. Upon the remaining 514 the full amount had been called, resulting in the payment of £5,130, and leaving £10 unpaid. The following notice was filed on March 2, 1892. At a special general meeting of the members of the above-named Company, duly convened, and held at 31, Lombard-street, E.C., on February 11, 1892, the following special resolutions were passed, and at a subsequent special general meeting were confirmed:—"1. That the capital of the Company be increased to £25,000 by the creation of 500 new ordinary shares of £10 each." "2. That the Directors be and are hereby authorised to issue the said 500 shares to such persons, and to be paid for by such instalments, or otherwise, as they think fit, and without being bound to offer the same, or any of them, to existing members of the Company." The legal forms for the increase of capital referred to above were also filed on March 2, 1892.

WEYMERSCH ELECTRIC BATTERY SYNDICATE (LIMITED).—The first annual return of the above-named Company, made up to February 11, 1892, was filed on the following day. The Company was registered on November 28, 1890, with a capital of £20,000 in £5 shares. At the time of making-up, 3,807 shares had been taken up, of which 300 had been issued as fully paid. Upon 200 of the remainder the full amount has been called, and upon 600 £4 per share has been called, while upon the remaining seven, no calls have been made. The total paid amounts to £2,800.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED). — An interim dividend has been declared of 3s. per share, being at the rate of 6 per cent. per annum, free of income tax, for the quarter ended December 31, 1891, payable on the 25th inst. The books of the Company will be closed from the 18th to 24th inst. inclusive.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).— The traffic receipts for the week ended March 6th were £893, as against £732 in the corresponding period of last year, showing an increase of £161. The total receipts to date, from January 1st, 1892, are £7,954, against £6,965, an increase of £989.

COMMERCIAL CABLE COMPANY.—This Company announces the payment on April 1st of the quarterly dividend at the rate of 7 per cent. per annum.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).— The receipts of this Company for the month of February amounted to £1,865, as compared with £1,953 in the corresponding period of last year, a decrease of £88.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment on the 14th April next of interest of 3s. per share, less income tax, being at the rate of 6 per cent. per annum on the Preference shares of the Company for the quarter ending March 31st; and the usual interim dividend of 2s. 6d. per share on the ordinary shares, free of income tax, in respect of profits for the quarter ended December 31st last. The register of transfers will be closed from the 7th to 14th April, both days inclusive.

"ESTON" ARC LAMP SYNDICATE (LIMITED).—The prospectus is issued of this Syndicate, which is formed with a capital of £25,000, divided into 5,000 shares of £5 each; payable, £1 on application, £2 on allotment, and the balance at not less than one month's notice. The first issue is for 2,200 shares at par. Amongst the Directors is Mr. George North, A.I.E.E.; the consulting engineer is Mr. James Swinburne; the secretary is Mr. T. H. Robinson; and the offices (*pro tem.*) are situated at 26, Thavies'-inn, Holborn, E.C. The Syndicate is formed to acquire the patent rights for England and the chief cities of the Continent, Canada, and the United States in the "Eston" arc lamp, for which thorough efficiency is claimed and on behalf of which a very satisfactory report is made by Mr. C. E. Spagnoletti, who concludes his report by saying, "I consider it one of the best and cheapest arc lamps in the market." The price paid for patents is £15,000, payable as to £6,000 in cash, and £9,000 in shares, this sum to include all expenses for the registering and floating of the Syndicate. Bankers: The City Bank, Holborn-viaduct, E.C.

GREAT NORTHERN TELEGRAPH COMPANY (LIMITED).—The traffic returns of this Company in February, 1892, were £20,800; 1st January to 29th February, 1892, £40,800; corresponding month, 1891, £41,600; 1890, £39,400.

HOBART TRAMWAY COMPANY (LIMITED).—The prospectus of this Company was issued early this week. The authorised share capital is £105,000 in £1 shares, of which the current issue is for 60,000 shares, 45,000 shares being held in reserve for the debenture holders. The trustees for the debenture holders are the London and Australasian Debenture Corporation (Limited); the consulting engineer is Sir Benjamin Baker, K.C.M.G.; the contractors for electric plant are Messrs. Siemens, Brothers and Co. (Limited); the secretary is Mr. G. Carnaby Harrower, C.A.; and the offices of the Company are at College Hill-chambers, Cannon-street, London, E.C. The object of the Company is to acquire the Hobart Tramways and to equip the same by electric power. Various calculations are made, with the result that a possible revenue of £25,555 is produced The

Digitized by Google

tramway will be worked by overhead conductors, and the necessary work, are the Directors believe, within the powers conferred by the Act of Parliament regulating the district. Messrs. Siemens Brothers and Co. have contracted to equip the line with 20 cars, and the electrical fittings and accessories, for the sum of £33,000, and to complete the line by December 31, 1892; and they have also agreed to work the line for twelvemonths at 4d. per car mile. It is intended to apply to the local authorities of Hobart for powers to light by electricity the streets, &c., and to supply power for general purposes. We must refer our readers to the prospectus for further details. The list opened on Monday, and closed on Wednesday last.

ORIENTAL TELEPHONE COMPANY (LIMITED).—The Directors of this Company have resolved, subject to audit, to recommend to the shareholders a dividend at the rate of 2½ per cent. on the entire paid up capital of the Company, which dividend being only payable to the holders of ordinary shares, is equivalent to £3. 12s. 2d. per cent. on each share of 11s. paid. This is the same dividend as was paid last year.

PIONEER TELEPHONE COMPANY (LIMITED).—The Press are informed that letters of allotment in this Company have been posted.

WESTERN UNION TELEGRAPH COMPANY.—This Company has declared the usual quarterly dividend of 1½ per cent.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the month of February amounted to £2,685, as compared with £2,563 in the corresponding period of last year, an increase of £122.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 722.—Vol. XXVIII. FRIDAY, MARCH 18, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

Misfortunes never come singly; and, if there are any misfortunes about, the London Electric Supply Corporation is sure to come in for its share. At about two o'clock on Thursday afternoon last week a fire broke out in a store of cotton waste, oils and refuse, under one of the arches of the South-Eastern Railway near Spa-road. The four Ferranti mains from Deptford run along the parapet just over the arch, one above the other. The upper one was alone in use at the time. The first warning was a blink in the lights. A few minutes afterwards the voltmeter at the office of the Company at Adelphi-terrace went up to 110, and almost immediately afterwards the lights went out. On telephoning to Deptford to inquire for the cause, it was understood that the first main had gone; the load was shifted to another, and in a few moments the same events were repeated, and the officers of the Company learned that the whole of their communication with Deptford was interrupted. At Deptford considerable sparking occurred on the dynamos, and continued until the fuses went. The injury to the machines was not serious, and has been repaired.

One of the employés happened to pass the scene of the fire on his way to Deptford, and finding that the generators had been shut down, suggested the fire as the cause of the breakdown. A gang was immediately sent off, and succeeded in establishing a temporary communication by 11 o'clock in the evening, and new lengths of Ferranti mains were laid in the course of Friday. The London Electric Supply Corporation warned as many of their customers as they could in the course of Thursday afternoon that the light could not be supplied that evening, but very considerable inconvenience was naturally felt. The misfortune was of so purely an accidental character that no blame could possibly be attached either to the Company or the system which it employs. Storage batteries and continuous current would not have mitigated the effect; while if electric lighting as a whole be blamed, it must be remembered that had gas mains, instead of Ferranti mains, been attacked by the fire, the disaster would have been enormous.

The Ferranti mains have been rigorously tested to ascertain what temperature they will withstand, and on first hearing of this fire, it might have been thought that nothing short of a collapse of the archway would have injured them. We learn, however, that the flames were so intense that the outer iron tube was burned away, as well as the outer copper conductor, and that long lengths of the main were split, curled, and twisted. The insulation between the inner and outer conductors blazed violently, until a short circuit occurred. The London Electric Supply Corporation were not the only sufferers; the flames also destroyed the London and Paris telephone wires on the opposite side of the road which runs along side the arches and interrupted the railway traffic.

The experiments which are arranged by Messrs. Siemens Bros. as a sixpenny side-show at the Crystal Palace are well worth seeing, even by those who were present at the lectures of Mr. Nikola Tesla and Messrs. Bourne. Among the experiments, which are repetitions of those of Mr. Tesla, is that of the two concentric rings of wire. The radial discharge is comparatively feeble; but attention has been drawn to a number of small brilliant points on the wires, and it has been suggested that these are nodes of longitudinal vibrations. On the occasion on which we witnessed this experiment, the rings were roughly made of wire; but the disposition of the bright points, if really due to nodes, should have been spaced at perfectly regular, though perhaps not equal distances. This was not the case, and the irregularities were certainly due to something more than the crookedness of the wire, both in the outer and the inner ring.

The experiment of Dr. Oliver Lodge at the Physical Society, to which we alluded when commenting on Mr. Tesla's experiments, consisted of a pair of ordinary Leyden jars and a circuit of bare copper wire,, about 60ft. long. This acted as a stopped organ pipe, the remote end, which was insulated, being a node at which the variation of pressure was the greatest. Dr. Lodge described experiments with much longer wires, in which complete waves of the higher harmonics were visible. There was a gradual increase and a gradual decrease of brilliancy along the wire, exactly like the varying amplitude of vibration of a stretched string; but the spark-like points of light on Messrs. Siemens' wire were set at about five or six to the inch, if we remember rightly. The smallest wave length that Dr. Lodge has been able to produce has been about six centimetres, and the capacity in the circuit was only a metal ball of about six centimetres diameter. The condenser at the Crystal Palace was a large affair, composed of a roll of india-rubber sheet

Digitized by Google

with a conductor plate coiled up in it. We see no reason to suppose that these points of light were due to high harmonics, and are inclined to think that if quarter-inch waves are to be produced, the whole condenser and circuit would have to be small enough to go easily in a waistcoat pocket.

It is as well that the battle royal which has recently taken place within the Institute of Chemistry should be brought to the notice of electrical engineers. As is so frequently the case, the members of the Institute had drifted into the vicious habit of submissively voting year after year for official nominees, with the inevitable result that they woke up one fine day to find that the Council no longer accurately represented its electors.

So far as we can gather, the main cause of the disturbance was the alleged undue proportion of professors on the Council, and the consequent exaltation of technical training. Pupilage, pure and simple, was in danger. Hence these tears! The opposition to the "techniker" does not originate here more than elsewhere solely from a dislike of that young gentleman's admitted defects; and those who wish to live in peace and charity with the veterans of chemistry must take Bacon's advice to heart, and innovate "by degrees scarce to be perceived."

The attack, although a failure so far as the election of Council was concerned, will have the effect of reminding the leading lights of the Institute of Chemistry that there are two sides to every question, a result in itself of no little value. May we take the election of a member of the Institution of Electrical Engineers to the important post of registrar and secretary as an indication of a new movement to bring the Institute into closer contact, not only with its own members, but with the members of the many professions to which Chemistry is, or should be, allied? It is a commonplace to say that chemists and electrical engineers can afford each other considerable assistance; but do they? Take, for example, the breaking-down of insulators by the prolonged application of high-alternating potentials; neither the freaks of dielectrics nor the vagaries of secondary batteries can be explained on purely mechanical grounds. Minute chemical changes, which escape the eye of an electrical engineer with a dash of the chemist in his composition, might well be detected by a skilled chemist. Why not appoint a joint Committee of Investigation?

The meeting held at the Mansion House on Friday last to consider the Chicago Exhibition, although largely attended, was of a somewhat disappointing character. The voice of the manufacturer was not heard in the land, but in place thereof we were treated to a series of mingled appeals to patriotism and pocket. *Facile princeps* should indeed be our motto everywhere, and especially in the United States of America. But to express an admirable sentiment is one thing, to pay for it oneself is quite another. If exhibiting at Chicago is a mere matter of patriotism, the cost of the patriotic display should not fall entirely upon one section of the community; the Government grant should have been such as to permit of the tax upon exhibitors being reduced to a minimum, if not entirely done away with. On the other hand, if it is as the speakers on Friday almost without exception asserted, of vital importance to Great Britain's commercial supremacy that she should be adequately represented at Chicago, then what are we to think of those who accepted the onerous and thankless duties of Royal Commissioners with but £25,000 at their back? If the commercial supremacy of the World is in reality the guerdon, £25,000, plus the enlightened self-interest of a few individual firms, are surely not equal to the gravity of the occasion.

Great stress was laid upon the understanding—not promise, be it noted—that foreign exhibitors would be allowed to label their wares with placards setting forth in bold type their selling prices with and without the McKinley Tariff. To allow the World's Fair Columbian Exposition to be converted into a hostile demonstration against Protection would be an unparalleled act of magnanimity on the part of the American nation and a strange piece of political folly on the part of the Republicans. Before foreigners exhibit on the strength of this "understanding," an Act of Congress would seem desirable. *Timemus Americanos et dona ferentes.*

The office and duties of scrutineer at the meetings of the Institution of Electrical Engineers are not arduous, as the President has observed on several occasions; but there is a general desire to avoid catching his eye when the appointment has to be made, especially when, as on Thursday, last week, experiments were about to be performed. We venture to suggest that the selection be made from among those members whose subscriptions are in arrear.

Erfurt.—The Gas Company at Erfurt is about to undertake the supply of electricity.

Cannstadt.—It is proposed to light this town by electricity. Power would probably be derived from the River Neckar.

Tuttlingen.—The Town Council of Tuttlingen has the intention of adopting the electric light. Water-power to the amount of 500 H.P. is available.

Electric Light Cables.—The first line of the second paragraph of Mr. Connolly's letter last week should read "The separator should consist of a non-vulcanised rubber compound."

Electric Traction in Wurtemburg.—The first electric railway in Wurtemburg, between the Baienfurt paper mills and the station at Ravensburg, a distance of over two miles, has just been opened.

Halle.—The gross receipts of the tramway at Halle for last year (during the latter part of which electricity was adopted) amounted to about £9,600, being £2,350 in excess of those for the previous year.

Electricity Applied to Mining.—A Paper on "Electricity Applied to Mining," by Mr. Llewelyn B. Atkinson, was read at the last meeting of the South Staffordshire and East Worcestershire Institute of Mining Engineers.

Cooking by Electricity.—Experiments in cooking by electricity were made in Wallace's Restaurant, Neville-street, Newcastle, last week, under the auspices of the Newcastle and District Electric Light Company.

Digitized by Google

Royal Society.—The following Papers were down for reading yesterday before the Royal Society:—Dr. Hopkinson, F.R.S, and E. Wilson, "Dynamo-Electric Machinery;" Mr. R. T. Glazebrook, F.R.S., and Mr. S. Skinner, "On the Clark Cell as a Standard of Electromotive Force."

Glasgow.—At a Dean of Guild Court held on Thursday last week plans were submitted by the Lord Provost, magistrates, and Town Council of Glasgow of buildings which they propose to erect at the corner of Wellington-street and Mains-street. The plans, which were those of the Corporation's new electric lighting station, were passed.

The C.S.P. System of Concentric Wiring.—In the description on p. 489 of our last issue of a new and ingenious system of concentric wiring we omitted to mention that Mr. David Cook, General Manager to the City of London Electric Lighting Company, was a joint inventor of it, together with Mr. Carrington Smythe and Mr. Ernest Payne.

The Cost of Lighting the House of Commons.—For the coming financial year the electric light bill of the House of Commons is estimated at £1,800; the gas bill at £3,200; while the bill for oil lamps will not exceed £1,550—a total of £6,550. Taking the Board of Trade unit at 7d., an £1,800 bill would mean that no less than 61,000 units are likely to be consumed.

Institution of Electrical Engineers.—A students' meeting was held at the library of the Institution on Friday, the 11th, Prof. George Forbes, F.R.S., presiding. Messrs. Drysdale and Poore read a Paper on "Electric Welding," which was illustrated by photographs projected on to a screen, as well as by specimens of welds made by this process. On the 25th inst. Mr. C. A. Gawthorp will read a paper on "Measurements of Power in Alternate Current Circuits."

Lectures.—The Saturday Art and Science Lecture at the South Kensington Museum was delivered by Mr. C. V. Boys, on "Electric Spark Photography as applied to flying Bullets and other rapidly moving Bodies."——A lecture to the Insurance Institute of Manchester on "The Fire Risks of Electric Lighting" was given on Thursday evening last week at the Electrical Engineering Branch of the Manchester Technical School by Mr. Haldane Gee, chief lecturer in electrical engineering.

Institute of Chemistry.—At the annual general meeting of the Institute of Chemistry, held recently, the officers elected were as follows:—President, Dr. W. A. Tilden, F.R.S. Vice-Presidents: Dr. James Bell, C.B, F.R.S.; Mr. M. Carteighe, F.C.S.; Dr. E. Frankland, F.R.S.; Mr. Charles E. Groves, F.R.S.; Dr. W. Ramsay, F.R.S.; Dr. J. Emerson Reynolds, F.R.S. Treasurer: Mr. David Howard, F.C.S. Mr. G. H. Robertson, F.C.S., A.I.C., A.I.E.E., was appointed Secretary and Registrar, in succession to Mr. Charles E. Groves, F.R.S.

Festiniog Local Board.—At the last meeting of this Board the Gas Committee suggested either an expenditure of a large amount to put the present gasworks in proper working order, or that the works should be done away with and electricity substituted. After some discussion it was ultimately agreed that the Bangor Gasworks manager should be asked to examine and report on the gasworks, and give his estimate; and also that an electrical engineer should be asked to report on the electric lighting of the district, both reports and estimates to be considered at the next meeting.

Taunton.—The Special Committee of the Town Council appointed to consider the proposed purchase of the Electric Light Works have reported as follows:—"Your Committee report that they have prepared a report on the subject of the Electric Lighting Company's undertaking, which they have ordered to be printed, and three copies to be sent to each of the members of the Town Council; also a copy to each of the local papers. The Committee recommend that a special meeting of the Council be held on Tuesday, March 22nd, at half-past ten in the forenoon, to consider the report."

Worcester.—At the last fortnightly meeting of the Watch Committee, the Town Clerk presented the report of Mr. Preece, who had been consulted by the Committee for the consideration of the electric light tenders. Mr. Preece estimated the annual revenue to be derived from the proposed plant when it was fully taken up, if 6d. per Board of Trade unit be charged, at £10,800, and the total working expenses £5,500, showing a profit of £5,400. The estimated cost of building at the weir was £6,900, but the reduction in the cost of working expenses through the use of water-power fully justified this. He estimated that they would require £40,000 for their undertaking. The Committee decided to recommend that the Brush Company's tender be accepted.

The Electric Transmission of Power at the Thomson-Houston Company's Works. The Thomson-Houston Company's works at Lynn, Massachusetts, having of late years increased so greatly, and the consumption of coal in the works and difficulties of transport having become so great, it has been decided to establish a generating station on the river banks, and to transmit the energy to the works by electricity. For that purpose the Company have bought a plot of land on the River Sangus, and the generating station will be placed at a spot where the vessels can discharge the coal directly. In this way not only will economy of transport be realised and successive transhipments of the coal avoided, but it will also permit of buildings which had become too small being enlarged.

Driving Looms by Electricity.—The City Council of St, Etienne has decided to apply electric power to all the hand-looms in the city, and contracts have been made with an electric company for the necessary plant. The dynamos are to be driven by water from the city reservoirs. There is practically an unlimited supply of water, with a fall of upwards of 100ft. The bulk of the enormous output of ribbons (£4,500,000 a year) is the product of house industry. The weavers for the most part own their own looms, and operate them by hand in their own houses. There are 18,000 looms which are thus distributed among the homes of the weavers, while the number of looms driven by steam in the few ribbon factories of the town is only 5,000. The 18,000 looms of the independent weavers are valued in the aggregate at £900,000.

The Association for the Improvement of Geometrical Teaching.—An important memorial will shortly be brought before the Board of the Faculty of Natural Science, Oxford, by the Council of the Association for the Improvement of Geometrical Teaching. It relates to what the Council regard as a serious defect in the Oxford Pass Examination Papers in geometry. These generally consist entirely of propositions enunciated without any variation from the ordinary text of Euclid, and scarcely any attempt is made to discover whether a student's answers are other than the outcome of a mere effort of memory. The Council are of opinion that such Papers have the effect of a direct incentive to unintelligent teaching, and respectfully ask for the introduction of simple exercises and of simple questions on the book-work set in order to promote the rational study of geometry.

London County Council and Electric Light Mains.—At the meeting of the London County Council on Tuesday, 1st inst., conditional sanction was given to some works of the Notting Hill Electric Lighting Company, and of the House to House Electric Light Supply Company. The St. James and Pall Mall Electric Lighting Company gave notice of intention to lay mains in Coventry-street, Rupert-street, and the west side of Wardour-street. They propose to lay insulated cables in pipes or bitumen conduits, or, where there is found sufficient room, to lay bare copper in Crompton conduits. Conditional sanction was given to the work. Notice was also given by the Electric Installation and Maintenance Company of intention to lay mains for the Crystal Palace District Electric Supply Company. The proposed works were considered objectionable in many respects, and the Council formally disapproved of them.

The Moebius Process.—Mr. B. Moebius, the well-known electro-metallurgist of this city, says the *Engineering and Mining Journal* of New York, has gone to Germany, where he will build an electrolytic parting plant for the *Deutscher Gold und Silber Scheide Anstalt*, at Frankfort-am-Main, the largest concern of its kind on the Continent. We are informed that an officer of this Company was sent over to the United States recently to inspect the working of the Moebius electrolytic parting process at the

Digitized by Google

works of the Pennsylvania Lead Company, at Mansfield, near Pittsburg, Pa., and the St. Louis Smelting and Refining Company, at St. Louis, Mo. His report was so strongly in favour of the introduction of this process in Germany that it was decided to instal it at the works of the *Deutscher Gold und Silver Scheide Anstalt*, in place of the sulphuric acid process heretofore used there. The plant contracted for will have a capacity of treating 30,000oz. of Doré bullion per day.

A Mountain Electric Railway.—An interesting little electric rack-railway, on the Abt system, will shortly be opened in the Haute Savoie. The line starts from Etrembières, on the Bellegarde and Annecy Railway, and runs in a circular sweep through Monnetier to Veyrier, a branch being run up the Grande Salève (2,300ft.). The gradients range from 16 per cent. to 35 per cent.; with curves ranging from 165ft. to 115ft. radius. The line comprises two short tunnels and a number of small iron bridges. Power is obtained from the Arve, which can supply a minimum of 36 cubic feet per second at a head of 10ft., say, 600 H.P. The generating plant comprises three 165 unit (275 amperes × 600 volts) Thury dynamos, coupled to turbines with vertical axes. The rolling stock consists of 12 40-passenger cars, each weighing 12 tons. The motors are four-pole, each car being provided with two 33 H.P. motors and two sets of gearing. Each car has eight brakes, viz, four friction, two electric, and two absolute. The electric brakes are formed by the motors themselves when the car runs downhill. Along the track inverted Vignole rails, supported on iron posts and brackets, form the electric conductor. A 15 per cent. loss on the line is allowed for.

Sheffield Telephone Exchange and Electric Light Company.—Negotiations have been commenced for the acquisition of the telephone business of the Sheffield Telephone Exchange and Electric Light Company by the National Telephone Company. The local company was established in 1879, and the National Company has for some years been anxious to acquire a monopoly of the telephone business in Sheffield. The competition on the part of the National Company has been extremely keen, that Company going so far as to accept subscribers at £5 per annum in any part of Sheffield. Notwithstanding this the local company has successfully held its ground and maintained its rates, which are considerably higher than those of the National Company in Sheffield, but lower than those of the National Company in other towns. Wiser counsels appear to have at length prevailed, and the National Company has now made such fair proposals to the local company that may honourably be accepted. Should these proposals be finally approved, the local company will turn its attention to the fuller development of its electric lighting business, which for some years has been steadily increasing, and more especially in view of the fact that Parliamentary powers for the lighting of Sheffield will be granted to the Company during the present Session of Parliament.

Magnetic Disturbances.—It appears that the magnetic disturbances of February 13th and 14th affected the instruments at the Pawlowsk Observatory at the same time as elsewhere in Europe, but in the reverse manner, the declination and horizontal component being markedly and suddenly diminished, while the vertical component was slightly increased. In a note in the *Comptes Rendus* of March 7th, M. Moureaux, of the Parc Saint Maur Observatory, states that an aurora borealis accompanied by magnetic disturbances occurred on the night of March 6th and 7th. The curves for March 5th were extremely regular, but during the early part of the 6th deviations from the normal were observed. At 5 p.m. the intensity of the disturbance increased. At 9:10 p.m. all the magnetic elements underwent a sudden change. About half-past six a faint aurora was observed. At 9:10 p.m. "a luminous dark red ray of light suddenly appeared at the magnetic North, developed into a fan very rapidly, and crossed the sky from North to South, passing the zenith; the phenomenon only lasted a few minutes." The great sun spot observed at the time of the disturbance of February 13th, says M. Moureaux, disappeared on February 20th, and after half a revolution of the sun again showed itself on March 4th in a much reduced condition. On March 5th, 6th, and 7th, a number of small spots were noticed around the main one, in the midst of a vast region of faculæ.

Crystal Palace Electrical Exhibition.—The following juries were appointed for the different Sections, at a meeting held on Saturday last:—(1) Apparatus to illustrate the Phenomena and Laws of Electricity and Magnetism; Electric Telegraphs and Electric Signals; the Telephone and its Appliances:—Sir H. Mance, W. H. Preece, C. E. Spagnoletti. (2) Apparatus for Electrical Measurements; Electric Batteries (Primary and Secondary):—Shelford Bidwell, Dr. J. H. Gladstone, Charles Hall. (3) Machines and Appliances for Producing Electrical Currents by Mechanical Power; Dynamical Electricity (Electric Motors):—Prof. S. P. Thompson, W. B. Esson, Ll. B. Atkinson. (4) Commercial Transmission and Regulation of the Electric Current; Application of Electric Motors:—J. H. Greathead, A. Reckenzaun, Conrad Cooke. (5) Lighting by Electricity; Heating by Electricity; Electric Welding, Stamping, Tempering, Brazing, &c.:—General Festing, W. H. Massey, Charles Hall. (6) Electro Metallurgy and Electro-Chemistry, Electricity in Surgery and Therapeutics:—J. Swinburne, Captain Sankey, J. W. Wilson. (7) Applications of Electricity in various ways not before specified. History and Statistics of Electrical Invention; Progress and Development in Electrical Science and Construction:—Prof. J. Perry. (8) Prime Motors:—Prof. H. Robinson, Sir Douglas Galton, Prof. Unwin, J. Tomlinson, W. H. Massey. Mr. A. P. Trotter was originally nominated for Section 3. He accepted on the condition that no attempt should be made to award medals for the exhibits in that class. He was willing to assist in drawing up a report. It appeared at the meeting that the whole body of jurors agreed in the uselessness of awarding medals, but that the Crystal Palace Company were pledged to give them. Mr. Trotter declined to withdraw his condition, and made a strong protest against the principle of awarding medals for such exhibits. Mr. Ll. B. Atkinson was nominated in the place thus rendered vacant. In addition to the above the following names are contained in a list sent us by the Crystal Palace Company:—Profs. W. Grylls Adams, W. E. Ayrton, George Forbes, D. E. Hughes, and Major-General Webber.

Accumulator Traction in Paris.—At a meeting of the Société Internationale des Électriciens, on March 2nd, M. Frank Géraldy gave some particulars with regard to the accumulator cars running on the Madeleine Saint-Denis (5¼ miles), and Rue Taitbout Saint-Denis (5½ miles), lines of the Société des Tramways du Nord. The loaded cars weigh 12 tons, each being fitted with two 13 H.P. 200-volt Manchester motors, running at 1,200 revolutions. Double reduction gear is employed. Each pair of wheels is mounted on a square frame, connected to the car by a pole-bolt, and supporting the body of the car on four rollers placed at the four corners. An arrangement of springs enables the frame to adapt itself to the sharpest curves. The accumulators are supplied by the Société pour le Travail Electrique des Métaux. Each car has a battery of 108 cells, each cell containing 37½lbs. of active material with 12 plates 8 inches square and ¼ inch thick. The containing vessels are of ebonite, with india-rubber lids. The batteries weigh two tons, and can supply 50 H.P. hours, which is sufficient for a run of over 40 miles. By means of three levers the driver can reverse the motors, place them in series or in parallel, or cut one out of circuit altogether, a hand-wheel enabling him to alter the grouping of the cells. Interlocking devices preclude wrong manipulations. The following table of data is of interest:—

—	Out.			Home.

GRATE AREA.*

This depends upon the amount of fuel to be burnt per hour, and is inversely as the rate of combustion per square foot, or if

G = grate area,

C = lbs. fuel to be burnt per hour,

r = rate of combustion in lbs. of fuel per sq. ft. of grate per hour, $G = C/r$,

r, with chimney draught, varies from 5lb. to 30lb. of coal,

r, with forced draught, may be from 30lb. to 120lb. of coal.

Unless the exact conditions of working the boiler be known it is well to make the grate area ample, and to reduce it by placing fire bricks on the bars, to suit the working conditions. The best results depend greatly upon the proper rate of combustion for the available draught and kind of fuel. Mr. L. E. Fletcher, in his report to the Manchester Steam Users' Association on the Wigan coal trials in 1868, says that:—

"At the commencement of the trials only 8·01lb. water were evaporated per lb. of coal, and 35·88 cubic feet of water per hour with a consumption of 20lb. of coal per hour per sq. ft. of grate; subsequently, however, the results were considerably improved, and 11·11lb. of water were evaporated by one of coal, with a speed of 46·19 cubic feet of water per hour, and 25lb. of coal per hour per sq. ft. of grate. This improvement was obtained simply by slight modifications in the proportions of the furnaces and treatment of the fires, 115 preliminary experiments were made, during which it was found of advantage to *reduce the length of the fire grate* from 4ft. to 3ft., to *adopt a blind dead plate* instead of a perforated one, and to slightly *lower the level of the fire grate* so as to increase the height of the flame chamber. No bar was found to give a better result than a wrought-iron one an inch thick, with a half-inch space as windage. The perforations for the admission of air through the fire door were also reduced from 3·2 sq. in. per sq. ft. of grate to 1·6 sq. in., while with the thickest fires the doors were left 1in. or 1½in. ajar for a minute or so after firing to prevent the formation of smoke. Both *spreading* and *coking* fires were tried, the latter giving more economical results and producing less smoke, while in addition a higher result was obtained by thickening the fire from 6in. to 9in, and again from 9in. to 12in."

Of course, it is not best to use a thick fire in all cases, though the thicker the fire the less probability there is of cold air getting through the fire. With forced draught the fire may be 18in. to 36in. thick, the length of the grate should not exceed 7ft., in fact, 6ft. is almost as long as it is desirable, and if the grate exceed 5ft. a good fireman is necessary. The breadth may be from 15in. to 4ft., the most convenient breadth being about 18in. to 30in. Long grates should slope down from the fire door about 1 in 6.

For bituminous coal a low crown, as in the flues of a Lancashire boiler, is most suitable; while for anthracite or coke, a more open fire, as in the Babcock and Wilcox boiler, is best. To obviate smoke it is sometimes advantageous to admit air at the bridge or directly over the fire, or it may be blown in by steam jets. Water in the ashpit assists in preventing the formation of clinkers.

Rankine gives the following rate of combustion in lbs. per hour, per sq. ft. of grate:—

I.—*With Chimney Draught.*	lbs. per sq. ft. per hour.
1. The slowest rate of combustion in Cornish boilers	4
2. Ordinary rate of these boilers	10
3. Ordinary rates in factory boilers	12 to 16
4. Ordinary rates in marine boilers	16 „ 24
5. Quickest rates of complete combustion of dry coal, the supply of air coming through the grate only	20 „ 23
6. Quickest rate of complete combustion of caking coal, with air-holes above the fuel to the extent of ⅓ area of grate	24 „ 27
II.—*With Draught. (Blast Pipe or Fan.)*	
7. Locomotives	40 „ 120

Formula for finding the Amount of Water which would be evaporated under Different Conditions for the same Amount of Fuel.

Let w = weight of water per lb. fuel to be found.

t = temp. Fahr. of feed water decided upon.

H = total heat of steam at pressure decided upon.

w_1, t_1, H_1 = respective values for the above as given at the trial.

then
$$w = w_1 \frac{H_1 + 32 - t_1}{H + 32 - t},$$

and if w_{212} = the weight of water evaporated per lb. from and at 212° F.,
$$w_{212} = w_1 + \frac{H_1 + 32 - t_1}{966}.$$

The following remarks have reference to the results of some evaporative tests of Lancaster and Galloway boilers carried out at Wigan, by Mr. L. E. Fletcher:—

Averages without Economiser.

	Lbs. water from 100° per hour	Lbs. water per sq. ft. heating surf. per hour.	Lbs. water per lb. fuel from and at 212°
Lancashire	4960	6·5	10·31
Galloway	4920	6·8	10·34
With Economiser.			
Lancashire	5650	7·4	11·56
Galloway	5380	7·5	11·82
With Draught shut off External Flues.			
Without Economiser.			
Lancashire flues	5170	11·2	8·23
Galloway flues	6000	11·6	8·50
With Economiser.			
Lancashire flues	6160	13·2	10·08
Galloway flues	5550	12·8	10·16

The Galloway boiler was 2ft. shorter and 6in. less in diameter than the Lancashire boiler. The Lancashire flues, having 8 per cent. more heating surface, evaporated more water with rather less efficiency than the Galloway flues. The rapidity or total evaporation was greater without the external flues, but the efficiency was less. The Galloway boiler used in the above tests, although less in size, had 6 per cent. more heating surface, and therefore should require somewhat less coal for getting up steam. Inserting four Galloway tubes in each of the Lancashire flues, making 30 sq. ft. additional surface, resulted in an increase of efficiency of about 3 per cent. at the same rapidity. Two kinds of coal were used, viz., best Lancashire and slack, with different thicknesses of fire and different modes of firing.

Deductions.

A 9in. fire was better than 6in., and a 12in. fire was better than a 9in. The 4ft. grate was better than the 6ft. in evaporative efficiency by about 9 per cent. When equal quantities of coal were burnt per hour the 4ft. grate evaporated 11 per cent. more water; but when the 6ft. grate burnt 19 per cent. more coal, the rapidity of evaporation of the 4ft. grate was about 15 per cent. less. With round coal coking fires gave slightly best results. With slack coal the spreading fire evaporated 25 per cent. more than the coking fire, but with 4 per cent. less efficiency.

Admitting air above the fire gave 7 per cent. higher efficiency, but about 3 per cent. less rapidity, while the admission

Average Results of Tests by Mr. E. L. Fletcher on Different Thicknesses of Fires at Wigan.

Character of trial.	Lbs. water at 100° per lb. coal.	Cubic feet water at 100° per hr.	Lbs. coal per sq. ft. grate.	Minutes of smoke per hour.		
				Very light.	Brown.	Black.
Coking firing fires 14 in. thick	10·35	47·22	27	2·4	0	0
„ „ „ 12 „	10·06	45·67	27	2·8	0	0
„ „ „ 9 „	9·65	44·00	27	1·0	0	0
Coking firing 12 in. thick, perforations in fire door open after charging	10·13	46·36	27	3·2	0·0	0·0
Coking ditto with perforations constantly closed	9·75	47·03	39	12·6	1·4	·6
Spreading ditto with perforations in fire door open after charging	9·81	51·37	32	20·8	5·3	4·2

The results show an evaporation varying from 5·5 to 6·5 lbs. water per hour per sq. ft. of heating surface.

of air at the bridge was about 2½ per cent. better than admission at the fire door; in these cases 2 sq. in. of air-way were allowed at the door and 1 sq. inch at the bridge. Above 2in. of air-way at the door the efficiency and rapidity both decreased, but at the bridge 3in. to 4in. could be used, without perceptibly altering the efficiency. Mr. Fletcher concludes from this that smoke must be prevented to obtain the highest efficiency, though in aiming at the highest rapidity smoke is made. Smoke was as well prevented in burning slack as in burning round coal; its efficiency was, however, about 1½lb. of water per pound fuel less than round.

Trials were made on 65 internal flue cylindrical boilers in various mills in firing slack without smoke, without loss of rapidity. The alternate side spreading system was adopted, the grates averaged about 6ft. long, and 19·25lb. coal per sq. ft. of grate.

Average results per boiler:—

Very light smoke, per hour	11·5 minutes.
Brown	2·3 „
Black	·3 „

The above table is compiled from tests made by Mr. L. E. Fletcher on a boiler of the marine multitubular type at Wigan in 1868. The boiler was of very cramped proportions, and by no means calculated to develop the highest results. It was 8ft. 6in. long by 8ft. 10in. high, 5ft. wide, and contained 124 tubes, 2¼in. diam., 5ft. long each, and two furnaces, each 1ft. 8⅝in. wide.

Heating surface of tubes	365 sq. ft.
„ „ flame chamber and furnaces, including ashpit	128 „
Total heating surface	493 „

A further test on the Wigan boiler was made with forced draught by means of a steam jet applied to the chimney, from another boiler at 30lb. pressure, when it was found that 41lb. coal were burnt per sq. ft. of grate, evaporating 69·13 cubic ft., that is, 8·71lb. of water per sq. ft. of heating surface per hour, with an efficiency slightly reduced to 10·18lb. water evaporated from 100deg. per lb. of coal.

THE BEHAVIOUR OF INSULATING MATERIALS UNDER THE ACTION OF HIGH POTENTIAL DIFFERENCES.

Mr. Spottiswoode, in March, 1882, Mr. De la Rue, in June of the same year, and Mr. Nikola Tesla, last month, have demonstrated, by brilliant experiments, the effect of high-pressure discharges from the largest induction coil, the largest primary battery, and from a dynamo of the highest frequency that has ever been known. On Friday last, the brothers H. B. and W. Fox Bourne demonstrated before the Old Students' Association the effects of a transformer, which yields a higher pressure than any previous one. It may be argued that there is not much difference between an induction coil and a Hedgehog transformer, and that Mr. Spottiswoode's coil will give a 42 in. spark. The practical difference consists in the current yielded; 100,000 volts have been exceeded by many experimenters, but 85,000 volts with 4½ H.P. behind them, that is with a current of $\frac{1}{50}$ ampere, has never been shown before a scientific society. Messrs. Siemens Bros. show experiments with 50,000 volts at the Crystal Palace, and the transformer they use is marked as being capable of giving a current of two amperes. The Hedgehog, which has been much more recently added to Messrs. Swinburne and Co.'s stand, will give 130,000 volts and $\frac{1}{3}$ ampere. The practical value of transformers yielding such enormous voltages is at present confined to experimental purposes; and it is well that experiments should be carried out with them before any attempt is made to apply them to useful purposes. The transformer used on Friday last was one with a ratio of 800 to 1, the insulation consisting of paper and oil, the whole being enclosed in an earthenware cylinder resembling a large drain-pipe.

One of the most important matters upon which all experiments with these voltages must be based is that of sparking distance; and while there are certain discrepancies between the results arrived at by Messrs. Bourne and those of Messrs. Siemens and De la Rue, there appears to be a general resemblance between them. The actual value of the sparking distance, on the other hand, is considered by Messrs. Bourne to be of small practical importance. Confidence in the results was given by experimental measurements made before the audience, and these agreed very well with the curves which were exhibited (Fig. 1). Needle points were used for the terminals, and the volts were measured with a large electrostatic voltmeter, consisting of two cylinders immersed in oil. On turning on the current the well-known violet glow of the brush discharge was seen, and as the resistance in the exciting circuit of the dynamo was diminished the air broke down, and an arc was formed. As in the Bernados electric welding process, the arcs bore a singular resemblance to long blowpipe flames. In order to show the feeble insulating powers of substances which are generally regarded as non-conductors, some very interesting experiments were carried out at pressures of sixty to seventy thousand volts. A sheet of good ebonite offered a passage to a discharge across its surface, while the distance between the terminals was many times greater than the ordinary sparking distance in air. Wires from the transformer were connected to the stalk and groove of a Johnson and Phillips' oil insulator, which had been dried and filled with clean resin oil. Brush discharges immediately occurred over the surface of the porcelain, and when 60,000 volts was reached a spark jumped from the wire to the stalk. A bar of slate, about 20in. long, 2in. wide, and 1in. thick, acted practically as a conductor, a good discharge pouring into it from the terminals; and as a further proof, two slate pencils were used to act as carbons of an arc lamp, the arc springing across a gap of some 2in., and burning quite freely. A sheet of asbestos behaved very much as did the slate. A very interesting experiment, showing the creeping discharge in a piece of dry wood, was exhibited. Copper wires were wrapped around the ends of a lath about 20in. long; small sparks, tracing charred furrows in the wood, appeared to crawl out in irregular paths from the wires, and here and there small arcs seemed to occur in the middle of the wood, and after a few moments the whole burst into flame. A block of salt about as large as a brick,

Digitized by Google

when slightly damped offered free passage for the current, which played over its surface in brilliant yellow flames. A sheet of celluloid $\frac{1}{8}$in. thick broke down instantly, as did a sheet of ebonite of the same thickness. In these experiments the current did not break down or perforate the substances, but they behaved exactly like conductors. An experiment which was shown by Mr. Tesla, and which is often demonstrated by Messrs. Siemens, consisting of a sheet of glass placed between two flat terminals, was repeated by Messrs. Bourne. A blazing network of violet threads of fire darted out all over the glass, three or four arcs ran round the edge to the other terminal, and finally the glass was perforated and the edges of the small hole became white hot and fused together, the glass in its molten state being a conductor. The glass therefore appears to be a

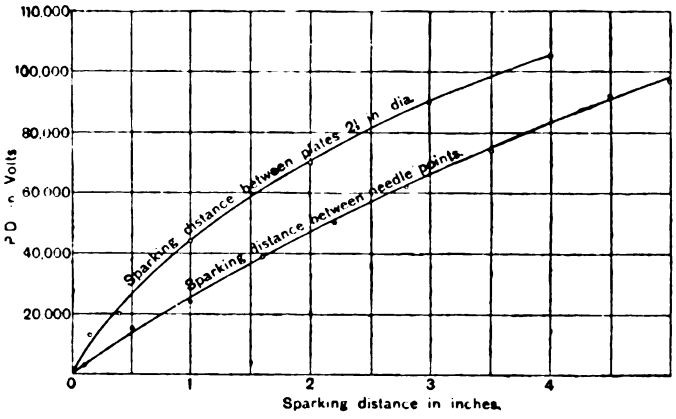

FIG. 1.

rival of oil in its self-healing properties. A specimen of good rubber-covered cable was shown. This had been wound with bare copper wire over a small portion, and subjected to 20,000 volts, acting as a concentric cable. The dielectric soon heated, owing, not to conduction but to absorption currents, and soon broke down and burned. The time element is of great importance in this case, and a very important difference exists between the effects of direct and alternating currents on insulators. Whenever, as in the case of a concentric cable, the two conductors are at all close together, we have a condenser which is being rapidly charged and discharged. Now in the case of most solid dielectrics there is a good deal of soaking in and consequent loss of energy, which manifests itself as heat. This was made very evident in the case of a condenser which was tried at Messrs. Swinburne's works. This condenser was made

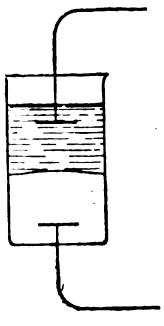

FIG. 2.

of sheets of tinfoil insulated with paper soaked in paraffin wax in the usual way; its insulation, measured with a steady pressure of 240 volts, was about 6 megohms, and the active service of plates was 5,000 square inches. When it was connected across a 2,000-volt circuit it was found to absorb more than a horse-power, so that a considerable rise of temperature was not surprising. But it was also noticed that its capacity rapidly diminished and finally disappeared, which was on investigation found to be owing to the fact that the foil had melted and so become disconnected from the circuit. Another condenser, made with glass plates $\frac{1}{10}$ inch thick, broke down with 2,000 volts after about five minutes, apparently owing to internal cracks caused by the heat evolved. In the case of the sample of rubber-covered wire above referred to, the compound in which the braiding had been soaked melted in five minutes, and the rubber became quite softened by the heat in about fifteen minutes.

The construction of transformers, condensers, and voltmeters for such high pressures would be hardly possible without oil insulation; and the authors of the Paper had a good deal to say about the use and behaviour of oil. It has been found that the heating due to absorption currents is very much less in liquids than in solids, probably because a shear strain cannot exist in a liquid. An expenditure of about $\frac{1}{4}$ watt per cubic inch of oil has been observed, and there is very little to choose between different kinds, those having a high specific inductive capacity seem to heat the most. When one electrode was placed at the bottom of a vessel containing oil, and the other, consisting of a wire, was placed just above the surface, the oil was violently repelled just below the wire, forming a depression of about $\frac{3}{4}$in. deep. A very interesting experiment with two different oils was shown. Coloured castor oil was poured into a glass beaker, and a layer of paraffin oil was floated above it. Flat-ended electrodes were connected to the transformer, and the surface of the castor oil was seen to rise or swell in a kind of hill in the middle (Fig. 2) It was suggested that this was due to the tendency for the capacity of the system to increase, the specific inductive capacity of castor oi lbeing greater than that of mineral oil. Drying by sodium, sodium amalgam, phosphoric acid, and other powerful dehydrating agents had been found to be of little benefit; but the breaking down distance in oil was greatly diminished by the presence of dust or other impurities, which placed themselves in line by electrostatic action, and formed a bridge.

Vacuum tube discharges were shown. To allow some 2 H.P. to pass, the terminals had to be large, rolls of aluminium foil were used for this purpose. The luminous effect was very small, as in Mr. Tesla's experiments, being not more, as far as one could roughly judge, than one candle or half a candle per H.-P. The frequency of the current used in these experiments was about 200 periods per second, and it thus appears that the efficiency of the light emitted by vacuum tube discharges of this frequency is extremely small. Mr. Tesla has not yet published any figures denoting the power absorbed in his glow lamps; but it must be remembered that the frequency of the currents he used was from 10,000 to 20,000 per second, so that the efficiency of his system of lighting may possibly be much higher.

STEEL-PLATE PORTRAITS

Of W. H. Preece, F.R.S.; Michael Faraday (out of print); Sir John Pender, K.C.M.G.; Sir William Thomson, F.R.S. (Past-President of the Institution of Electrical Engineers); C. H. B. Patey, C.B. (Late Secretary of Telegraphs, G.P.O.); Dr. John Hopkinson, F.R.S. (Past-President of the Institution of Electrical Engineers); Dr. Oliver J. Lodge, F.R.S., Prof. William Crookes, F.R.S. (Past-President of the Institution of Electrical Engineers); Willoughby Smith (out of print); Prof. von Helmholtz and Prof. W. E. Ayrton (President of the Institution of Electrical Engineers), have been issued as Supplements to "THE ELECTRICIAN."

A few Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, 4s. 6d, carriage paid (U.K.)

SCIENTIFIC LITIGATION.

For fourteen days in the Law Courts, besides many consultations before and during this period, some dozen of our leading men of law, science, and electrical engineering, together with as many more assistants, have been arguing, examining, replying, repeating themselves, trying to lay traps for each other, quibbling, contradicting, explaining, insinuating, and generally playing at cross purposes. No less than nine thousand seven hundred and thirty questions were put and answered, unless, indeed, they were shirked, fenced, or equivocated. In mere expenditure of time and of words there was a sad waste. That is common enough in Parliament and elsewhere; the real prodigality here was in the squandering of intellectual energy. These men, nearly every one of them keen partisans, were drawn up on two sides, and each struggled to impede and undo the work of the other. So many able men pulling together in the same direction for this space of time might have achieved some great thing. What they have succeeded in doing has been to teach and unteach, to puzzle and to weary one of the most able Judges on the bench. Side issues have been numerous; the early history of electric lighting has been unfolded, and the evils of the system of expert evidence have been displayed. On a future occasion we shall discuss the object of the dispute and the nature of the case; but at present we shall confine ourselves to the procedure of which the case of "LANE FOX v. The Kensington and Knightsbridge Electric Lighting Company, Limited" has been the latest example.

Hard things have been said about expert witnesses; and while happily no wilful attempt was made to mislead the Judge, many of the abuses of the system were sufficiently

Digitized by Google

evident. This case, tried by a non-scientific Judge, in consequence of the illness of a "brother" who is well versed in both pure and technical science, was in some respects a very striking example of one of the absurdities of our judicial system. The Judge, for we must for a moment particularize, who is well and justly celebrated for being one of the most painstaking and respected on the Bench, admitted with the utmost frankness his lack of acquaintance with electrical science. Yet this deficiency is not considered to present any serious practical difficulty. We would ask our readers to consider for one moment an ordinary commercial case tried by a senior wrangler who after a lifetime of strict specialisation in scientific matters was as little versed in financial affairs as the learned Judge is, or rather was, in electrical matters. Imagine the counsel in opening carefully explaining the meaning of a mortgage, describing the elementary principles of the formation of a public company, and sketching, with as few technicalities as possible, the difference between preference shares and debentures. Then after two or three days, imagine the Judge stopping the case to ask the difference between principal and interest, and whether a "share" meant a sum of money or a piece of stamped paper. The idea is ridiculous enough, but the parallel is by no means exaggerated. That the present method is held to be practicable is because the system of "instruction" of counsel by solicitors and of solicitors by their clients is blindly adhered to. The getting up of a scientific case devolves on one or two men on each side; and it frequently happens that their affidavits, after being carefully drawn up, are mangled by self-satisfied solicitors, and "proofs" are cut down and rearranged and so treated that the points are frittered down, and the case is hardly recognisable by the man who has prepared it; being reduced, in fact, to matter within the grasp of the counsel. Of course the clients and experts have plenty of opportunity for imparting their ideas direct to the counsel during consultations, but when has a patent case ever been tried at the termination of which one or both sides have not complained that they have been hammering this or that point at their counsel, who were quite unable to appreciate it? Allowance must, of course, be made for the fact that the mere spectator often thinks that he could have brought out a point or trapped a witness better than the counsel; but the fact remains that it is distinctly exceptional to find the essence of a scientific case fairly represented by the advocates. Cumbersome as is the system of "instruction," the ignorance of the lawyers is largely answerable both for the unsatisfactory way in which scientific cases are presented, and the tedious repetitions and waste of time which make such litigation so costly. There are only just enough scientific counsel for one case at a time; two important cases could not be carried on simultaneously. One well-known Q.C. seems to have dropped out of patent cases, while more than one young barrister of excellent scientific education and experience has never been seen in them. We hear much of the difficulty of rising at the bar, yet no juniors seem to make any effort to acquaint themselves with even the elementary science which is taught to first and second year students at a technical college. Of the hundreds of students that are turned out of these establishments, do any, finding the engineering profession over-crowded, realise that the barristers of the day who are, we will not say scientific, but capable of conducting scientific cases, may be counted on the fingers of one hand? What we have said of the Bar applies *à fortiori* to the Bench, though it must be confessed that, if the Court of Appeal and the House of Lords be included, there is a large proportion of Judges who are well able to try scientific cases.

But patent and technical cases generally differ from others in that the witnesses for the most part play a most important and peculiar part. The legal profession is fully alive to and in awe of the peculiar habits of the expert witness, whose ways are indeed proverbial. The witnesses themselves are by no means ignorant of the peculiarities of their class; but it must at once be admitted that the circumstances which are forced upon them by the existing legal procedure, combined with the weaknesses and proclivities of human nature, conduce to the results which are so frequently observed. The expert witness, in six examples out of seven, is a partisan of his side. Nothing else, of course, is to be expected when the plaintiff and the defendant appear in the box. In the *Nineteenth Century* for February, it is stated by Mr. Mead, in an article on "The Accused as a Witness," that Mr. Justice A. L. Smith has commented strongly upon the absence of the defendants as witnesses. In the case which has just closed, the learned Judge must at all events have been satisfied in this respect. He had before him the accused,—we beg pardon,—we mean the ostensible defendant, one of the principal shareholders of the defendant company, the secretary and engineer of the company, besides other subscribers to the defence. These were almost naturally keen partisans, and such witnesses are, of course, to be found in nearly every case. But we find some excuse for the partiality, even of the professors and others who appear simply as expert witnesses. No excuse is deemed necessary for solicitors or barristers, because it is by advocacy that they earn their bread,—as though experts went there for the fun of the thing! After even the first consultation it is difficult for such a witness to maintain an impartial attitude of mind. He is expected to study and to put forward the strong points of the side which retains his services, and to discover the weak points of the other; and while he cannot but recognise that his case has its weak points, and that his opponents possess some strong ones, he is naturally tempted to bolster up the former, and endeavours to shake the latter. This state of things strongly conduces to partisanship; and it needs a distinct, and often a strong effort to keep an unprejudiced attitude worthy of a man of science. As the case proceeds, how can the expert help prompting his counsel when a witness on the other side makes a mistake? or how can he refrain from suggesting questions for cross-examination? Those of the legal profession who say hard things of the expert witness seem to imagine that they could dispense with nearly all his services but those which he renders while actually in the box; and one of the many suggestions that might be made with a view of reforming the present system is the exclusion of the expert witness from consultations both before and during the case, just as is done under existing practice during the period which elapses between the beginning and end of his evidence.

It is easy to propose improved systems too radical to stand any chance of adoption; but while the present law specially provides that the Court has power to, and on the request of either party it must, call in the aid of an assessor specially qualified, and try and hear the case wholly or partially with his assistance, it is a marvel that recourse is so rarely had to this obvious privilege. It should not be difficult to choose such an assessor; for it is only necessary that he should have a fair scientific and practical knowledge of the subject, and have sufficient acquaintance with patent law, to refrain from meddling. It has been proposed that the Judge should confine himself to the points of law, while the scientific issues are decided by a jury of experts, paid by the Court for their services, but expected to be thoroughly impartial. It is held that patent actions can, as a rule, be more satisfactorily disposed of by a Judge without

Digitized by Google

a jury; for questions of law and fact are generally intimately connected, and much of the evidence relates to matters of opinion. An expert jury would, however, be able to appreciate facts which neither counsel or Judge could be expected to comprehend, such, for example, as the drop in a transformer due to resistance, while their views about matters of scientific opinion would be equally valuable. They might act as referees for witnessing experiments, and put an end to one of the most deplorable features of modern patent cases, viz., the carrying out of experiments for the purpose of backing up a particular contention, and the inevitable so-called repetition of the experiments by the other side, if the case is long enough, with absolutely contradictory results. Such a jury would resemble a Royal Commission, and its usefulness might be greatly increased by permitting the members to examine the witnesses on the technical points. After a patent case is over, experts from each side will sometimes quietly discuss for their own satisfaction, and settle in a few minutes, a matter which has been wrangled over for days. The plaintiff and the defendant, where the former is an inventor and the latter is alleged to infringe, should both appear and be examined by the jury or scientific commission in the presence of the Judge. If a single arbitrator were selected to decide on the points of law, many patent cases could thus be decided out of court at a reasonable expense.

NOTES ON SUBMARINE CABLE WORK.

BY H. D. WILKINSON.

(*Continued from page 489.*)

5. **Cable Inboard.**—While grappling, the strain is indicated on a dynamometer on board. One type of dynamometer in use is shown in Fig. 18. The grapnel rope is taken on the under side of a sheave or pulley on the apparatus, free to revolve as

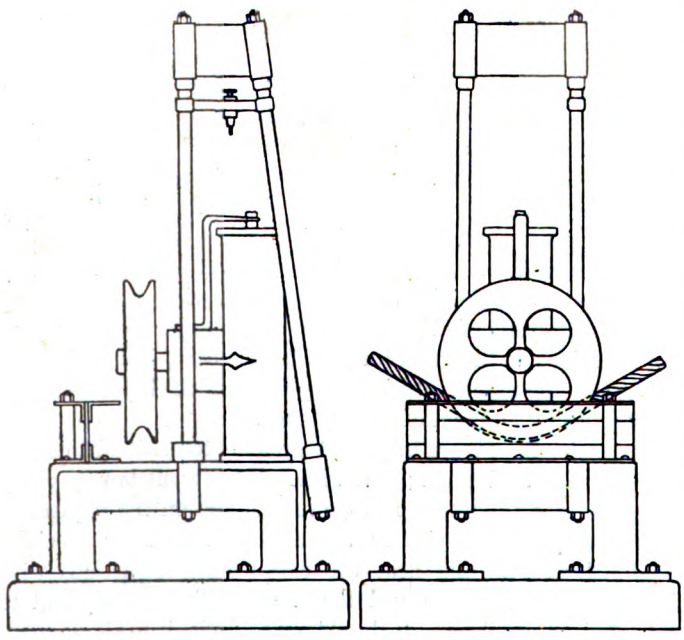

Fig. 18.—Ship Dynamometer.

the rope is paid out or picked up, and the rope is led down to the sheave at an angle and up again the other side, so that any strain on the rope tends to raise the sheave. For this purpose the axle of the sheave is mounted in a single bearing on a block capable of a vertical motion between guides, and the upward movement of the block and sheave is counteracted either by a spring or a plunger working in a cylinder filled with a mixture of water and soap or oil. In the dynamometer illustrated a cylinder and plunger brake is used, the piston rod having fixed at its top end a connecting rod coming down outside the cylinder on to the moveable block. The speed of the piston and the calibration of the apparatus is adjusted by the valve V in a pipe leading into the top and bottom of the cylinder, as shown in Fig. 18A. The resisting liquid inside the cylinder can be

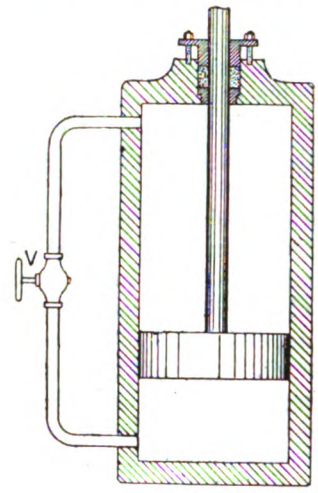

Fig. 18A.

made to brake the movement of the piston to any required amount by opening or closing the valve V at the side, and letting more or less pass through the pipe. A vertical scale is fixed on the dynamometer, calibrated in hundredweights and tons strain, but is not shown in the engraving in order not to obscure the working parts. The grapnel rope passes over one of the bow sheaves, over a loose guide pulley, under the dynamometer sheave, over another guide pulley, and then has three turns round the picking-up drum attached to a shaft driven by a steam engine. The drum is held by a powerful brake while grappling, and the ship, which is travelling only at the rate of two or three knots an hour, is stopped immediately the strain indicated on the dynamometer gives reason to believe that the cable is hooked. It happens occasionally that the cry of "Stop the ship!" is given when some jerk or strain occurs which turns out not to have been caused by the cable. Rocks, beds of coral, and deep-sea growths all impede the steady travel of the grapnel along the ocean bed, and cause heavy strains to be indicated at times.

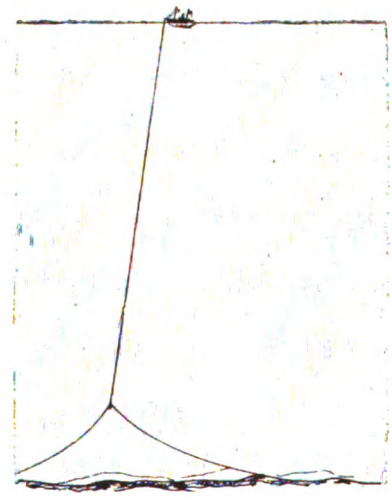

Fig. 19.—Raising Cable in 800 Fathoms.

An experienced hand will tell when the cable is hooked with an almost dead certainty by sitting on the grapnel rope near the bows. Of course it is not uncommon to heave up after some heavy strain on the rope and find that the prongs have been bent or torn off by some obstruction below. In that case new prongs are slipped on or another grapnel substituted. It is no waste of time to heave up and see that everything is

Digitized by Google

right, even though the fact that the strain is not increased as heaving up goes on makes it pretty certain that the cable is not on. If this was not done after a heavy strain the situation might be somewhat similar to that of the bottom-fishing individual who, more interested in the gallon jars surrounding his comfortable chair in the punt, doses off for an hour, rod in hand, with no worm at the other end. It is true in cable work, as in other kinds of engineering, that nothing is so certain to happen as the uncertain. Even when it is known, by the gradually increasing strain on the rope on heaving in that the cable is on the grapnel, it is always an anxious time, for the cable may be buried and the strain cause it to part at any moment. If breakage occurs the ship must steam to a fresh position three or four miles further on and commence again. When parted in this manner the length of the grapnel rope heaved in after the occurrence is measured, and a note made of the depth at which it parted; or it may part below water when in sight at the bows, or one end may be lost after the stoppers are put on.

Cables are purposely armoured with a heavy sheathing of iron or steel wires, in order to give great tensile strength to sustain several times their weight when being raised from the bottom during repair. But this very protection is subject to many deteriorating conditions, and frequently is a source of great trouble. The writer has seen cable coming in board with the sheathing in a very ragged condition, the first cause having been attributed to corrosion of the wires through oxidation in places were the preservative compound has worn off, or direct galvanic action in places that have been in contact with

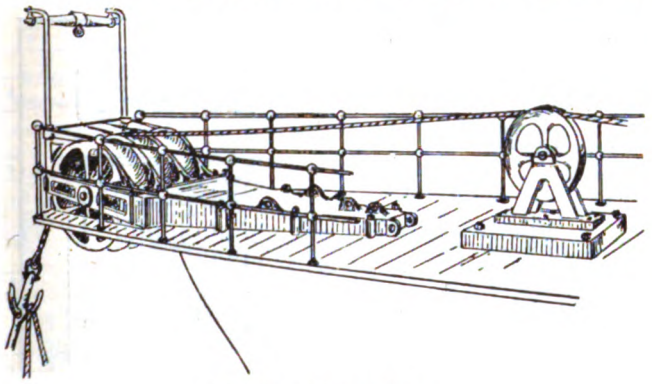

Fig. 20.—Cable at Bows.

metalliferous veins in the ocean bed. In other cases it has been ascertained to be due to abrasion against sharp projections in the ocean bed where the depth increases very suddenly, as, for instance, near the Nicobar Islands, in the Indian Ocean. The wires, so broken, leave the strain to be borne by the core, which it is seldom able to support without rupture, or damage is caused by the ends of the broken wires pressing into the core. It has been suggested from time to time to do without the iron sheathing wires altogether, and depend alone upon a hemp covering; but although there are many points in favour of this construction, there has been found some difficulty in sinking such cables during laying and grappling for them afterwards, while considerable shrinkage occurs with detriment to the core.

To afford some idea of the depth from which cables are picked up, a sketch is given in Fig. 19, showing the relative size of a cable ship 240ft. long, picking up cable in 800 fathoms. Depths, of course, vary a great deal, and repairs are more frequent in depths under 1,000 fathoms; but it is no uncommon occurrence now to raise cable from a depth of 2,000 fathoms or two and a-half times the relative depth shown in the sketch. The cable as it appears at the bows hooked on to one of the grapnel prongs is shown in Fig. 20. When fairly in view the heaving-in engine is stopped, the winding-drum braked, and a boat lowered with two or three hands to put stoppers on the cable. Two ropes are led over the bow sheaves for stoppering on to the cable, one on each side of the bight caught by the grapnel, and after these are made fast they are heaved in on one drum geared to the engine, while the other drum with the grapnel rope is thrown out of gear. The bight of the cable is then hauled on board, and the grapnel and grapnel rope being relieved from the strain are taken in. As soon as the bight appears on board at the bows a man is ready with a hack-saw and cuts it through, the ends being bared and the copper conductors connected on by binding screws to a pair of insulated wires leading from the bows to the testing-room. These are numbered one and two, and the stations on shore to which the cable ends belong is seen by the way the cable is bearing, so that it is known in the testing-room which station is on each wire. The act of cutting the cable generally produces currents or disturbs the earth or polarization currents in such a manner as to produce "kicks" or jerky signals on the mirror instruments on shore, so that some intimation of the ship having got the cable is generally to be noticed before she actually calls up.

From the moment the cable is at the bows the busiest time for the chief electrician and his assistant begins. He may be occupied but a couple of days before completing the repairs, or he may be three weeks. There is no telling till the first test is taken and picking up commences. The cable may be buried in coral and keep breaking, or the fault may be a very difficult one to localise, and be really much further off than it appears. At all events, right through the job it is continuous work day and night, with frequent testing and record-keeping of times, lengths picked up and paid out, and messages to be received and sent to keep the head office informed of the ship's movements. It may be said, as indeed it is the case, and necessarily so, that the ship's movements are under the chief electrician's orders from the moment the cable is at the bows; and the responsibility is one of no small importance.

No time has now to be lost to find out by tests on the two ends towards which direction the fault lies, and to acquaint the officer on watch which end is to be buoyed. To do this the distant ends on shore must in turn be "freed." Each end in the testing room, is then joined up in turn to the speaking-mirror connections, the station called up and asked to "free one minute" or thirty seconds; and as soon as the reply from shore comes, "O K, done," the end is instantly put over to the testing connections and the test taken. The test is simply the passing of a current direct through a marine reflecting galvanometer to the cable. If the insulation is good very little current passes; if faulty, the deflection of the instrument is large, allowing, of course, for the relative lengths of cable on each end. If the fault is very small, and polarises quickly, or the cable is known to have a length or more of low insulation cable spliced into it so as to bring down the general insulation resistance, the difference between the deflections or the insulation of the two sections may not be so great, especially if the fault is on the shorter length. It may, therefore, be necessary to repeat the tests again after this is found out; but, generally speaking, the faulty side shows itself on the first test. The other end has then to be moored and buoyed, and the ship's officer is informed at once which end is to be prepared for buoying. Meantime it is necessary to form an idea how long it will take to remove the fault, and about what time the ship will be back to the buoy again, because there is no need for the station on the buoyed end to put their men on watch again until such time as the ship returns to the buoy after removing the fault on the other end. This time is estimated by the electrician, by deciding there and then approximately how far the fault is off. If he makes it five miles off and the time is about noon on, say, Monday, he will send a message to the superintendent at this station: "Now buoy your end, keep watch after 6 a.m. Tuesday." While to the other end a message is sent: "Now buoy —— end and pick up towards ——, keep watch night and day." A message is also sent direct to the head office, giving information as to the time of arriving at position of fault, time got cable, number of miles away from shore where cable was cut, and estimated distance of fault. These messages being sent, the electrician emerges from his testing-room to find that everything has been got ready to moor the cable and buoy it; and he has only to give the word that he is ready to buoy, when the cable end is at once lowered and moored, and the buoy with the mooring chain floated.

SECONDARY BATTERIES FOR CENTRAL STATIONS.

The method of working the secondary batteries at the station of the Kensington and Knightsbridge Electric Supply Company was described and discussed in the long patent case of Lane Fox *v.* that Company with the aid of an elaborate model, provided with shifting labels, mounted on polygonal rollers. This model

was constructed under the direction of Sir F. Bramwell, from information supplied by Mr. Miller, the engineer of the Company. It does not represent accurately the particular mode employed, but shows generally the system which has been developed by Mr. Crompton. Seven different positions of the labels are shown in the accompanying diagrams, The rollers are provided with polygonal handles, bearing the letters A B C, &c. These are indicated at the side of the diagram. Several witnesses were examined on this model, which was generally placed on the Judge's desk, the witness standing by his side to move the switches, &c. The examination of Dr. Hopkinson relating to this will be found in our report of the case.

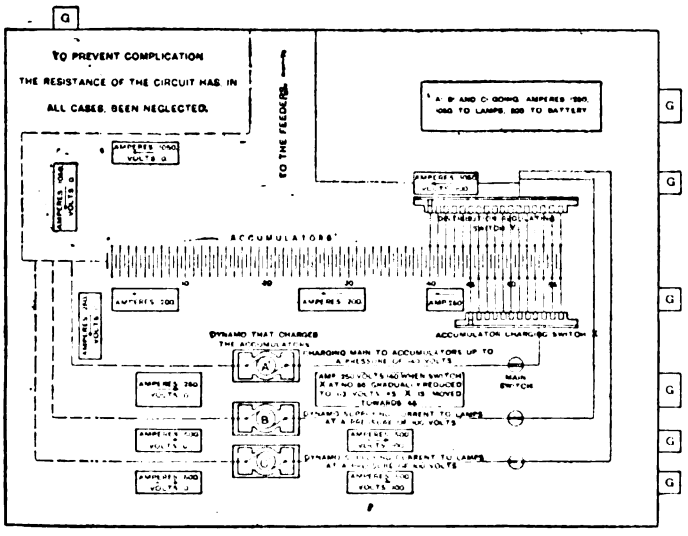
volts 140; the pressure of 140 volts being needed because, in order to charge the whole length of the battery, the charging switch X is at cell 56, and 140 volts are required (with rapid charging) to overcome the resistance of 56 cells; but as 100 volts is the assumed proper pressure for the lamp circuit, the switch Y is placed at cell 40, at which point, owing to the

Digitized by Google

resistance of the 16 cells 56 to 40, the 140 volts are reduced to the 100. The lamps at this time require 50 amperes, so that at cell 40 50 of the 250 amperes go to the lamps and the remaining 200 go to the battery. There will be seen on the tablet a statement as to how the 140 volts are gradually reduced to 113, as the high-numbered cells of the battery are charged, and the switch X is moved in succession from 56 to 55, &c., down to 45.

B.—This might have been omitted, for it is nothing more than A in its last stage, namely, when the switch X is down to cell 45. It will be understood that the 13 volts above the 100 which prevail at 45 are absorbed, as it were, in passing through the five cells 45 to 40, so that at cell 40 the needed 100 volts for the lamps still prevail.

C.—All the dynamos are now stopped and the lamps are being supplied from the battery only, the switch Y being at cell 45. The transition from B to this condition of things has been a gradual one. When the battery was about fully charged, the dynamo A′ was caused to give less and less amperes and less and less voltage, until 100 volts were reached. Shortly before the stoppage of the dynamo A′, the battery began to contribute to the supply of the lamps; on its final stoppage the whole of the current, 50 amperes (*see* the reverse direction of the arrows at the battery), is given from the battery. This condition of the supply goes on; the battery pressure falling off, involving as it falls off the gradual movement of switch Y from cell 45 up to finally cell 56. Beyond this point, the battery cannot do the work, because the pressure would fall too low.



D shows this last-mentioned condition of things and the re-starting of the dynamo A′. To begin with, the switch X is put at 56—that is to say, exactly opposite the switch Y, and the dynamo A′ is delivering the 50 amperes needed for the lamps at 100 volts only, as the current goes straight across from X to Y; but as the object is to do now that which was done in A, viz., supply the lamps and re-charge the battery, the amperes from the dynamo are gradually increased, and the pressure is gradually increased, involving the moving of the switch Y gradually from 56 towards 40, so as to preserve the pressure of 100 volts for the lamps; while the higher-numbered cells become charged the switch X is also gradually moved from cell 56 towards cell 45. It will be observed that the tablets at the battery indicate amperes 0. This is true when the dynamo is first started; but as its output of 50 amperes is increased, the whole excess of the output above 50 goes to the battery.

E.—This assumes that more lamps have been put on, and that 300 amperes are needed in the circuit. The dynamo A′ being competent to supply only 250, the balance of 50 has to come out of the battery. Both switches, X and Y, are now at cell 45; the dynamo pressure is kept down to 100 volts, as the 250 amperes from the dynamo go straight across at 45 to the lamp circuit. As the battery discharges, and the pressure would therefore fall, the switch Y is moved from 45 upwars towards 56; and as the 250 amperes are going direct from the dynamo to the lights, it follows that the switch X must at all times be on the same cell as switch Y.

F assumes that so many more lamps have been put on that 800 amperes are needed for them. It also assumes that the dynamo A′ is stopped, and that B′ and C′ are put to work, each giving 500 amperes (making 1,000 in all) at 100 volts, of which 800 amperes go direct to the lamps, the remaining 200 being dealt with as follows:—As the battery is entirely empty, it can be charged at 100 volts, not by the switch X, which was formerly used when the dynamo A′ was at work, but by putting the switch Y up to cell 56, to act under this condition as a charging switch. As the pressure in the battery rises, involving, therefore, unless an alteration were made, an increase of pressure from dynamos B′ and C′ (a condition of things which would be incompatible with the maintenance of the 100 volts in the lamp circuit), the switch Y is gradually moved from 56 to the lower numbers; and thus, although the pressure remains at 100 volts, the charging of so much of the battery as is to the left hand of switch Y can still go on. It will be seen that under this arrangement the higher numbers of cells can never become fully charged.

G assumes that the lamps now require 1,050 amperes, and that the battery has to be recharged by 200 amperes, making 1,250 in all, *i.e.*, the total product of the three dynamos A′, B′, and C′, which are therefore now all running. It will be seen that the working of the dynamo A is precisely the same as in position A, and in fact the operations during G are the same as those during A, except that the dynamos B′ and C′ being at work are sending 1,000 amperes direct to the lamp circuit to augment the 50 which it will be seen in A came from the dynamo A′.

NOTES ON AMERICAN DYNAMO PRACTICE.

BY J. D. DALLAS.

Going through the Crystal Palace Electrical Exhibition the first point that would strike an American electrical engineer is the absence, generally speaking, of self-oiling bearings. In America, except for alternators and arc-light dynamos, the best types of machines are always so fitted. The general design is a cast-iron or brass shell, resting in a spherical seat in the cast-iron standard, and provided with two partial slots in the shell, extending so far down as to allow of brass or other rings to sit on the shaft. When in motion these rings are caused to rotate by the friction on the shaft, and as they dip down below into the oil wells cause a continuous and steady supply of oil to the bearing. The spherical seat and shell are usually babbited. The one great objection which is always raised to this class of bearing is that the oil is liable to become rapidly "gummy." This, however, is not the experience of American engineers. The advantages of this type of bearing can best be appreciated by those who have had experience of both.

Compound dynamos in the United States are, of course, only used for isolated as distinct from central-station work for incandescent lighting, but generators so wound are likewise universally used for railway and tramway power stations. The shunt field circuits have nearly, without exception, rheostats inserted for a purpose to which reference will hereafter be made. The series coil is shunted very generally either by an adjustable German silver strip, or use is made of a so-called shunt board, wound with coils of insulated copper wire. The latter method is employed by one large company, six stops or contact points being provided, allowing of the grouping of the coils in nine different combinations. By cutting out more or less points less or more current is shunted from the series coils, thus increasing or decreasing respectively the ampere turns on the series field. The machines are, of course, designed to be operated with the full shunt board in circuit. But to suit the various uses to which the machine may be put after leaving the factory these stops are provided, so that a dynamo may be either compound or over-compound, as desired, the dynamo being readily and rapidly adjusted to the particular requirements of the situation. In

Digitized by Google

different parts of the country different falls of potential are allowed in the mains and lead wires. Thus a machine might be installed in a building with a 5 per cent. loss at full load, 2½ per cent. on the mains, and 2½ per cent. on the leads.

To instal a machine exactly compounded in any such building would be useless, as one of the three following devices would have to be resorted to:—(1) To bring the potential difference of the machine up to 115·5 volts (if the lamps were of 110 volts), so that at full load the lamps might be burning up to full candle-power; this would, of course, break lamps in very short order. (2) The machine might be left at 110 volts for all loads, which at full load would bring the furthest lamps down to a potential of 104·7 volts; or (3) the potential might be adjusted to 113 volts. In each of these three cases the regulation would be wretched. With an adjustable shunt the dynamo can be put to the position where the machine is either 1, 2, 3, 5, &c., per cent. over compound, and with whatever drop the wiring has been designed the lamps will be at all loads within one volt of their proper potential—that is to say, if the mains are properly designed. It is not contended that 5 per cent. is either a right or a proper loss to allow, nor is it contended that it is usual; but such cases frequently occur. The loss on the mains is determined by the contractors and local inspectors of the Board of Fire Underwriters. It may be contended that such a shunt to the series coil is wasteful; on the contrary, the percentage of watts lost is but a very small percentage of the total loss in the machine. The reason the shunt coil circuit has a rheostat inserted is that the potential of lamps which may be nominally 110 volts may vary from 105 volts up to 112 volts or 114 volts; and as it would not be convenient to make a different machine for each small difference of potential one standard is generally used, the shunt field being adjusted to the exact potential when the machine is installed, the rheostat being fixed in this position.

The Edison General Electric Company always compound their machines at 125 volts. By varying the shunt field the potential may be reduced to any point from about 105 volts up to the normal, and still be compounded, the over-compounding being adjusted by means of the shunt on the series coil. If an English firm were to think of competing for some of the enormous business in the United States, they would have in some way to modify their practice so as to conform to the general American usage. Generators, which in England would be first-class machines, might possibly be failures in America for one or other of the above reasons. Truly, the potential of a machine may be varied by altering the speed; but this expedient is seldom or never resorted to.

The writer, during several years' residence in the United States, can only recall two instances, both in New York, in which English-manufactured dynamos were met with. In one case several machines of the Siemens type were used for telegraphic work in the Western Union Building. In the other case it was a small dynamo of the Elwell-Parker type.

At least one great company in America constructs all the spiders and heads in the case of ring armatures, and the heads in the case of drum armatures, of brass or composition. As precise figures of the gain at different loads are not at hand, it may be briefly stated here that the advantages are very appreciable, resulting in increased output due to smaller core losses with the same rise in temperature. To obtain such advantages, of course, the design must be very carefully carried out. The commercial efficiencies of different sizes of machines have in every case been raised. An American engineer does not look in the first place to a machine with a very high electrical efficiency, but rather to one of a high commercial efficiency, as the C^2R losses in a machine constitute but a fraction of the total losses.

Generators for alternating currents made by one company are now all compounded, the machines themselves being either self or separately excited, the total current when commuted being used for the purposes of compounding. Such machines give very excellent regulation. The present tendency seems to be using ironclad armatures, and still more recently to alternators with armatures having no wires revolving, both the field and armature coils being stationary.

Speaking again of direct-current generators, a point which at once would call for remark, is the fact that in so few cases is any lead given to the connecting wires to the commutator of two-pole machines. The chief objection is that it is difficult at first sight to see whether the lower brush is set evenly. Absence of sparking does not necessarily prove that the setting is correct.

THE CHICAGO EXHIBITION.

The following is a report of a meeting promoted by the London Chamber of Commerce, which was held on Friday afternoon, March 11th, at the Mansion House, by kind permission of the Lord Mayor, to consider the British representation at the Chicago Exhibition.

The Lord Mayor, in opening the proceedings, said he had been asked to take the chair at this meeting, the object of which was, he thought, of the utmost national importance, viz., to see what could be done to further in any way the movement for securing that Great Britain should be properly represented at the forthcoming Chicago Exhibition. Having regard to the keen competition of the Americans, Germans, and other countries, it certainly behoved this country to be thoroughly well represented. All European countries were giving their Commissions substantial grants. There was scarcely a movement of any importance which had not deficiencies connected with it; and the great deficiency, in this instance, was the McKinley tariff. That certainly did not ease the way; but it, of course, only applied to America itself; and, inasmuch as the visitors would come from all parts of the globe, it was worth consideration, by the manufacturers of this country, whether it would not be well worth their while to send forward their exhibits, with a view to retaining and enlarging the number of their customers all over the globe.

Sir Henry Trueman Wood said a sufficient number of the representative firms had sent in their names to the Royal Commission, to make it quite certain that this country would be not inadequately represented, and further that, considering not only the exhibits from the mother country, but those coming from the various colonies and India, the British Empire would be as well represented as it had ever been at any previous Exhibition. The McKinley tariff was, after all, not such a very large increase on the Customs duties which had been maintained in America for many years. Then the tariff only affected half of the imports into the States, and with regard to one-half of the remainder, or one-fourth of the whole, it could have practically but small effect, because the goods therein comprised could not be made in the United States at all. It was by no means certain either that this tariff would be permanent. The statistics, so far as they were available, showed a falling off in British exports during the past year, but it was almost as marked in the exports to other countries as to America. This went to show that a very small proportion of this loss was due to that tariff. With regard to the distance, no doubt it involved a journey of 3,000 miles by water, and 1,000 miles by land, but this was minimised by the fact that the Royal Commission had obtained special and considerably diminished rates of freight, both by land and sea, and the American railways would also make a considerable reduction in their charges. No doubt the work of the Royal Commission would have been easier if they had had larger funds at their disposal. They could only say that they had this amount to administer, and would do so to the best of their ability; but the meeting should understand that it was an absolute necessity that additional charges should be made on the exhibits if the country were to be adequately represented. All experience showed that £25,000, however economically expended, was not sufficient to defray the legitimate expenses of a section at a foreign Exhibition. Additional funds must come from somewhere, and there was no other source except the exhibitors—those who made special profits by exhibiting. The Americans themselves looked on this Exhibition as a magnificent opportunity for robbing us of our South American trade; and they were doing their best, quite legitimately from their point of view, to take it away from us, and we must do our best to prevent them. Other countries were doing the same. It was our bounden duty to struggle to the utmost not to lose such a magnificent opportunity for advertising English industries in the presence of the great American world, and that vast crowd of exhibitors from all parts of the world who would be certain to congregate next year at Chicago.

Sir Philip Cunliffe-Owen said he ought to apologise for speaking at all, for he was an Exhibition man of the past, and they were considering an Exhibition of the future. Still there was some of the old spirit left in him yet. He did not like the idea of England being beaten by the Americans or anyone else. He was quite sure we had only to show what we could do, and we should carry the world with us. He hoped people would not be frightened at the McKinley tariff, which was held up as a bugbear. He believed that before the Exhibition was half over the tariff would be torn to pieces, because the American people would insist on

Digitized by Google

having their goods at proper prices. They learned some of the real price of goods on their visit to this country; but when they saw the prices marked on the goods in the Exhibition, they would insist on having the goods at the proper prices from the old country which had served them so well. He took it this was the final effort, and we were bound to show our relatives in America that we were still alive, and were not going to be superseded by the Germans.

Mr. M'CORMICK (European representative of the Chicago Exhibition Executive Committee) said reference had been made to the effect of the M'Kinley tariff on the trade with America; most present knew probably, though they might have forgotten it, that the Americans were, far away, England's best customers; for in the first nine months of last year, during the operations of the M'Kinley tariff, there were over £21,000,000 sterling in manufactured articles sent to America; whilst Germany, the next best customer, took about £14,000,000. That was a trade which England could well afford to cultivate. He might also say that what America knew about tariffs she had learnt from England. It was only a few years ago that England abolished the tariff, and that was when she felt herself strong enough to throw down her gauntlet to the world. America had never gone so far as England had in protecting her woollen trade. She had never placed an embargo on the export of cotton, which might have been done if there was anything hostile in the passage of a Tariff Act; but had allowed England to take American cotton, manufacture it, and send it back again, paying the freight on it both ways to English carriers. He hoped that when he returned to Chicago, at the opening of the Exhibition, he should be able to feel proud, not only of the exhibits of his own country, but equally proud of those furnished by Great Britain, and to congratulate his friends of the Royal Commission on the good work he was sure they would accomplish.

Sir DOUGLAS GALTON said he believed they would have an opportunity there, which was not allowed at Philadelphia, of stating on the exhibits what the price would be apart from the duty. If this were allowed, it could hardly fail to strike a serious blow at the McKinley tariff.

Sir OWEN BURNE hoped all present would take to heart what had been said, and that there would be a good British exhibit. He wanted all to put their shoulders to the wheel, and bring out Old England in the position she ought to occupy, especially as this might be our last struggle to maintain our place in the commerce of the world.

Sir A. K. ROLLIT, M.P., said there was a great deal of justifiable feeling about the McKinley tariff, but there was hope it would not be permanent. Already some concessions had been made which should be appreciated. He had reason to believe that the real true price at which articles could be obtained in England, irrespective of duty, would be allowed to be marked upon them, which would be certainly a benefit to the exhibitors of this country. It would prevent any misapprehension, and might illustrate certain economical principles for the benefit of America. The official date for applications to exhibit had passed, but there was still some space left, although it was rapidly being occupied, so that early application was necessary.

A vote of thanks to the Lord Mayor having been carried by acclamation, the proceedings terminated.

SOME EXPERIMENTAL INVESTIGATIONS OF ALTERNATE CURRENTS.

The following is the authorised abstract of the concluding portion of the discussion on Mr. Alexander Siemens' Paper at the Institution of Electrical Engineers, which took place on Thursday, 10th inst.:—

Mr. HOUSMAN referred to some curves in Mr. Siemens' Paper showing that the loss by hysteresis increased with the number of $\sim$ per second. These curves were, he pointed out, the loss by hysteresis *per second* and not per cycle; if the latter value were plotted it would be found that the loss per cycle decreased very materially with increase of $\sim$. This he confirmed by experiments of his own with low frequencies varying from 3 to 30 $\sim$ per second.

Mr. RUSSELL had tried many experiments to see if a spark micrometer could be relied on as a rough voltmeter for an induction coil spark, and had come to the conclusion that it was quite unreliable, the results varying 5 to 10 per cent., even when the greatest care was taken to polish the electrodes. He also showed some curves of sparking distances between balls, spears, and points. Unlike Mr. Siemens he had found a very great difference with differently shaped electrodes; the sparking distance being at 2,000 volts three times as great between two spears as between a spear and a ball, and the ratio increased as the volts were raised. In no case did he get so short a distance as Mr. Siemens. He had found that time had a very distinct effect on sparking distance. An E.M.F. which would not cause a spark at once would often do so if left on for one or two minutes. He objected to the expression of sparking distance in volts per millimetre. All the curves of sparking distance with various volts were convex (to the axis along which E.M.F. was taken), *i.e.*, the volts per millimetre decreased as the volts themselves rose; in some of the curves to as much as 25 per cent.

Mr. ESSON suggested that it would be well in the cable transformer to bring the two ends together and get a closed iron circuit. He also showed some curves giving the all-day efficiency of two transformers, the one with the copper loss three times that in the iron, and the other with the iron loss three times that in the copper. The all-day efficiency of the latter appeared to be nearly twice as great as that in the former, both curves were based on the average load curve of the Kensington Court Station.

Mr. SIEMENS, in reply, said that Prof. Perry had thrown some doubt on the temperature determinations because they depended on the measurement of ·002 ohm in ·7 ohm. He could assure him that there was no difficulty in making such a measurement to that degree of accuracy, and that it was done every day in practice. Mr. Evershed had also doubted the accuracy of the method; but he, the speaker, would point out that it was a very well known and tested one, being in fact nothing but that of the electrical thermometer of the late Sir W. Siemens. In reply to Mr. Russell, he could only say that he found that when the electrodes were carefully polished, *his* results *did* agree within one per cent., and that he had found that time had no influence whatever on sparking distance. He did not think that closing the iron circuit in the cable transformer would be of any appreciable advantage, the induction was a little less just at the ends than elsewhere, but not enough to trouble about.

LEGAL INTELLIGENCE.

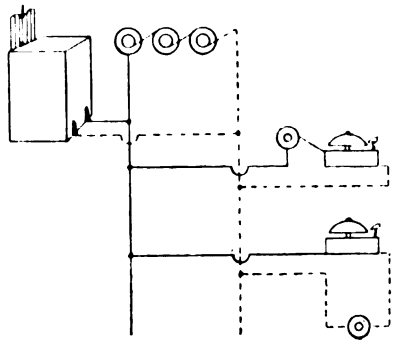
Lane Fox v. Kensington and Knightsbridge Electric Lighting Company (Limited).

FRIDAY, MARCH 4TH.

Mr. FINLAY, examining Sir FREDERICK BRAMWELL, said: If it were practicable, would there have been advantages in returns by "the earth"?—Yes; economy of material.

Mr. JUSTICE SMITH: Is that a very large expense?—It would be one-half the total expense of a system where there are two metallic conductors. You would save one-half if you ask me what is the expense of conductors. I believe I am right in saying that in this Company, the defendant Company, out of a total expenditure of about £135,000 to £140,000, some £35,000 to £40,000 represents the cost of the conductors out and home. In round numbers, therefore, it is a little under a third of the total expenditure. Then I ought to say that of that a certain portion is the conduit and a certain portion is the copper. The economy would be that you would do with one-half of the copper. I do not believe a return by soil to be practicable for electric lighting, having regard to the large number of amperes that have to be dealt with. Telegraphy, I think I am right in saying, may be measured by a very small fraction of an ampere; and in my own house, if I had all the lamps on at once, I should have about thirty-eight amperes passing through it.

Questioned on Clark's Specification, the WITNESS said: Clark's Specification has no drawing to it. Reading Clark's Specification I have drawn



this (F.J.B.1.). There is a primary battery of three cells. It is to be one of a constant current, that is to say, not one of the old batteries that used to go out of work in a few minutes, and that is to be coupled up at the same time to a Planté battery. The Planté battery is to make a wire so hot as will ignite a taper or a match—the primary battery is to charge the Planté battery and to ring bells. The two may be left in connection, and both batteries will serve to ring the bells. If a workman of intelligence acquainted with the subject were reading the Specification, he could carry out the plaintiff's directions, but I do not think the result would be successful.

Mr. FINLAY: The suggestion was made that that difficulty might be got over by increasing the size of the plates used in the secondary batteries.—I say it is commercially impossible because of the excessive cost, if for no other reason.

The ATTORNEY-GENERAL: I respectfully object to this. It has been ruled, as your Lordship is aware, that commercial cost is not the test of utility.

Mr. JUSTICE SMITH: Well, I cannot shut it out. Suppose it cost £100,000 and only brought in a guinea a year, I could not shut that out.

Digitized by Google

The WITNESS: The cost of our batteries and their adjuncts was on the 31st December last £13,600, which again, in round figures, is 10 per cent. of our total capital. I as a shareholder should be very sorry to see that £13,000 increased to £65,000, which is five times as much. It would be loading the concern with an absolutely useless amount of capital. Whatever we think good enough for the outgoing conductor in the way of insulation that very same thing is applied to the return. The defendants have a system of feeders or feeding mains. Witness produced a map (issued as a Supplement with *The Electrician*, January 15th, 1892). The feeding mains are not shown, but the places where the feeding mains join on to the circuit mains are indicated by red dots. The feeding mains have no lamps upon them at all. The current reaches the point of delivery at the requisite voltage, the loss by resistance being taken up before there are any lamps to be supplied.

These feeding mains are adjusted in point of resistance to the length the electricity has to travel, so that, although the resistance varies as the length of the main, other things being equal, you get a uniform pressure in the generating station and a uniform delivery in the lamp circuit. That is to say, if it has further to go the sectional area will be larger, so that there is less resistance. There is a third kind of main, we have between the Kensington and the Queen's Gate Battery Station a pair of charging mains—I discriminate between lamp-circuit mains, feeder mains, and charging mains—there are no lamps upon those, of course. The Witness then went on to the bench and explained by the use of a model, the different methods of connection, the Attorney General standing by. The Witness then stated that the secondary batteries were employed by the defendants for the purpose of economising labour, and for the purpose of enabling them to work their steam engines with more efficiency. Having these batteries they could always give a load to an engine when working it. If the circuit did not want it the battery did.

Cross-examined by the ATTORNEY-GENERAL, Sir FREDERICK BRAMWELL was questioned at some length on the early use of secondary batteries, on Prof. Ayrton's curves, and on the system of feeders used at Kensington.

The ATTORNEY-GENERAL connected the two "earths" on fig. 5 of the Specification* by a pencil line, to represent an uninsulated conductor, and asked whether, supposing the secondary battery were put between the "n" and the earth, the position, from an electrical point of view, would not be exactly the same?—No; I should certainly say not, because then you would have the battery and the generator in series.

I will take it that you thought that the meaning of putting the secondary battery between the negative pole and the earth would be to make it in series?—I should have thought so.

Very well; I will take your answer. Now I wish to see if I can appreciate this distinction that you have taken. As I understand, the sole distinction that you draw between the position of the secondary battery in Lane Fox's patent and at Kensington is that you have it between the generator and the lamps?—No, that is not so. That is not my sole distinction, or anything bordering upon it. I hardly know how to separate position from connection.

Mr. JUSTICE SMITH: You say it would make no difference whether the battery was put immediately after the energy went out of the dynamos, or whether it was put at the other end of the line?—I think none, my lord, except upon the question of uniformity of distribution.

The ATTORNEY-GENERAL: is not the real object of putting it in between the generator and the lamps in order that you may get the opportunity of cutting in and cutting out cells for charging and discharging?—Yes, I should say that is the object.

The ATTORNEY-GENERAL set the model to show the dynamo developing 300 amperes, the two battery switches being at 50, and assumed that the dynamo gave 103 or 104 volts, and asked whether the arrangement was not that of Lane Fox pure and simple, and whether the batteries would not become charged until the potential rose to 103?—The WITNESS admitted, with certain qualifications, that this would be the case. He believed that one feeder would stand for hours at the same potential without any alteration during the time there was a small draught; but denied that, whatever the interval, whether one hour, if there were many lamps on, or two or three hours if there were few, the secondary batteries would be acting as regulators, because they would get precisely the same regulation from the engines if the batteries were not there.

If the engines ran at a constant speed, was it not known that the sudden putting on of more lamps either raised or lowered the voltage of the generator?—Yes; with certain generators, and unless corrected.

Now, I will assume that with such a dynamo you coupled up between the main and the earth secondary batteries of the voltage that you desired your lamps to be, do you follow me?—Yes.

And that you ran your generator at a constant rate of speed, having your secondary batteries in between the main and the earth. Would not those secondary batteries tend largely to correct the rise and fall of voltage when lamps were turned on and off?—I think they would.

Assuming the engine to be always running constant to that extent, would not the secondary batteries act as maintaining or tending to maintain a constant E.M.F. at the lamps?—Yes.

Assuming that at Kensington Court the discharge switch remains unaltered (the switch Y) for an hour, an hour and a half, or two hours, is not that exactly the effect that the secondary batteries have upon the pressure of the lamps if the engine maintains a constant speed?—Yes; I should think so, and if we did not also alter the field magnets.

I am not asking about other methods of correcting. I am putting a dynamo such as would be used in 1878.—There was in 1878 a mode of varying the intensity of the field magnet.

That is another method of correcting it, but assuming the field magnets to remain as they were at the time of the given running and not to be altered, would not the operation then be at Kensington Court exactly what I have suggested to you, namely, to keep constant the E.M.F. at the lamps?—I think so, but you only gave me one condition, which was the engine being maintained, and I wanted to point out that we had another mode, and did use it, of regulation.

That is a method of correcting it in another way.—Other than the speed being maintained.

I say it is a method of preventing or correcting the fall or rise of voltage in another way.—Yes.

SATURDAY, MARCH 5TH.

The cross-examination of Sir FREDERICK BRAMWELL by the ATTORNEY-GENERAL being continued, the witness thought that the absence of flicker or the maintenance of steady light was not largely due to the secondary batteries with steam-driven plant. Without the battery the thing would be perfectly uniform for all practical commercial purposes.

Mr. JUSTICE SMITH: Are you driving at the fact whether or not the application of the secondary batteries has a regulating effect or not?

The ATTORNEY-GENERAL: That the user of the secondary batteries, as and when they use them, my lord, most distinctly regulates these lamps, and keeps the pressure constant, as and when they use them.

Mr. JUSTICE SMITH: Go on. I do not think there is much doubt about that.

The ATTORNEY-GENERAL: I will not complicate it; your lordship knows the difficulty.

The WITNESS: If I were allowed, I might shorten the matter by saying that, in my opinion, you cannot have batteries constantly coupled up for the purpose of storage without at the same time there being, as an incident of their use, a certain amount of regulation. Whether needful or not I am not now saying.

Further questions were asked about the use of storage batteries in connection with gas engines, and about the meaning and use of the term "earth."

Mr. JUSTICE SMITH: Apart from the special verbiage of this specification, my mind is clear that it has been proved over and over again, and nobody disputes, in 1878 an engineer might have read it as being an A, B, or C return—I want no more on that. I have calculated it up, and I think we have spent more than one day on this word, the "earth." Sir Frederick has told me his view, and that is clear.

The ATTORNEY-GENERAL: Then I will not trouble one bit more on this. If your lordship will bear with me one minute I will call your attention to this. I ask you kindly to have in your mind, or note, the citation with reference to the sheath of iron wire: "This is overcome by using a sheath of the iron cable itself as the earth." I do not want to examine upon it, I only want your lordship to have that in your mind.

Now I ask you, was not the great problem in 1878 the distribution of the electric light?—Yes, I think so.

Was a Government inquiry held in the early months of 1879 with reference to the practicability of electric lighting?—Yes.

Were Prof. Tyndall, Sir William Siemens, Dr. Hopkinson, Mr. Deacon, Mr. Keates, Sir William Thomson, Mr. Conrad Cooke, Mr. Douglas, Mr. Stephenson, Mr. Preece, Mr. Burleigh, Mr. Woodall, and Mr. Lugg, examined before that Commission?—Well, I do not remember the whole of the names, but a large number of the best known names were—Sir William Siemens, Prof. Tyndall, Mr. Keates, Mr. Preece, and Mr. Deacon.

Can you tell me, was a single one of the eminent electricians who treated or described the distribution by subdivision of the electric current as being possible or practicable at that time—I put to you the spring of 1879?—I cannot tell you with certainty, but I can tell you that I believe the general opinion was that there was at that time no well-established well-known system of separation. I believe the investigation turned chiefly on arc lighting.

Had anybody to your knowledge, prior to the beginning of 1879, published—observe the word "published"—any practical system of distribution by multiple, parallel, luminous, incandescent, bridge—a multiple incandescent bridge?—I only use the word "parallel" in the sense that they go between the main and the return. I know of one with a sort of semi-incandescent lamp, which I believe was published before 1879. I think I know of two. Incandescent bridge pure and simple I do not recollect, but an arc not an arc lamp.

Before 1878 was not the Jablochkoff candle worked in series?—To my personal knowledge it was worked in series.

The Jablochkoff candle was the nearest approach to what I call subdivision that has ever been achieved prior to, we will say, Edison and Lane Fox's discoveries?—It does not so occur to me; I do not see it is anywhere nearer subdivision than anything else.

Were you acquainted with Mr. Lane Fox's practical work before 1878?—No.

He is talked of as a young man, and a man who knew nothing?—I wish I suffered under the same complaint.

Questioned about the use of earth returns, witness had no idea whether six yards square or six feet square would be sufficient for an earth plate to carry 50 amperes; he knew that uninsulated returns were used at the Leeds tramway.

After some questions about the arrangement of tinder boxes and electric bells in Clark's patent, the ATTORNEY-GENERAL asked: Now, with reference to known means in 1878 for distributing potential, with or without the aid of secondary batteries, can you point me out, or tell me—and I must say, can you produce to me—a single reference to Clark, or a development of Clark at any time prior to 1878, or subsequent, with the object of breaking up the current at a constant potential, distributing current at a constant potential?—No.

Have you ever considered Clark with reference to this problem till you were asked to advise your own Company in this defence?—I do not think so. I do not recollect it before.

---

* *The Electrician*, Feb. 26, p. 438.

Digitized by Google

Can you point to a single book, a text book, or elementary book, or even non-elementary book, right away up to the present day, which to Clark as an analogous use ——?

Mr. JUSTICE SMITH: Do not you think we have had enough of Clark?

The cross-examination was concluded by some questions about "feeders."

Re-examined by Mr. FINLAY, Sir FREDERICK BRAMWELL said that a current of 10 amperes returning by the soil would be of no practical value, since his own house took 38 amperes. He referred to the patents of Woodward in 1875 and Weidermann in 1878, which described parallel distribution. Asked whether there must be a tendency to regulate wherever secondary batteries were coupled up with the dynamo, witness said that wherever they were used for storage purposes, as an incident to that use there must be some tendency to regulate. But the regulation was not automatic, except in so far as it was an incident of the connection at any particular moment, that was automatic; but in so far as the practical regulation was concerned it was non-automatic, and he added that with a steam-driven plant one could work perfectly without the slightest fluctuation of any sort or description, if the batteries were put out together.

With reference to his answer in cross-examination that it would make no difference to Mr. Lane Fox's patent, pure and simple, if the battery were put on (Figure 5) immediately outside the dynamo, or where it was put, WITNESS wished to add that that would not be operating upon the mains by dotting batteries about the mains. It would be putting the battery in an improper place, because it would be close to another source of power, the dynamo being a source of power, and the battery being a storage of power. He would understand the storage would not be put close to the source.

Dr. JOHN HOPKINSON (examined by Mr. R. W. WALLACE), in reply to questions, pointed out that the lamps used by the defendants employed carbon *in vacuo*; but the lamp described in the patent was of platinum and iridium in nitrogen. These lamps were well known as laboratory instruments—they were never well known as articles of commercial use—in fact, they never had any commercial use.

Mr. JUSTICE SMITH: Is this on the point that you may have taken all the other inventions of Mr. Lane Fox and not infringed his patent as to the lamp—is that the point? There are many issues I have to decide, and I do not want to decide more than is necessary. This is disclaimed.

The ATTORNEY-GENERAL: I rely distinctly on the system of distribution. I say that is absolutely new, and that that is in the claim that is left.

Mr. JUSTICE SMITH: And you say that that system of distribution involves regulating, which you claim?

The ATTORNEY-GENERAL: Certainly, and I further say this, with regard to the lamp, the only question asked was with reference to the general character of the lamp, to show it was understood by Mr. Lane Fox in the system he was describing. I never claimed or suggested the defendants have taken our improved lamp. On the contrary, I admit at once the Edison carbon lamp is very much improved beyond that of Mr. Lane Fox, and was adopted by everybody. I have not asked a question on the lamp.

Questioned as to the term "earth," the WITNESS gave the following definition:—"The soil of the earth or anything electrically connected to earth which an electrician finds ready placed to his hand and uses as his second conductor, and so saves the expense of providing a special conductor *ad hoc*." I should say that on my definition the gas and water pipes would be "earth," or "the earth," but I find in Mr. Lane Fox's specification that he does not appear to use the term in so wide a signification as I should use it. I refer to page 4, line 20.

The WITNESS then referred to Noad's book, published in 1857, page 754, article 1,064, and to "Lardner's Handbook on Natural Philosophy," fourth thousand (1861), page 264.

Mr. WALLACE: Do you find there a similar use of the word "earth" and "the earth"?—Yes, it puts in this, "But it was afterwards discovered that the earth itself was the best and by far the cheapest, and most convenient, conductor that can be used for this return system of electricity."

Would it be a desirable thing for electricians if they could have used the earth as a return?—Yes, if the earth had played the same part with the heavy currents required for electric lighting.

Mr. JUSTICE SMITH: Now this is more important. Do you or do you not say that this return under Lane Fox could be worked by earth?—Only on a very small scale, a very small scale indeed. I should not like to fix the precise limits. I should not be afraid of working 10 amperes, but I should feel very uneasy in working 100. I think I might put it in that way. I would not say it could not be done. I say you could not go to 1,000. If you had 1,000 amperes that would generate oxygen gas enough on your earth-plate, if you used an ordinary, earth-plate to oxidise about 2lb. of iron per hour. Of course, that would be a rather serious matter with water pipes, as the oxidisation would be localised in particular places, and, independently of that, you would have great difficulties with the resistance that would be introduced—in fact, insuperable difficulties.

Mr. WALLACE: Would that be at all a practical means to use on such a system as the Kensington Court system?—No; certainly not.

Mr. JUSTICE SMITH: That is not the point, is it?

Mr. WALLACE: Well, on such a system as contemplated by this patent?

Mr. JUSTICE SMITH: Yes, that is the point.

Mr. WALLACE: Would earth returns be successful?—No, I think not.

Mr. JUSTICE SMITH: Tell me, do you know any electric lighting system in which they work earth returns in this country?—I think for a time Sir William Siemens worked it at Holyhead for arc lighting—a number of arc lights in series, and I suppose they would take perhaps 10 or 15 amperes through those, probably not more; and they discontinued it, I did hear, on account of the disturbance to the telegraphs. I have not seen that installation. Holyhead is a seaport, and they may have possibly taken the earth-plates down into the water; by "earth" I should have included the sea, of course.

Mr. WALLACE: In 1878 was or was not parallel distribution for electric lighting purposes known?—I should think it was familiar to any competent person that the work could be done in that way, or as soon as you had the proper lamp. I certainly knew it.

Mr. JUSTICE SMITH: You knew what in 1878?—That you could distribute electricity by a parallel system.

Mr. WALLACE: I will read you a passage from Kosloff's specification, which was published in 1875, No. 441: "The system of placing the lamps into the circuit may be effected in two ways, either by placing one series of lamps united by a metal wire in such a way," &c., &c. [*reading down to the words*] "the conductor at the other pole being in communication with the last lamp." Now, does not that describe working in series?—Yes.

Mr. JUSTICE SMITH: Where do you find that?—I think it is at the top of page 9, my lord.

Mr. WALLACE: "Or by subdividing the current, that is to say, the current at one pole is subdivided," &c., &c. [*reading down to the words*] "each lamp."—Yes.

What system of distribution does that describe?—Beyond all doubt, parallel.

WITNESS then referred to Woodward's patent 181,613, American specification 1875. Parallel distribution was described, but no claim was made for it. Jablochkoff, 3,839 of 1887, was also put as an example of parallel distribution; Leyden jars or condensers were used.

Mr. JUSTICE SMITH: There is nothing new in 100 volts?—No, no special merit in it, my lord. I use in my house 50. In these Courts there are about 85; and I think at Paddington they use 130.

MONDAY, MARCH 7TH.

The examination of Dr. J. HOPKINSON by Mr. R. W. WALLACE being resumed, the witness described experiments made at his own house with storage batteries. He always charged his batteries to a high point, not so much for the sake of potential in discharge as for the sake of the health of the battery.

Questioned as to the plateau, he said there were, in fact, two plateaux. There was a plateau which was not very flat in charging; there was a plateau which was much flatter in discharging. Those two plateaux differed very materially in their potentials. If he did not occasionally go up to 57 or 58 volts the cells would suffer. They would not last. Actually he made a practice of always being sure that they did get up to that once a week, and he thought they generally got up about twice a week to it. If he did not he would find the plates begin to buckle and get out of shape, bend, and come in contact with each other, and once they came into contact the battery was ruined. He did not find any direction to that effect in the specification.

Questioned as to the effect on the lamps of the high voltage used for charging, the witness gave the following figures:—

Volts.	C.-p.	Life.	Volts.	C.-p.	Life.
115	—	30	92	9½	—
105	—	310	80	4	—
100	16	1,000			

He did not think they ought to allow more than 2 per cent. variation from the mean. It ought to be kept well within that. If they had 101 volts on the battery they would get a very small current passing for a short time. That current would rapidly diminish and speedily become practically *nil*.

Mr. WALLACE: Assuming the batteries were taken away altogether, in your experience as an engineer what would be the effect on the constancy of pressure in the mains at Kensington Court?—Absolutely none. They work in that way at Gatti's installation in the Strand with a large station. There are scores of that kind of station in America—Edison stations.

In your opinion are batteries in such a situation as Kensington Court of any practical use for keeping constant the electromotive force except during the time they are solely used for replacing the engine and dynamo?—Quite so. In my opinion they are useless for regulation with the exception you named. Their use is to enable you to allow your workman to go at times when the demand is small.

Cross-examined by the ATTORNEY-GENERAL, Dr. HOPKINSON said that he had not made any prolonged personal observations as to the variations of voltage in Gatti's installation.

Questioned about the Select Committee of 1879, he said that there was at that time no incandescent lamp. He regarded it then as entirely a problem of how they were to deal with the arc lamp. He admitted that he had said, speaking of the platinum iridium lamp, "It ought with proper management to last an indefinite time." But he remembered afterwards that he went into some explanation as to the greater economy of the arc, owing to the higher temperature, and so on, there was then a difficulty as to the arc; he always held there would be no difficulties as to incandescent light.

Mr. JUSTICE SMITH: You know Sir Frederick Bramwell has told me the great question of the day in 1878 was this subdivision of the light.

The ATTORNEY-GENERAL: Yes, I have enough, my lord.

The model being placed at position D, the ATTORNEY-GENERAL suggested that the current began with both switches put at 56, and as the current increased they moved the discharging switch Y gradually from 56 towards 40. Was not the sole reason of moving the switch from 56 towards 40 because the batteries getting charged there would be too much pressure in the mains?—Yes. No amperes apparently were going into the boxes.

Digitized by Google

To begin with, the switch X is put at 56, that is exactly opposite the switch Y the dynamo is delivering the amperes needed the lamps at 100 volts only, the current goes straight across, but as the object is to do what is done now, namely, to supply the lamps and recharge the batteries, the amperes in the battery are gradually increased. They begin at 100 and the pressure is gradually increased, involving the moving of the switch Y gradually from 56 towards 40 so as to preserve the pressure of 100 volts for the lamps. That is because, as the cells get charged, you get too much pressure for the lamps, and accordingly you move the discharging switch in accordance with the pressure of the total number of boxes, so as to procure the pressure of 100 volts for the lamps. Now, before it is moved from 56 to 55, the box 56 will be rising—we will put a hypothetical figure—it must be less—it must be about 1·8.—It would take less than half an hour or an hour, before it gets up to 1·8.

I assume during a quarter of an hour or half an hour the switch stands at 55.—No, less than that. Take it five minutes. Lamps are turned on and off in the circuit, and the secondary battery would not be acting during that five minutes exactly in the same way as Mr. Lane Fox describes, because during the whole time you are charging the battery. By the time you get to the 125 switch Y will be moved down to 46. To move it right away down that depends on the condition of the batteries at the beginning and the rate you are pouring electricity into them. The dynamo supplies not only the battery, but external work as well. The time occupied from switch Y getting from 56 to 40 depends on how many amperes are coming out of the battery—how much is wanted for the lamps.

Now I take the case before you move the switch at all, while the voltage is rising from what it was at starting, till it is necessary to move the switch from 56 to 55. Is not that working pure and simple as Lane Fox's during that period?—So far as Lane Fox there goes.

Yes, certainly?—Yes.

During that time WITNESS did not think that the existence of the secondary batteries in that position as being coupled up with the return wire regulated the pressure at the lamps to any sensible extent. If the steam engine was very bad and the man was very neglectful, then, no doubt, it would become more material; but with proper management it was absolutely unimportant and useless.

Would not the fact of those batteries being charged at that time in the way shown at D tend, when those lamps were suddenly turned on, to keep the electromotive force constant at the moment?—Yes, under those extreme conditions.

It is a question of extent. Would you be kind enough to turn them all to E, and then I shall not have to trouble you to go back again? "This assumes that more lamps have been put on, and that 300 amperes are needed in the circuit."—Yes.

"The dynamo A being competent to supply only 250, the balance of 50 has to come out of the battery."—Yes.

Now, I am going to point out to you presently that this is the second stage of Lane Fox.—Yes.

"Both switches X and Y are now at cell 45. The dynamo pressure is kept down to 100 volts as the 250 amperes from the dynamo goes straight across at 45 to the lamp circuit. As the battery discharges and the pressure would therefore fall, the switch Y is moved from 45 upwards towards 55, and as the 250 amperes are going direct from the dynamo to the lights, it follows that the switch X must at all times be on the same cell as switch Y." Now, I ask you whatever the number of cells be, keeping the switches X and Y opposite one another, and 50 amperes coming out of the batteries, and 250 from the engines, is not that a direct instance of the use of the second part of Lane Fox?—Yes; but he does not show how he gets from one stage to the other.

You will forgive me for not arguing the matter with you; I want to get my question answered. Now, Dr. Hopkinson, during that time if a theatre is turned on or if a fog comes on and a number of houses suddenly are turned on, would not the presence of the secondary batteries, coupled up as they are, discharging like that, tend to keep the electromotive force constant?—No, not to an appreciable extent—not in the latter case.

Would they tend to do it?—"Tend" when there is something else that governs it.

What is the other thing that governs it?—The man at the steam engine.

Then it does come to this ——?—That if the man at the steam engine fails you may get some benefit from that, if the man is away or anything of that kind.

Or if the personal error of the man with regard to quickness of observation and quickness of action is greater you get an advantage?—I cannot imagine any such excessive personal error as that.

Do not you know that into these questions of regularity personal equation does largely enter?—It does, no doubt; but then the degree of accuracy you require to get is so very much greater than what you will get from the battery.

Mr. JUSTICE SMITH: I may take it, apart from the question of the effective man, that D and E is Lane Fox pure and simple, with the current going from main to battery, and the other is E—*vice versâ*?—Yes; but the step from one to the other is where the difficulty comes in.

WITNESS was cross-examined at considerable length about the charge and discharge of secondary batteries, and on "earth." A sample of Andrews' concentric cable was handed to him, and extracts were read from a favourable report by the witness on this system. He believed that a very considerable number of largish installations had been insulated, or had been put up upon the Andrews system, and a good many ships.

Other examples having been referred to,

Mr. JUSTICE SMITH: What are we on now?

The ATTORNEY-GENERAL: We are on the question of what I may call the earth return being possible.

Mr. JUSTICE SMITH: I am aware of that; but in Dr. Hopkinson's view the earth return in a large place was impossible, on account of not being able to get sufficient connection with the earth. That would not apply to this at all.

The ATTORNEY-GENERAL: No, it would not apply.

Mr. JUSTICE SMITH: What has Andrews to do with it?

The ATTORNEY-GENERAL: I am not arguing, my lord, but I am going presently to point out to your lordship that this distinction between large and small insulations, which is set up by my learned friend, is no objection to this earth return.

Mr. JUSTICE SMITH: Because what?

The ATTORNEY-GENERAL: Because, supposing that it was a perfectly proper method of uninsulated return, that is to say, by earth——

Mr. JUSTICE SMITH: Do not put in "uninsulated"; say, "earth pure and simple."

The ATTORNEY-GENENERAL: Yes, I will take that—"pure and simple" for a moderate installation—say the one which Dr. Hopkinson suggested the other day. I do not want to cite the authorities now——

Mr. JUSTICE SMITH: I know that; but I want to see what bearing this has as to Andrews, only in order to see that I am following the point which Dr. Hopkinson takes, and which Sir Frederick Bramwell takes, and which is on the face of this case—that when you have an earth return pure and simple you cannot get a connection with the amount of amperes for the electric light; but if you put this, you have got the connection.

The ATTORNEY-GENERAL: Your lordship follows the point, and I will put it to him in two sentences. If there were a difficulty in getting proper earth, owing to the objections you take, would not a band of copper buried in the ground get over that difficulty?—Then you would have got your separate return.

Would not that get over the difficulty at once?—By making an earth connection?

Yes.—Of course it would. You have no earth connection for the purpose of conveying it.

You mean no soil connection?—Yes.

Was it not perfectly well known in 1878 that if your current was sufficiently large to make a difficulty in the size of your earth plate, an uninsulated conductor would do just as well?—I do not know that it was even known that there was a difficulty.

Do I understand you to say that the difficulty would not be apparent as soon as you came to an unwieldy size of earth plate?

Mr. JUSTICE SMITH: I think you may take it upon the evidence that supposing it read "the earth"——

The ATTORNEY-GENERAL: And that it means soil——

Mr. JUSTICE SMITH: Then you have to show a feasibility of working the earth.

The ATTORNEY-GENERAL: No, my lord; with very great deference I say not. I say, respectfully, you must be allowed to have all ordinary electrical equivalents.

Mr. JUSTICE SMITH: That would depend upon whether the specification excludes the others.

The ATTORNEY-GENERAL: Certainly.

Mr. JUSTICE SMITH: I say that is the point.

The ATTORNEY-GENERAL: If the language of the specification is soil, and soil will do for a small one——

Mr. JUSTICE SMITH: There is an end of the case.

The ATTORNEY-GENERAL: Then I say the ordinary electrical equivalents are not only allowed, but must be allowed to be included to deal with the question of a large installation. I cannot argue it now, as your lordship is aware.

WITNESS was cross examined on his patent for the three-wire system, in which it is suggested that the middle conductor need not be insulated. He thought that the word "condenser" in Mr. Lane Fox's letter to *The Times* referred to Leyden jars. He did not think that secondary batteries was a warrantable extension of the meaning.

Dr. HOPKINSON was briefly re-examined by Sir HORACE DAVEY.

Mr. R. E. B. CROMPTON, examined by Sir HORACE DAVEY, said that he had been connected with electrical engineering since the year 1878. He commenced carrying out his first contract in the year 1878. At that time he took to the new profession of electric light engineering. There was nobody in the business, with the exception of Messrs. Siemens and Mr. Wilde of Manchester. He designed the installation at Kensington as an engineer, and carried it out as a contractor in 1886. He took the contract for putting up the electric light in these Courts at the end of 1881 or the beginning of 1882. It was the first large installation of incandescent lighting in England. There were 33 cells, three in parallel. At first, compound dynamos were used. On one occasion the batteries were turned on to three lamps. They burned very brilliantly, and one burst. They then turned on the whole of the lights in the Court, and found that they were all equally brilliant, and would have been quickly destroyed, so they immediately switched them off again. The end connection was altered to the 32nd or 31st cell. For a short time the lamps were about the right brilliancy, but in a few minutes the lamps were again too bright. The next day he tried the experiment of switching on the secondary batteries alone, without the assistance of the dynamos. He then was surprised to find that the lamps were not bright enough—in fact, so dull that the Court was only half lighted. The ultimate fate of the accumulators was that Her Majesty's Office of Works ordered them to be removed and their place to be taken by additional dynamos. He met Mr. Lane Fox within two or three months of the trouble, and he asked him how he accounted for this tremendous change in the pressure which they had observed between the times when the dynamos were parallel to the batteries and the times when the batteries were working alone. He told witness that he attributed it to the cells being bad; he did not say anything about fitting switching apparatus. Two years later he put a battery into his own house. He was attempting to improve accumulators—to get over these difficulties—among others the difficulties of pressure which gave this trouble in the Law Courts. He found out after he had had the battery in his own house that it was

Digitized by Google

impossible—that this difference of pressure was inherent to the lead couple battery, that is the Planté battery or any of the modifications that had been brought out. He found that it could be only mitigated very slightly by increasing the active service of the plates in contact with the electrolyte, and he at once accepted the fact and devised proper switches for switching cells in and out.

The witness then described the construction and details of the Crompton Howell battery, and put in some tests and curves showing the results of an attempt to charge with pressure never exceeding 1 per cent. above the 100 normal. He began with it at 2·14, and then raised the pressure so that it came to 2·160, and a current of 3 amperes commenced to flow. They kept it steady for an hour and fifty minutes. At the end of that time a peculiar action, called "sulphation" of the cell, took place. After 12 hours and 20 minutes they had only got 3 ampere hours into that cell. Only the hundredth part of the capacity into that cell. The object of this test was to see whether they really could get any practicable charge into the battery at all, according to Prof. Perry's proposal. After raising the pressure to 5 per cent., they got altogether 32 ampere hours in 24 hours, so that it would take ten days to charge the battery. The object of the second experiment was to show clearly that this slow charge not only did not fill up a cell, but also exercised a very hurtful effect. When they first commenced, having raised the potential as near as possible 1 per cent., they found 2·243 amperes were entering the cell; twenty minutes later they found that that had fallen to 1·1 amperes. It fell so rapidly that in the first twenty minutes it had halved itself. Ten hours thirty minutes later it had balanced itself so completely that practically no current entered the cell. This experiment was done about six days ago, about two days after Prof. Perry had given his evidence. There was no discharge practically. The cell ran down immediately, with only eleven ampere hours. It had got so sulphated that the whole of its charge had passed away, due to the treatment it had received. He had noticed it always at ending these attempts to make cells do what Mr. Lane Fox wished them to do, that is to say, to float—sometimes discharging a little, sometimes charging a little, and it accounted for the whole of the failures. In five minutes there were 14 amperes discharged. They commenced at the rate of 14 amperes, and they put it up to 20 as quickly as they could, which was the proper discharging rate of the cell—a very low discharging rate for that size of cell—and in thirty-five minutes it had run down practically. The third experiment was an endeavour to charge the battery in 18 hours, being the outside time which could be claimed in the use of batteries on the Lane Fox system.

TUESDAY, MARCH 8TH.

Mr. CROMPTON, recalled and examined in chief by Sir HORACE DAVEY, said he knew of two mechanical means of counteracting the practical difficulty from the rise and fall of the pressure in the charging and discharging other than the arrangement employed at Kensington. They were exact equivalents of it. They might cut off cells, introduce resistance, or introduce a counter electromotive force. There was no hint or suggestion of anything of that kind in the specification. No competent electrician would introduce the means described into Mr. Lane Fox's system without the application of experiment, trial, and ingenuity. It took witness up to 1883 or 1884 before they suggested themselves to either Prof. Perry or himself, or others experimenting in that direction. They could mitigate or diminish, but could not neutralise the rise and fall altogether by any increase in the conducting surface At Notting Hill Gate Station the batteries were five times the size, and they had practically the same rise and fall as at Kensington. The batteries in the Kensington Station never alternately charged and discharged without the use of a switch in the manner which it was suggested Lane Fox's was intended to operate. The first process was charging the main and accumulators up to a pressure of 140 volts. When both switches were at 50, and lights were put on the circuit, the boy, seeing the voltmeter moving down, would sign with his hand, and the engineer would go as fast as he could go; and if he saw the voltmeter not going up rapidly he would run to the sliding switch and raise it as rapidly as he could, turning on several cells. That was in practice the way they met the drop occasioned by the putting on of a load of lamps, *i.e.*, by speeding up the engine at once. After 10 to 12 p.m. they left the battery to act alone. Directly they stopped the engine cells were switched up to 49 say, and a few minutes afterwards to 50, and a few minutes afterwards to 51, and then they would leave it for the night. He tried using the earth, in the sense of the soil, as a return conductor for the purpose of completing the circuit several times. In the year 1879 or 1880 he had a portable electric lighting plant at Henley Regatta, and he thought it a very good opportunity of getting an earth return. They had lights on the Henley Bridge. He took sufficient insulated wire to make only one conductor, and he took a quantity of uninsulated wire for the other conductor. In the first instance he put a coil of the uninsulated wire into the water close by his engine in the River Thames, and connected one pole of the dynamo with it, and connected the corresponding pole of the lamp with another coil of wire, which he threw into the river at Henley Bridge, so that it rested on the bottom of the river. The result was that he could get absolutely no current through the dynamo.

Mr. JUSTICE SMITH: Do you say the earth is not a conductor at all?—I say the water of the River Thames, which is very pure, was practically a non-conductor.

The current was 20 amperes. With a current of 20 amperes they got nothing back to the dynamo. The resistance was so high they got practically nothing. He tested the resistance. On the second test he found the resistance was 10 ohms. He tried at Stanton Ironworks the second class of return by water, complete water pipes, and had great difficulty in getting what he desired. He had used earth in the second sense of a continuous metallic conductor bedded in the earth frequently—the Southend Tramway, for example. In the early stages of the use of his special system of mains he did not strain them sufficiently, and some of the conductors touched the earth at various points. The effect of the current passing by that means to conductors covered with lead was that such leakage as occurred in the house found its way to earth by the outside covering of these conductors; and it was remarkable how quickly the lead was eaten away whenever there was a leakage in the house. They noticed that the corrosion was always confined to the points where there was a change of state, where the pipe passed from a wet place into a dry place—it was entirely confined to the wet place. His general observation was where they had put an outside conductor, not the secondary conductor, but the outside conductor, actually to earth, it had been corroded with extreme rapidity; a few days sufficed to cut it in two. They did not dot their secondary batteries about the mains, as proposed by Mr. Lane Fox, to overcome the resistance at particular points.

Or anything like that way?—Nothing like that way.

Or for that object?—Or for that object; we do the reverse in fact.

And do you use other means for obtaining that object?—Yes.

Those other means being what?—The feeders and pilot wires.

Cross-examined by the ATTORNEY-GENERAL, WITNESS stated that by feeder he meant a wire which took current some point away from the engine-room, which feeder wire was not tapped by lamps till the required point. A pilot wire was a return tell-tale to tell the people in the engine-room whether the voltage had fallen from any cause. It told what the pressure was at the point it came from. Those were the two improvements which were necessitated to a large extent by the size of his system although used in quite small systems.

Now, I put it to you, and I ask you to answer my question without indulging in theory for the moment. Do not the presence of secondary batteries and cells remaining constant at any given position tend to diminish that flicker?—I say, advisedly, they do not. He was examined before the Board of Trade in 1889. The Kensington installation, as it was now used, practically was then in force, but not on as large a scale. They did not have a separate charging dynamo at that time.

Now I want to read three questions and answers, No. 4,516. Evidence given when you were examined on the 10th of April, 1889, by my learned friend, Mr. Moulton: "In your case I believe you use only a small allowance of batteries, because you use them only as regulators, and just for the period of maximum and minimum supply, is not that so? —(*A.*) That is so, yes"?—Yes.

There are three things put to you there, as regulators, and for the period of maximum and minimum supply. Now I ask you, Mr. Crompton, kindly to think carefully, did you not mean, when you gave that answer, you were using the secondary batteries as a fly-wheel or regulator to control the electromotive force?—Not as a fly-wheel or regulator. We use them as reservoirs.

Mr. JUSTICE SMITH: But, my dear sir, look at the question.

The ATTORNEY-GENERAL: Did you not mean then that you used them as a regulation to control the electromotive force?—You said a fly-wheel - not as a fly-wheel—as a regulator for long changes.

As a regulator to control the electromotive force?—As a regulator for long changes.

Is not the only reason why you never want to shift the switch higher than 45 on the discharge because the potential of total number of cells falls below the requisite pressure?—That is the reason, as it falls you shift the switch so as to increase the number of cells.

You put on extra cells to keep up the potential?—Yes.

The fall in the potential is due to the draught current coming out of it is it not?—Yes, it is due to two things.

After reading extracts from Mr. Dobson's remarks during the discussion on Mr. Crompton's Civil Engineer Paper, the ATTORNEY-GENERAL said: You told my lord in chief that you rely on the boy signalling to the man, and the stop-valve being altered. Now I ask you this, whether, when the steam escapes and the steam-valves cannot be altered, these accumulators are not here pointed out as acting as regulators?—Not without the switches. He falls on his second line of defence—his switches –and then proceeds to switch up, and his switch-board is so placed that he can do it.

WITNESS was next cross-examined on his Paper read before the Society of Telegraph Engineers and Electricians.

Questioned as to the charging experiments, WITNESS said he had made the same experiments and repeated them half a dozen times in the last ten years.

Mr. JUSTICE SMITH: How many times, did you say?—I have made the same class of experiments, not exactly on the same lines but with generally the same results, during the last ten years.

In further cross-examination WITNESS said switches such as were necessary for batteries were not known in 1880. His firm might have sold multiple switches at that date. It was a distinct invention using two switches. To detach the charging switch from the discharging switch was an invention. After being questioned as to the Law Courts installation, his opposition to Mr. Lane Fox's disclaimer, and the part he took in the discussion on Mr. Lane Fox's Paper, read before the Society of Telegraph Engineers in 1881, the WITNESS was re-examined by Sir HORACE DAVEY, and the Court adjourned until Monday, 14th inst.

Sir Henry Mance was briefly examined and cross-examined on "earth" on Monday. The Judge stopped further questions, saying that it seemed to him that "the earth" means any return, but is liable to be altered by the context in which it is used. Mr. H. W. Miller, resident engineer at Kensington Court, gave evidence about the details of working, and was cross-examined by Mr. Moulton. Mr. R. S. Erskine, the secretary, was briefly examined by Mr. Wallace, and cross-examined by Mr. Moulton. Mr. Swinburne followed, and brought out one or two new points, introducing the suggestion that Mr. Lane Fox wished to avoid the fall of pressure due

Digitized by Google

to the resistance of the mains by the use of an earth return of small resistance. He had calculated that an earth-plate to take 1,000 amperes would be somewhere between 25 acres and 4 square miles, with one volt at each plate, and that if gas and water pipes were used, about 10 tons of metal would be eaten away in a year.—His cross-examination was continued on Tuesday morning. Mr. Shillitoe, electrician at Hatfield House, gave evidence on the practical use of earth returns; and Mr. Dorner, of Messrs. Siemens Bros., described an attempt to make return by the earth at Lord Armstrong's house at Craigside in 1878. Prof. Kennedy was examined by Mr. Wallace, and described the use of secondary batteries by the Westminster Company. He denied that the battery would sensibly counteract flickering. Mr. B. Drake gave evidence about the use of storage batteries, and was followed by Mr. F. King.—On Wednesday, Mr. King's cross-examination was concluded, and after a short discussion it was agreed that rebutting evidence would not be brought by the plaintiff. Mr. Finlay then made a speech; and it was arranged that the Attorney-General would address the Court to-day (Friday).—The abstract of the report will be concluded in our next issue.

The National Telegraph Works Company (Limited).

The action of Hedges *v.* the National Telegraph Works Company (Limited), of Wainwright-street, Aston, Birmingham (J. Slater Lewis, Manager) came before Mr. Justice North, in the Chancery Division, on Friday last. The action was brought by the plaintiff, on behalf of himself and all the other debenture holders in the Company, for the appointment of a receiver of the property of the Company. The plaintiff was the holder of six debentures of £25 each. Since the notice of motion in this action had been given the Company had passed a resolution to wind up voluntarily. The principal of the debentures had now become payable.

Mr. DRUCE appeared for the plaintiff, and the Company did not oppose.

Mr. Justice NORTH appointed as receiver a gentleman named.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March* 4, 1892.

Long-Distance Transmission of Power.—The long-distance transmission of power in its various phases is now occupying the attention of electrical engineers and capitalists more than at any previous time since the electrical industries came prominently before the public. A number of new problems have been presented in the construction of plants of this character, especially in the far West in the mountainous regions of Colorado and Nevada. It has been found that one of the most difficult features of the work is the construction of a sufficiently durable line, as the obstacles to be overcome are much greater than those met with in any other class of electrical line construction. In the plant at Telluride, Colorado, using Westinghouse alternate-current motors, the power is furnished by a 600ft. waterfall 8½ miles from the line. The construction of the line necessitated an expenditure of $10,000. The generating plant was 9,000ft. above the sea, while the elevation of the motor plant at the mine was 12,000ft. A "hog back" between the two required the carrying of the line to an elevation of 1,400ft. over a single peak. The entire line was inaccessible for nine months in the year, and it was necessary to construct it in the most durable manner possible. Ordinary glass insulators were used; and although the E.M.F. on the line is 3,000 volts, no trouble from defective insulation has been experienced. For a part of the distance it was necessary to carry the line through the densest timber, while at other places projecting rocks and crags had to be blasted out to afford a passage way for the line, which is of No. 5 bare copper wire. The poles for the lines were cut within 100 to 200ft. of the route, but in at least half of the construction it was necessary to blast the holes in which the poles were set.

BOOKS, &c., RECEIVED.

"Taschenbuch für Monteure elektrischer Beleuchtungsanlagen," by S. Freiherr S. Gaisberg. (Munchen and Leipzig: R. Oldenbourg.)

"Secondary Batteries." By J. T. Niblett. (London: Biggs and Co.)

"Year-Book of Science." Edited, for 1891, by Prof. T. G. Bonney, F.R.S. (London: Cassell and Company, Limited.) Price 7s. 6d.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892.

The tenth annual edition of the above well-known annual is now ready, price 7s. 6d.; post free, in the United Kingdom, 8s. 3d; abroad (with the exception of a few countries), post free, 8s. 10d.

The edition consists of between 900 and 1,000 pages, and special care has been taken to make the Directorial division of the book, which has been considerably extended, thoroughly accurate and reliable. In this respect no possible comparison can be made with any similar publication.

To the Handbook division has been added several features which will be found of service to the Electrical and Allied Trades. The Digest of the Law of Electric Lighting has been thoroughly revised and brought up to date, and the most recent Board of Trade Regulations are also included. The various tables and tabulated statements have been remodelled and amplified; and a new feature is the tabulation of valuable information respecting Electrical Limited Liability Concerns.

An important feature is the space devoted to the officials of Foreign and Colonial Governments who have the superintendence of contracts and the giving of orders for electrical plant and apparatus; and as this has been kindly supplied by the various Government departments, it can be relied upon, as can also the particulars given respecting the Home Government departments.

The profession will find "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK a trustworthy work of reference, and purchasers of plant and apparatus may confidently turn to its pages for the names of all the principal firms supplying their requirements. Nearly every firm of any standing in the Electrical and Allied Trades is represented in its advertisement pages.

A digest of the contents of the book will be sent on application.

TENDERS INVITED.—The Committee of the Railway Clearing House are prepared to receive tenders for wiring and fittings for lighting the two blocks of buildings situate in Seymour-street, Euston-square, London, known as the Railway Clearing House. Specifications, schedules and plans may be had, on payment of 21s., from Mr. H. Smart, Secretary to the Committee. Tenders must be sent in by eleven o'clock on Wednesday, the 30th instant. Further particulars will be found in our advertisement columns.

——— The Committee of the Glasgow Town Council on Gas Supply and Electric Lighting invite tenders for providing and erecting engines, dynamos, &c., at their Central Electric Lighting Station, Waterloo-street. Plans and specifications may be seen, and forms of tender obtained, on application to Prof. A. B. W. Kennedy, 19, Little Queen-street, Westminster, S.W., or at the Gas Office, 45, John-street, Glasgow. Tenders must be sent in by the 29th inst., to Mr. J. D. Marwick, Town Clerk, City Chambers, George-square, Glasgow. Further particulars will be found in our advertisement columns.

——— The Bristol Urban Sanitary Authority invite tenders for various works for the central station at Temple Back. Plans and sections may be seen at the offices of Mr. Henry Williams, 21, Clare-street, Bristol. Copies of specifications and forms of tender may be seen and obtained at the offices of the Sanitary Authority, on and after Friday, March 25th. Tenders must be delivered at the offices of the Sanitary Authority, 51, Prince-street, Bristol, by Friday, April 8. Further particulars will be found in our advertisement columns.

APPOINTMENT VACANT.—The Corporation of the City of Londonderry require the services of a competent electrical engineer to advise on the electric lighting of the City. Applications, with copies of testimonials, &c., must be sent in, on or before the 30th instant, to Mr. R. N. Chambers, Town Clerk, The Guildhall, Londonderry,

SALE BY AUCTION.—Mr. Geo. N. Dixon will hold an important sale of contractor's plant at Fallowfield, near Manchester, on Wednesday, the 30th inst., and following day. Amongst other things a complete Gülcher electric lighting plant will be offered for sale.

MESSRS. NALDER BROS.' CATALOGUES.—We have received two price lists recently issued by this firm, the one of electrical and other similar instruments, and another of ammeters, voltmeters, and resistance frames. These lists illustrate many of the most recent and improved forms of galvanometers, keys, resistance boxes, electrometers, and other testing and measuring instruments. Hardly any old-fashioned patterns are included, and the illustrations show all the prominent details clearly. The typography of this catalogue is very excellent.

Digitized by Google

REMOVAL NOTICE.—Messrs. Dorman and Smith announce that they have now removed into their new premises at Ordsal Station Electrical Works, Salford, Manchester, where all communications and goods are to be forwarded: the above is the only address of the firm. Messrs. Dorman and Smith are manufacturers of all kinds of electric light accessories.

THE METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—This Company announce that the engineer's offices are removed from 4, Waterloo-place, S.W., to premises adjoining the Manchester-square Station, and that on and after March 18th all communications should be addressed to 17, South-street, Manchester-square, London, W.

MACMAHON'S PATENT ELECTRIC CHECK SYSTEM (LIMITED).—Mr. P. T. Travers. of 27, Albemarle-street, W., has been appointed liquidator in the voluntary winding-up of the above Company.

INSTITUTE OF MEDICAL ELECTRICITY (LIMITED), (IN LIQUIDATION). Mr. J. W. Biggs, of 12, Delahay-street, S.W., announces the first and final dividend of 7s. 11¼d. in the £ in this matter.

ISLE OF MAN INTERNATIONAL EXHIBITION, 1892.—Mr. George North, M.I.M.E., of 90, Queen-street, London, E.C., has been appointed representative for London and the South of England for the above Exhibition, which will be opened on July 4th next.

MESSRS. W. H. ALLEN AND CO.—The ss. "Ophir" has been fitted with 850 sixteen candle-power lamps, together with arc lights for the Suez Canal. The engines and dynamos are both of Messrs. Allen and Co.'s make, and consist of four sets of compound twin engines of 40 H.P., driving direct a compound-wound dynamo with drum armature. The work was carried out in four months from date of order.

CRYSTAL PALACE ELECTRICAL EXHIBITION.—Additional pages relating to the exhibits at the Crystal Palace have recently been added to the catalogue, and will be found useful to visitors. These pages are called "A Guide to the Crystal Palace Exhibits"; but although several useful exhibits of electrical publications are included in the Exhibition, no reference is made in the Guide to the position of the stands. So far as *The Electrician* Company's stand is concerned, we have pleasure in supplying the omission by notifying our readers that they can obtain electrical publications at Stand No. 43A, near the High Level Entrance.

BLOCKLEY ELECTRIC LIGHTING AND MANUFACTURING COMPANY (LIMITED).—We learn that the contract for the erection of lightning conductors for Winchester Cathedral has been entrusted to this firm.

ERNEST SCOTT AND MOUNTAIN (LIMITED).—This firm send us a copy of their Engineering Catalogue, which includes triple-expansion engines for mills, gun-boats, launch engines, Admiralty and pattern feed, fire, and bilge pumps, air and circulating pumps, workshop engines and condensers, forced draught fans, hydraulic pumps, and illustrations of the larger class of gun-metal and brass castings which their foundry is capable of producing.

THE NEW TELEPHONE COMPANY (LIMITED).—A circular is issued under the auspices of the Directors of the Pioneer Telephone Company, announcing that the new Telephone Company will shortly commence operations, and promising telephone users "subscriptions at little more than half those now charged in London." The new Company's system "is to have twin wires, and to be fitted with the newest switching apparatus."

RUBBER.—Rubber receipts at Para during January are reported to have been 3,030 tons, an amount much in excess of the usual receipts.

THE POOLITE MUSICAL SOCIETY.—The first smoking concert was given by the above Society in the dining saloon, Broad-street Station, on Tuesday evening, the 8th inst., when about 200 of the *employés* and friends of Messrs. Poole and White (Limited), (of Bread-street, City, and King's-road, Camden Town) assembled. A first-class programme had been arranged, and was successfully carried out.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

February 18, 1892.

3,145. J. WHITEHEAD. Birmingham. Improvements in electric globe and shade holders.

3,161. J. H. AHRENS. London. Indicator of railway stations by electricity.

3,211. F. BROWN. London. An improved electric switch.

3,212. F. BROWN and P. COLLINS. London. Improvements in the application of electric light to roundabouts, and the like, which improvements are also applicable to advertising purposes.

February 19, 1892.

3,223. G. WILSON. Sheffield. Improvements in apparatus for electrically signalling the engine-drivers or the guards of trains.

3,233. W. S. RAWSON, C. S. SNELL, and WOODHOUSE AND RAWSON, UNITED (LIMITED). London. Improvements in apparatus to be used in connection with electrically driven machines.

3,234. C. S. SNELL, and WOODHOUSE AND RAWSON, UNITED (LIMITED). London. Improvements in electrical switches suitable for use in connection with electric launches and the like.

3,240. J. LANG. London. Improvements in materials or compounds to be used in the manufacture of moulded articles, such as door handles, insulators for electrical purposes, boxes, toys and other articles of the like kind.

3,244. W. MITCHELL. London. Improvements in the method of and apparatus for lighting by electricity circular switchback railways.

3,283. J. H. TONGE, L. CLARK, and MUIRHEAD AND COMPANY (LIMITED). London. Improvements in electric arc lamps, specially applicable to search lights.

3,291. E. PAYNE. London. Improvements in tubular electrical conductors.

3,297. C. VOGT. London. Improvements in electric meters.

3,300. C. J. BARLEY. London. Improved means for effecting the connection of electrical conductors.

February 20, 1892.

3,314. C. B. BURDON. Hornsey. Improvements in and relating to the utilisation of alternating currents of electricity for producing motive power, for charging storage batteries, and for other electro-mechanical and electro-chemical operations.

3,366. T. L. HEMMING. Birmingham. Improvements in dynamo-electric machines.

3,379. W. R. RENSHAW. London. Improvements in stoves applicable especially to thermo-electric stoves.

February 22, 1892.

3,423. Sir C. S. FORBES, Bart. London. Improvements in telephones.

3,427. C. A. J. H. SCHRODER and H. E. R. SCHRODER. London. A new carbon electrode for electric arc lighting, to be called the "electric torch."

3,443. G. HUGHES. London. Improvements in electrie arc lamps. (C. H. O. Japy and O. Helmer, France.

February 23, 1892.

3,472. R. J. BOTT. London. Improvements relating to incandescent lampholders.

3,488. A. C. HAMILTON. London. An improved method of coiling-up conductors of portable electric lamps.

3,513. G. D. DAVIS. London. Improvements in diaphragms for electrical cells.

3,514. G. D. DAVIS. London. Improvements in the process of electrolysing alkaline salts.

3,521. O. IMRAY. London. Petroleum lamp with electrical igniting device. (C. Wasmuth, Germany).

3,522. O. IMRAY. London. Improvements in electrical igniting devices for gas lamps. (C. Wasmuth, Germany).

3,523. O. IMRAY. London. Improved galvanic element. (C. Wasmuth, Germany).

3,538. R. J. CHARLETON and H. WALKER. London. Improvements in distributing and controlling electric currents in mines or other dangerous places.

3,542. H. H. LAKE. London. Improvements in telephone apparatus. (W. Gray, United States).

3,559. S. W. KIMBLE. London. Improvements in the manufacture of compositions for insulating or other purposes.

3,560. S. W. KIMBLE. London. Improvements in trolly-wire hangers and other appliances for use in overhead electric railway systems.

3,561. S. W. KIMBLE. London. Improvements in trolly wheels for electrically propelled vehicles.

3,562. S. W. KIMBLE. London. Improvements in the construction and mounting of electrical connecting devices upon their non-conducting supports.

3,569. A. CAY, trading as J. STEVENS AND SON, and also as STONE, FAWDRY AND STONE. London. Improvements in the glass chimneys, globes, and shades of electric and other lamps.

3,572. A. F. LAW. London. Improvements in apparatus for electrically operating or controlling type-writing machines, type-setting machines, or apparatus for recording, indicating, or signalling. (E. F. Law, Russia).

February 24, 1892.

3,595. F. MOORE. Birmingham. Improvements in shades and reflectors for incandescent electric lamps.

3,631. F. BIDTEL. London. Improvements in the manufacture of compound and insulated wires.

February 25, 1892.

3,654. E. RICHTER. Manchester. Improvements in electric burglar alarms.

3,707 J. C. MEWBURN. London. Improvements in electric arc lamps (P. Sée, France).

Digitized by Google

3,714. D. MacPherson. London. Improvements in safety switch frogs.
3,719. A. B. Burnand. London. Improvements in apparatus or switches for controlling electric currents.
3,724. H. W. Sander and M. D. Memmell. London. An improved electric arc lamp.

February 26, 1892.

3,750. Sir C. S. Forbes, Bart. London. Improvements in microphones and in apparatus connected therewith.
3,758. W. F. Parkinson. Newport. Improved holder for incandescent electric lamps.
3,801. L. W. Winnall and W. H. Winnall. London. Improvements in electric bells.

February 27, 1892.

3,873. H. C. Donovan. London. Improved insulating media for electrical conductors.
3,875. C. Coerper. London. Improvements in and relating to electric motors.
3,881. K. Kahabka. London. Improvements in electrical accumulators.

February 29, 1892.

3,887 F. E. Stuart. Twickenham. A system of sending and receiving signals on telephone lines for use in fire brigades and other purposes.
3,919. W. S. Rawson and Woodhouse and Rawson United, Limited. London. Improved method of preparing incandescent lamps.

March 1, 1892.

3,951. J. S. Lewis. Ealing. An improved telephonic transmitter diaphragm.
3,970. B. J. B. Mills. London. Electro-magnetic machines. (R. Lundell. United States.)
3,971. B. J. B. Mills. London. Improvements in power-transmitting devices, especially applicable to the electrical propulsion of vehicles. (E. H. Johnson, United States.)
3,991. G. H. Nunn. Manchester. Improvements in electrical call and indicating apparatus.
3,996. W. P. Thompson. Liverpool. Improvements in galvanic electric adhesive plasters. (J. W. Shults, United States.)
3,997. C. H. Smeeton and H. Page. London. Improvements in reflectors for electric lamps.
4,003. W. S. Rawson, W. P. Gallwey, and Woodhouse and Rawson, United, Limited. London. Improvements in electro-magnetic tools.
4,010. W. C. Lockwood. London. Improvements in telephones.
4,015. H. H. Lake. London. Improvements in electrical devices for stopping and starting horses. (The Holson Electric Harness and Supply Company, United States.)
4,017. H. H. Lake. London. Improvements in electric measuring instruments. (E. Weston, United States.)
4,025. W. H. Miller. London. An improved means of effecting electrical communication through the medium of a clock or similar apparatus.

March 2, 1892.

4,068. J. B. S. Booth and E. J. Falconer. Manchester. Improvements in telephones.
4,097. E. C. Russell. London. An improvement in the construction of electric arc lamps.
4,103. R. Goodwin. Dublin. Electro-deposition of aluminium on metals.
4,111. J. M. Glover. London. An improvement in electro-magnetic time and date-stamping machines.
4,112. J. M. Glover. London. An improvement in electro-magnetic postal, cancelling, time and date-stamping machine.
4,113. J. M. Glover. London. Improvements in electro-magnetic time and date stamps.
4,125. F. T. Hollins. Leytonstone. Improvements in electrical circuit arrangements and apparatus for telegraph message signalling.
4,134. C. E. Kelway. London. Improvements in electrical visual signalling apparatus.
4,152. W. J. Herdman. London. Improvements in electro-therapeutic apparatus.
4,154. E. Viarengo. London. Improvements in electric batteries.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1891.

4,479. Morgan-Grenville. Electrical conductors.
4,881. Clark. (Sigmund Schuckert and Company). Electric tramways.
5,461. Dickinson. Electric traction.
5,715 Pitt (Davidson). Insulating electrical conductors.
6,029. Walenn and Timmis. Electro-depositing copper, &c.
6,030. Walenn and Timmis. Electro-depositing copper, &c.
6,318. Mitchell. Medico-electric batteries.
6,492. Barter. Electric glow lamps.
17,310. Von Orth and Breslauer. Electric signalling.
19,370. Dunand. Incandescent electric lamps.

1892.

278. White and Allam. Electrical conductors.
645. Gendron. Electric welding.
798. Siemens Bros. and Co., Limited (Siemens and Halske). Electrical conductors.

COMPANIES' MEETINGS & REPORTS.

Direct Spanish Telegraph Company (Limited).

The following is the report and accounts of the Directors of this Company for the half-year ended 31st December last, to be presented at the general meeting of shareholders, to be held on Tuesday next, the 22nd inst., at Winchester House, E.C., at 12 o'clock.

The accounts for the half-year ended 31st December show, after providing for debenture interest, a balance to the credit of profit and loss of £5,028. 12s. 11d.

The traffic receipts show a decrease of £2,214. 4s. 9d. as compared with those for the corresponding period of 1890. The falling off in the receipts is chiefly due to the reductions of rates which the Company had to submit to at the International Telegraph Conference held at Paris in 1890, and which came into force on the 1st of July last.

The working expenses are £17. 4s. 5d. in excess of those for the corresponding period of last year.

The Company's cables, and the land-lines in connection with them, have with one exception continued in good working order throughout the half-year; a serious fault having suddenly developed, on the 23rd of October, in the Falmouth-Bilbao cable. The cable was repaired by the Eastern Telegraph Company's cable-ship "John Pender" on the 27th November, since which date the cable has worked well. The prevalence of bad weather, and the quantity of new cable inserted, brought the cost of the repairs to £4,050. 17s. 7d., including the value of cable from our stock. This amount has been paid by transferring £1,674 5s. 3d., the balance of the contingencies account, and by taking £2,376. 12s. 4d. from the reserve fund, and it is intended to repay this amount to the reserve fund out of future profits.

Some exceptional expenditure was incurred during the past half-year, the principal items being on account of the removal of our station at Marseilles to the new post office in that town, and special repairs effected on the underground cables at Falmouth and at Bilbao.

Of the balance of profit and loss, £2,500 have been put to the reserve fund (which now amounts to £26,445. 19s. 4d.), leaving £2,528. 12s. 11d. Out of this amount the Directors recommend the payment of the dividend at the rate of 10 per cent. per annum on the preference shares, and a dividend at the rate of 4 per cent. per annum (free of income tax) on the ordinary shares, making, with the previous distribution, 4½ per cent. for the year 1891. A balance of £31. 13s. 4d. is carried forward. The dividend warrants will be issued on the 1st of April next.

Sir James Anderson and Mr. Denison Pender are the Directors retiring by rotation, and offer themselves for re-election. The auditor, Mr. Herbert R. Duke, retires, and offers himself for re-election.

Gülcher (New) Electric Light and Power Company (Limited).

The following report has been issued by the Directors of this Company, and will be submitted to the shareholders at the meeting to be held at Winchester House, E.C., on Monday, the 21st inst., at 12 o'clock.

The report and balance-sheet are for the twelve months ended June 30, 1891. The Directors have postponed the presentation until now in order that the Chairman might be able not only to interpolate such of the New Zealand accounts as are properly chargeable to the current year, but also to explain to the shareholders the results of his journey to the colony. It will be seen by the balance-sheet that the public lighting installation at Wellington (which was completed early in 1890) had cost the Company £13,486. 13s. 3d. to erect. This installation, which was producing a revenue of £1,750 per annum, reducible in three years to £1,600 per annum, was costing the Company nearly £1,300 per annum to maintain; and, as was pointed out in the last report, the commercial success of the undertaking depended entirely upon the provision of further capital for the supply of light to private consumers.

A syndicate which had then already been formed for this purpose, and to take over the public lighting business of the Company in the Colony, stipulated that Parliamentary powers from the New Zealand Legislature should be first obtained at the expense of the Company. The Corporation of Wellington had also set up a claim to be paid a sum, amounting to about £530 per annum, for water, which they alleged that the Company used in excess of the quantity which the Corporation had contracted to supply, and serious litigation appeared to be imminent. Under the circumstances, it was resolved that the Chairman should go to New Zealand, at the joint expense of the Syndicate and the Company, to settle, if possible, the disputes with the Corporation, and to apply for the necessary Parliamentary powers to enable the Company to sell its installation and the benefit of its contract to the Syndicate.

The Chairman's journey, although protracted far beyond anticipation, has been completely successful. The dispute with the Corporation has

Digitized by Google

been satisfactorily arranged; Acts of Parliament, not only for Wellington but for Christchurch and Auckland, have been obtained; and the Corporation have assented to the sale by the Company of the Wellington Public Lighting Installation to the Syndicate. Could the proceeds of this sale be properly brought into the present year's accounts, the balance-sheet would show a profit of £3,000, or thereabouts, instead of a loss of nearly £1,200. The Acts, however, were not obtained until the end of September, and the final arrangements with the Corporation were not arrived at until November 26, 1891, so that the beneficial results of the Chairman's journey cannot appear until the next balance sheet is issued.

The particulars of the contracts entered into, and of the arrangements made with the Corporation of Wellington, will be supplied at the general meeting, when a detailed profit and loss account will also be submitted to the shareholders.

With regard to the loss shown upon the year's trading, this is distinctly traceable to the depression which fell upon business in England in the last three months of 1890 and the first six months of 1891, in consequence of the financial crisis in the City. For the first time during the last nine years the year's receipts from sales in England have decreased, and during the nine months above referred to they decreased by £2,500, while the business in New Zealand was temporarily at an enforced standstill. Since then the sales in England have again improved, and a new field has been open in the colony, which promises to be a large and permanent customer of the Company.

An agency was also opened in Italy last autumn, and the City of Genoa is already partly lighted by our Company. This agency also promises to prove an increasing business.

Since the last general meeting the Directors, under the powers conferred on them by the Articles of Association, have elected Captain W. S. Levett, a duly qualified shareholder, to a seat on the Board. Mr. Grëwing and Captain Levett retire by rotation from the Board, but being eligible, offer themselves for re-election. Mr. Russell Day, the auditor appointed at the last general meeting, also retires, but offers himself for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, pages 303-322, *and in other parts of that book.*]

ASSINIBOIA IMPROVED LANDS (LIMITED).—Among the objects of the above-named Company, which was registered on March 8, 1892, with a capital of £50,000, in £5 shares, is included that of constructing, using, working, and carrying on railways, tramways, waterworks, gasworks, telegraphs, telephones, electric light, heat and power works, and undertakings of a similar kind.

CONCESSION AND INVESTMENT SYNDICATE (LIMITED).—This Company was registered on March 9, 1892, with a capital of £2,000 in £1 shares, by G. B. Bruce Paton, 20, Bucklersbury, E.C. The objects are to purchase or otherwise acquire a controlling or other interest in gas, water, and electric light companies in the United States of America, the British Colonies, or elsewhere; to adopt and carry out agreements for the acquisition of any concessions, rights, or interests relating to any gas, water, or electric works, businesses, and concerns in the United States of America, Canada, and elsewhere, and to maintain, manage, carry on, work, develop, lease, or exchange, any of the above-named businesses. Registered office: 20, Bucklersbury, E.C.

COSMO GEAR COMPANY (LIMITED).—This Company was registered on March 7, 1892, with a capital of £10,000, in £1 shares. Among the patents acquired is one for anti-friction wheels (No. 16,649, 1891) for driving gear for electric cars.

D. W. BARDILL AND COMPANY (LIMITED).—This Company was registered on March 8, 1892, with a capital of £8,000, in shares of £5 each, as manufacturers and dealers in chemical and other preparations, and electrical, chemical, photographical, surgical, and scientific apparatus and materials at Derby and Burton-on-Trent.

HAYCRAFT AND SON (LIMITED).—This Company was registered on March 12, 1892, with a capital of £10,000, in £1 shares, to carry on business as ironmongers, ironfounders, iron and steel merchants, manufacturers, mechanical engineers, braziers, coppersmiths, electro-platers, electricians, electric light engineers, lamp makers, bellhangers, bell manufacturers, &c., at Deptford and Lewisham.

METALLIC TUBE AND FLASK COMPANY (LIMITED).—This Company was registered on March 9, 1892, with a capital of £50,000, in £5 shares, as manufacturers of and dealers in all kinds of tubes, chemicals, medical, electrical, and chemical apparatus, and fittings of all kinds, &c. The business to be acquired is that of Messrs. Taylor and Challen (Limited), at Wiggin-street, Birmingham.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—The annual return of the above-named Company, made up to February 12, 1892, was lodged at Somerset House on March 11, 1892, by Mr. Thomas Weaver, of 26, Old Broad-street, E.C. The nominal capital is £7,000,000 stock, all of which is fully paid.

BRITISH ELECTRIC INSTALLATION CONTRACTORS (LIMITED).—The statutory return of the above-named Company, made up to February 25, 1892, was filed on March 1, 1892. The Company was registered on October 12, 1891, with a capital of £20,000, in £5 shares. At the time of making up 242 shares had been taken up, of which 100 had been issued as fully paid. Upon the remaining 142 the full amount had been called, resulting in the payment of £575, and leaving £135 in arrears. No agreements for the acquisition of any business, contracts, plant, &c., have been filed. Registered office: 1, Angel-street, Worcester.

BROMPTON ELECTRIC FITTINGS COMPANY (LIMITED).—The second annual return of the above-named Company, made up to December 21, 1891, was filed on March 2, 1892. The Company was registered on April 20, 1889, with a capital of £2,000, in £1 shares, to acquire, promote, carry on, and extend the business of designing and manufacturing art metal fittings for electric light, gas, &c., and to manufacture and supply electric and other bells, heating apparatus, &c. At the time of making up 1,050 shares had been taken up, the full amount and all calls (£1,050) paid. The principal shareholders are B. Gee, electrical engineer (50); C. F. Tufnell, of Lloyd's, E.C., civil engineer (250); B. Gibson, of 1, Upper Westbourne-terrace, W. (250); F. R. Reeves, of Springfield, Little Heath, Potter's Bar (94); and John F. Albright, of 146, Brompton-road, S.W., engineer (400). Registered office: 146, Brompton-road, London, S.W.

CHLORIDE ELECTRICAL STORAGE SYNDICATE (LIMITED).—The registered office of this Company is 13 and 14, Abchurch-lane, London, E.C. (filed on February 20, 1892.) The Company was registered on December 12, 1891, with a capital of £262,500, in £1 shares (of which 250,000 were preference and 12,500 ordinary shares), and full particulars were published in *The Electrician*.

DEVON AND CORNWALL ELECTRICITY SUPPLY COMPANY (LIMITED).—The above Company was registered on June 28, 1889, with a capital of £100,000, to carry on the business of an electric light company. At the date of the last return (January 3, 1889), 42 shares had been taken up, the full amount called, and all calls (£210) paid. The Board of Trade having revoked the Provisional Order acquired by this Company, and no office (without which no business is allowed to continue) having been filed, it may be considered, we understand, that the Company has ceased to exist.

GÜLCHER (NEW) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of the above Company, made up to December 31, 1891, was filed on March 9, 1892. The Company was registered on February 28, 1888, with a capital of £70,000, divided into 50,000 preference and 20,000 deferred shares of £1 each. At the time of making up (December 31, 1891) all the shares had been taken up, and the deferred shares had been issued as fully paid. Upon 12,277 of the preference shares the full amount had been called, and upon the remaining 37,723 preference shares 10s. per share had been called, resulting in the payment of £36,650. 1s. 4d., and leaving £175. 18s. 8d. in arrears.

NEWCASTLE AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of the above-named Company, made up to February 29, 1892, was filed on March 9th. The Company was registered on January 14, 1889, with a capital of £50,000, in £10 shares. At the time of making up (February 29, 1892) 3,075 out of the 5,000 shares had been taken up. Upon 2,138 shares £8 per share had been called, upon 430 shares £6 per share had been called, and upon the remaining 507 shares £4 per share had been called, resulting in the payment of £21,691, and leaving £18 in arrears.

CITY NOTES, &c.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—Particulars will be found in our advertisement pages of the issue of Four and a-Half per Cent. Perpetual Debenture Stock in this Company to the amount of £125,000 at the price of £101 per centum, for the purposes of redeeming the existing £75,000 Six per Cent. Mortgage Debentures of the Company and of providing additional capital for the increasing business. The interest upon these debentures is payable on the 1st March and the 1st September, the first interest for a full six months being made on the 1st September next. The present issue is made by the Electric and General Investment Company, Limited (who are trustees for the Debenture Stockholders), and is payable as follows: 10 per cent. on application, 41 per cent. on allotment, and 50 per cent. on the 1st of May next. As is well known, the Brush Electrical Engineering Company was formed in 1889 to take over the old business of the Anglo-American Brush Corporation, and also of the Falcon Engine and Car Works (Limited). The gross profit shown in the annual report, issued in September last for the year ending June, 1891 (exclusive of any profit from the business accruing to the Brush Company from its interest in the City of London Syndicate), was £39,916, and the actual value of the Company's assets, British and foreign, show a surplus of liabilities of nearly half a million sterling. The present debenture issue is secured by deposit of debentures and a trust deed, and will operate, as a first charge, as a floating security upon the whole undertaking and property of the Company (with the exception of the Vienna business, which is subject to a contemplated re-arrangement). The subscription list opened yesterday, and closes on or before Monday next at 4 p.m. for London, and 11 o'clock on the following day for the country.

CALIFORNIA GAS, WATER, AND ELECTRIC LIGHTING COMPANY SYNDICATE (LIMITED).—This Syndicate, which was formed in December last, is asking for a capital of £30,000 in £1 shares for that portion of its concession which it is proposed to transfer to the Los Angeles City and County Water Syndicate. Persons wishing to subscribe, or requiring particulars, can apply to Mr. G. B. Bruce Paton, 20, Bucklersbury, London, E.C.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the ten weeks ended Friday, the 4th inst., amounted to £33,917, and for the week ending 11th March £2,872. This Company's receipts will be published weekly.

Digitized by Google

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended March 13th were £676, as against £749 in the corresponding period of last year, showing an increase of £127. The total receipts to date, from January 1st, 1892, are £8,830, against £7,714, an increase of £1,116.

EUROPEAN SIMS-EDISON ELECTRICAL TORPEDO COMPANY (LIMITED). Major-General Alexander H. Elliot, C.B., and Captain H. F. Twynam have joined the Board of this Company.

ISLINGTON ELECTRIC LIGHT COMPANY (LIMITED).—"We (*Financial News*) learn that this Company is being formed with a capital of £250,000, and subscriptions will shortly be offered to the public. Sir Frederick Abel has been invited to join the Board, and the enterprise is said to have secured influential support."

SIAM ELECTRIC LIGHT COMPANY (BANGKOK).—This Company has, we understand, gone into liquidation.

FOOTBALL.—SILVERTOWN *v.* SIEMENS BROS.—The return match between the staffs of these firms was played at Charlton Park on Saturday last, and resulted in a win for Siemens Bros. by two goals and a try to nil. The first half of the game was pretty evenly contested, neither side scoring. At the invitation of Mr. Siemens, both teams dined in the evening at the Holborn Restaurant.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 723.—Vol. XXVIII. FRIDAY, MARCH 25, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The report and accounts of the London Electric Supply Corporation, which will be found in another column, call for little remark except at the hands of the shareholders, who meet to-day to stomach them with what appetite they can. The engineer's report states that during the autumn considerable difficulties were experienced in working at 10,000 volts; and there were occasional failures of the dynamos, transformers, and trunk mains, "many of which were due to the present arrangements for working the machines in parallel." Measures are, however, being taken by which, it is believed, these difficulties will be overcome.

The accounts show a total expenditure up to date of more than three-quarters of a million sterling, some £100,000 of which was expended during 1891. Deptford, with its plant and machinery, has cost no less than £280,000; mains have absorbed £148,000; and electrical instruments (not including meters) account for over £12,000. The sales of current by meter at 7¼d. per B.T.U., realised £13,783, which means that 456,265 units were sold. The "sheer cost" of production therefore comes to 5¼d. per B.T.U.; but adding distribution and management expenses the B.T.U. which was sold at 7¼d. cost the vendors nearly a shilling. It is interesting to note that while mains have absorbed no less than 45 per cent. of the Westminster Company's outlay, they only account for 20 per cent. in the case of the Deptford scheme.

The 6¾d. for distribution and management can, of course, be reduced almost in inverse proportion to the increase in the output, and it must be remembered that economy in this respect was held to be the strong point of the London Electric Supply Corporation; but the St. James's and Pall Mall Company spend only 2¾d. on this item. The "sheer cost" will, of course, be reduced also as time goes on, but with the large generating units, a steady load will be needed. The plant which is already arranged for, including the large dynamos which are partly finished, will suffice for just ten times the present number of lamps connected, while the building will provide room for as much again. The day may come when the London Electric Supply Corporation will supply current at 4d. per unit, but the progress towards that result is very slow.

The details of cost of electric light in mills, which will be found in our Notes columns, and for which we are indebted to the *Engineer*, should encourage mill owners as well as proprietors of other large establishments to carry out their own lighting. It is almost impossible to arrive accurately at the cost, especially when so few lamps are in use as in the present case. It is as easy to burden the expenses with heavy items of depreciation as it is to overlook cost of labour when part of a man's time only is employed. We have heard of a case in which the proprietor of a large mill, in estimating the cost of electric lighting, put down a proportion of interest and depreciation of the main chimney shaft and wear and tear of coal waggons, and satisfied himself that the expense would be five or six times that of gas. There are many, on the other hand, who say that electric light costs them practically nothing but lamp renewals, since this is the only item which appears on their books.

Much has been heard lately about oil as an insulator; but it was not until near the close of the discussion on Prof. Hughes' paper that attention was called by Prof. Ayrton to the important distinction between true resistance, opposition to spark discharge, and surface resistance. Mr. Gray and Mr. Cuthbert Hall were the only contributors to our knowledge of the true resistance, which has little if anything to do with sparking distance. The high sparking distance has led many people to think that oil is an extremely good insulator; and it has naturally been imagined that jute cotton or hemp, which have been used as mechanical separators, were the weak points of the system. It has, however, been pointed out that dry cellulose is one of the best possible insulators, and that the function of the oil is not to insulate the fibre, but to keep it dry. This throws an entirely new light on the question, and ought, we think, to give more confidence in the system than it has hitherto received. The surface leakage is, as Prof. Ayrton points out, a totally different matter, and concerns what are known as "oil insulators," though accurate measurements would be of little value for practical work, since the surface is liable to become dirty. The healing properties after a spark discharge must, of course, be completely different when a Wimshurst machine and an alternating dynamo and transformer are used.

In a Paper on Choking Coils, just read before the Physical Society, Prof. Perry upheld the much-debated theory that the loss of energy in transformers caused by hysteresis was

Digitized by Google

very small, and implied that most of the losses which occurred were due to eddy currents. This view will find little favour among engineers until it is supported by more tangible evidence than is supplied by FOURIER's theorem; at the same time Prof. PERRY is probably right in emphasising the importance of eddy currents. It seems generally believed that if the iron be well laminated, the losses due to eddies are negligibly small. The losses due to this cause are, however, quite appreciable even in the best transformers, and the tendency of eddy currents to alter the distribution of the lines of force, causing them to be denser in some parts of the core than in others, may perhaps alter the hysteresis losses. The discrepancies which exist between the calculated and experimental values of the efficiency of various transformers seem to point to the fact that the irregular distribution of the lines of force, owing to magnetic leakage or other causes, affects, to an appreciable extent, the power lost in hysteresis.

THE question turned up in the course of the LANE-FOX case whether, supposing it was feasible in 1878 to use an earth return the intervention of the Board of Trade would "smash up the patent." The converse problem arises in the ingenious "double sealing" patent of Mr. FERRANTI. The Board of Trade have ordered that, "where any alteration is made in any certified meter, or where any such meter is unfixed or disconnected from the service lines, such meter shall cease to be a certified meter unless and until it be again certified." These regulations are to be enforced by the affixing of seals after certification; and Mr. FERRANTI has boldly patented a method of arranging these seals, which, if not the only practicable plan, is one which will require some ingenuity to evade. The cover or case of the meters, which are illustrated on p. 537 of the present issue, are fastened to the body of the instrument by screws which are sunk a little below the level of the case. The seals are fixed to these screwholes after certification, and the meter maker cannot afterwards get to the working parts. A recess is made in the lower part of the meter for the terminals of the cables; these having been attached, a cover is screwed on by the supply company, and seals are fixed by them, which prevent any tampering on the part of the consumer.

AT a recent meeting of the Paris Municipal Council, M. Lyon-Alemand, in the name of the Third Committee, asked for a vote of 40,000frs. to meet the increased expense consequent on the substitution of coke for coal at the Halles central station. He remarked that the Committee could not blame the officials for having conformed to a vote of the Municipality, but the Committee nevertheless felt obliged to remark that the cost of production of the electrical unit was thereby increased. Some few months ago, the Municipal Council was seized with a sudden desire to mitigate the smoke nuisance in Paris. It was, however, pointed out that the Municipality's own chimney at the Halles was one of the worst offenders in Paris, and that pending the discovery of the perfect smoke annihilator, only the use of coke would enable the Municipal Council to prosecute delinquent manufacturers with a clear conscience. This praiseworthy determination to first set its own house in order, and then by the sweet persuasion of the law to oblige others to do likewise, has thus cost the Municipality an altogether respectable sum.

THE Havre jeweller who warms his shop with an alternate-current transformer affords another example of the interest which is being taken in electrical heating for domestic purposes. Without going so far from home, we could point out a transformer chamber in London, constructed, as it should be, of thoroughly fire-proof materials, where a thermometer hung on the brick wall indicates 115° Fahr.

Telephonic Changes.—The business of the Mutual Telephone Company was taken over by the New Telephone Company on Wednesday last.

Erratum.—On p. 510 of our last issue, in the Note headed "A Mountain Electric Railway," for "36 cubic feet per second," read "706 cubic feet per second."

The Belgian Government and the Telephones.—It is officially announced that the Belgian telephones will be taken over by the Government on January 18th next.

Schmalkalden.—The Trusenthal waterfall, which gives a minimum power of 150 H.P., is about to be utilised for lighting the town of Schmalkalden by electricity.

Copper.—According to *The Statist* a combination is in negotiation among the big American and other copper producers to restrict the world's supply to the demand.

India-Rubber.—A company has been formed for the purpose of growing india-rubber on a large scale in Mexico. About 100,000 trees are to be planted in the State of Sinaloa.

Manila.—The Manila municipal authorities offer a concession for twenty years and a subsidy of £12,000 a year in reference to the electric lighting of the town. The contractor is to be at liberty to supply private houses.

Storage Battery Plate Capacity.—According to some tests of Prof. Dufour, of Lausanne, the capacity in ampere-hours of the following storage battery plates per lb. is as follows:—Huber, 6·6 E.P.S. 3·2; Reckenzaun, 3·27; Farbaky and Schenk, 5·1.

Electric Heating.—According to *l'Industrie Electrique*, a Havre jeweller, who has an alternate-current transformer installed in the basement underneath his shop, has placed an iron grating over it, and in this way warms his premises largely at the electricity supply company's expense.

Sydney, N.S.W.—Mr. Arthur C. F. Webb, M.I.E.E., has recently been appointed, by the Minister of Public Instruction, Lecturer on Electrical Engineering at the Sydney Technical College. Upwards of 60 students had entered for the course when the first lecture was delivered six weeks ago.

The Canadian Telegraphs.—Mr. F. N. Gisborne, Superintendent of the Government Telegraphs, has drawn up an elaborate report on the subject of the Canadian Government taking over the telegraphs of the Dominion. It will be presented to Parliament during the present Session.

The Chatham Accident.—In answer to a question asked in the House of Commons last week, the President of the Board of Trade stated that in consequence of the recent fatal accident the Chatham and Rochester and District Electric Lighting Company had been requested to make certain alterations.

The Paris-Brussels Telephone Line.—A further reduction is to be made in the telephone tariff between Paris and Brussels. A convention has been concluded between the French and Belgian Governments whereby the rate will be shortly reduced from 2s. 6d. for five minutes to 1s. 3d. for the same space of time. A third wire is on the eve of completion.

Taunton.—The Joint Committee of the Town Council, who have had the matter of the purchase of the electric light works

Digitized by Google

under consideration, have issued an elaborate report. The capital of the Company is £20,000, and the Borough Surveyor considers the purchase money should be about £10,000. At a noisy meeting of the ratepayers, held on Monday, a resolution adverse to the purchase was carried.

The Electric Light in Night Manœuvres.—On Saturday last the London Rifle Brigade executed some night manœuvres at Elstree, with a view of testing the utility of the electric light. The portable military search-light was placed on the rising ground on which the village of Elstree stands. From this position it completely commanded the surrounding country. The attacking force was shown up at long ranges, and kept well exposed throughout the operations.

Lord Kelvin.—"We do not think it indiscreet," says *La Lumière Electrique*, "to inform our readers that there is much talk at the Académie des Sciences of nominating Lord Kelvin as successor to the late Emperor of Brazil as one of the eight foreign associates. . . . It would certainly seem desirable that the Académie des Sciences should take this opportunity of adding an honour to that which the English Government has just rendered to the illustrious electrician which the Royal Society of London has honoured with its presidency."

Breslau.—The first six months' work at the central station erected by Messrs. Siemens and Halske in Breslau shows gross receipts amounting to £7,500; the expenditure, including the writing off of a proportion of the capital outlay, being about £6,300. At present 14,000 lamps are at work. The battery of 420 Tudor cells seems to give great satisfaction. As a rule the machines are run only from 5:30 to 10 o'clock daily, and on Sundays only for three and a-half hours. During the summer months it will only be necessary to run every other day.

Royal Institution.—The following are some of the lecture arrangements after Easter:—Mr. Frederick E. Ives, two lectures on Photography in the Colours of Nature; Prof. Dewar, four lectures on the Chemistry of Gases. The Friday evening meetings will be resumed on April 29th, when a discourse will be given by Dr. William Huggins on the New Star in Auriga; succeeding discourses will probably be given by Captain Abney, Dr. B. W. Richardson, Mr. J. Wilson Swan, Sir James Crichton-Browne, Mr. Ludwig Mond, Prof. Dewar, and others.

Cable Extensions.—The Eastern Extension Company have recently laid a cable (161 knots in length) between Penang and Sumatra, and have since entered into a contract with the Dutch Government to connect Olehleh (Acheen) and Laboean Deli (291 knots). This cable is being manufactured, and will be sent out about the end of April. These connections will give a triplicate route between Penang and Singapore and Penang and Banjoewangie (Java), and thus bring the important tobacco-growing districts into telegraphic communication with the rest of the world.

Simultaneous Telegraphy and Telephony.—The Picard system of simultaneous telegraphy and telephony (see *The Electrician*, Vol. XXVII., p. 560), together with the Van Rysselberghe and other similar systems, are to be experimentally tested by Mr. Preece next month over the London-Paris lines. Preliminary comparative trials are now being made between Paris and Nantes. As we stated some little time ago, the Picard system is in operation between Paris and Troyes and between Bordeaux and Arcachon. Van Rysselberghe's system is also used on several French lines.

The Paris Telephone System.—A Bill is now before the Chamber of Deputies asking for a vote of £160,000 for the purpose of reorganising the Paris telephone network, for which object a total of £320,000 will ultimately be required. The twelve existing exchanges are to be replaced by four large ones, situated in the Rue Gutemberg, Avenue de Wagram, Place de la République, and Avenue des Gobelins. Between September 1, 1889, and January 1, 1892, the telephone subscribers have augmented by 3,475, increasing the annual receipts by over £40,000.

The Electric Railway Schemes.—In the House of Commons on Monday, Mr. Whitmore moved—"That the resolution of the House of March 1st, relative to Electric and Cable Railways (Metropolis)., which was ordered to be communicated to the Lords, and the message from the Lords of March 7th, signifying their concurrence in the said resolution, be read; that the said Select Committee appointed to join with the Committee of the Lords do consist of five members, to be nominated by the Committee of Selection; that a message be sent to the Lords requesting their Lordships to appoint an equal number of Lords to be joined with the members of this House." The motion was agreed to.

Southport.—At a recent special meeting of the Town Council, convened to consider the supply of electricity for lighting by the Corporation, it was unanimously resolved—(1) That the installation be fixed at or near the gas works, and worked on the high-tension alternating-current system; (2) that plans for the buildings and plant be prepared as soon as possible; (3) that Mr. G. Wilkinson, of London, be appointed the engineer, his inclusive remuneration to be at the rate of 3 per cent. on the outlay. All questions of cost, street lighting, the the extension of the scheduled area, and the price to be charged (which, however, must not exceed 8d. per unit), were left for future consideration.

Bristol.—The buildings at the Temple Back station—like the foundations—are to be of a more extensive and substantial character than was at first contemplated; but it is hoped that the original estimate of £60,000 will not be exceeded. It has been decided to advertise for tenders for the erection of the station and stack, and also for boilers, engines, dynamos, and everything necessary for the station. The Electric Lighting Committee have determined to buy Lancashire boilers and Willans engines. A pamphlet is to be prepared setting forth the relative cost of electricity and gas. The plans for the central station have been prepared by Mr. Henry Williams, architect to the committee, and they provide for a substantial building of about 140ft. long, with an average depth of 100ft.

American Institute of Electrical Engineers.—In view of the projected International Conferences at the Chicago Exhibition, this Institute, which has done excellent work, has issued a pamphlet, briefly sketching its past history. Since its foundation, in 1884, the Institute has been the medium for the publication of a large number of useful and highly practical Papers, many of which have been reproduced in our columns. Amongst these we may cite that of Mr. A. E. Kennelly, on "Inductance and its proposed Unit the Henry;" Prof. Ryan's, on "The Effect of the Air Gap in Dynamos;" Mr. Tesla's, on "High Frequency Currents;" and many others of equal worth. It is hoped that the attention drawn to the work of the Institute, which now numbers some 600 members, will induce electrical engineers who purpose visiting Chicago next year to bring themselves into closer touch with American ideas by joining its ranks.

Cambridge.—A special meeting of the Town Council was held at the Guildhall on Thursday last week. The Electric Lighting Committee reported that Messrs. Parsons and Co. had offered to undertake to commence the electric light within the area of supply not later than the commencement of the next October term, and to proceed continuously with all possible despatch. The system employed would be the alternating-current system. The charge per unit should not in any case exceed 7d., and the Company would pay £1,000 towards the expenses of the Corporation, who should have the power to acquire the undertaking at the end of 21 years, upon paying for the undertaking as a going concern. The Committee considered the terms to be fair and reasonable, and recommended the Council to adopt them, and to instruct the Town Clerk to prepare an agreement in accordance with the provisions contained in the Provisional Order relative to the transfer of the powers of the Corporation under the Order. This report was unanimously agreed to.

Glasgow.—The Corporation having purchased a piece of ground 91 × 89ft. at the corner of Waterloo-street and Main-street for the purpose of erecting a central generating station, the contracts for the necessary buildings have been let, and

Digitized by Google

the work of erecting them is proceeding. It is intended in the first instance to put down plant capable of supplying 12,000 8 c.p. lamps. The station, however, will be sufficiently large to contain plant for the supply of 40,000 lamps. The chief building will be three stories in height. At the beginning there will be five steel boilers of the marine type, 10ft. in diameter and 12ft. in length, having a working pressure of 160lb. The engines will be Willans'. Of these there will be seven —two of 80 H.P., two of 150 H.P., and three of 250 H.P. Two of the seven dynamos will have an output of 400 amperes at 120 volts, two an output of 400 amperes at 230 volts, and three an output of 670 amperes at 230 volts. The current is to be distributed by means of copper strips placed in cast-iron troughs. It is anticipated that the station will be open by the end of August, and that some of the chief streets of the city will then be lighted with arc lamps. A sum of £8,000 has been paid for the ground. The erection of the buildings will absorb a sum of from £10,000 to £12,000, while a further sum of from £40,000 to £50,000 will be required for machinery and conductors, bringing up the total expenditure to between £60,000 and £70,000.

Large Glass Cells.—Hitherto glass cells have been blown, and owing to this their size has been very limited, the largest being only about 22in. long by about 12in. or 14in. deep, and the same in width. By the process now successfully carried out by Armstrong's Glass Company, of Birmingham, tanks and cells of any dimensions can be constructed. The process consists in welding or fusing plates or sheets of glass together, thus forming a solid glass tank, with all the advantages of having the sides straight, the bottoms level, and the angles all square and to accurate measurements, the blown boxes being frequently quite the reverse in these respects. Armstrong's Company show at the Crystal Palace one tank 4ft. 6in. long, made by their new process, which is briefly as follows:— A mould of iron of the interior dimensions of the tank is placed into a furnace, and upon this mould are fastened the plates of glass. The furnace is gradually heated until red hot. Then an oxyhydrogen blow-pipe, or an electric arc burner, is introduced to heat the edges. A small roller which is attached to the blow-pipe is next brought over the junction, and the joint formed. When all the joints have been finished the cell is left to anneal, and when perfectly cold the glass box or tank, thus formed out of five glass plates welded together, is lifted off the iron mould, being a perfect tank, solid throughout, and capable of resisting acids and alkalies. The same Company show an underground conduit for electric cables, formed of slabs of glass, grooved with longitudinal parallel grooves. In laying these, after the trench in the ground has been formed, a cement concrete trough is made; inside this trough a layer of pitch or asphalte is run in. Upon this soft pitch the bottom sections of the glass slabs are placed. Upon these the upper section of the glass slabs are placed, the joints being broken by each section. The whole is then run in with pitch or asphalte, and covered up with the concrete.

The London County Council Subways Bill.—On Tuesday this Bill came before the Select Committee of the House of Commons, presided over by Mr. H. Gladstone; Mr. Cripps appeared for the Electric Lighting Companies and the Telephone Companies. The Bill proposes that the County Council should have the power to extend the system of enclosing underground wires and pipes in an easily accessible subway instead of burying them in the earth, so as to mitigate the expense and annoyance caused to the public by the frequent cutting up of the streets. There are now nine streets in which these subways already exist, Garrick-street, Southwark-street, Commercial-road, Queen Victoria-street, the Victoria Embankment, Northumberland-avenue, Shaftesbury-avenue, Charing Cross-road, and Rosebery-avenue, comprising altogether 7,810 yards of subway, and these existing subways are under the control of the London County Council. Mr. Littler, in opening the case for the promoters, mentioned as an instance of the annoyance that was caused by there being so many bodies with powers to cut up the streets, that when the West Strand was repaved, no sooner had it been done than the water company came along and took up the whole of one side of it, and after they had done with it the gas company took up the other side. The subways had cost several thousand pounds a mile, and he thought it reasonable that something in the shape of rent should be paid for the use of them. The first witness called was Mr. A. Binnie, engineer-in-chief to the London County Council, who said there were in their subways 15,043 yards of gas pipes, 7,614 yards of hydraulic pipes, 6,492 yards of water pipes, 15,770 yards of telegraph and telephone wires, and 7,117 yards of electric wires. On Wednesday Mr. Cripps, Q.C., cross-examined on behalf of the Electric Lighting Companies, mentioned that the electric companies were not satisfied. Professor Forbes, who had been consulted in respect of the proposals of the Bill, testified that it would be to the public benefit to have the electric wires in the metropolis placed in the subways, that it would be a great advantage and saving to the electric companies, and that there would be no danger through the juxtaposition of the wires with various pipes. The Committee adjourned until Monday, in the hope that in the interval the differences between the opposing companies and the County Council would be cleared away altogether.

The Cost of the Electric Light in Mills.—The following facts relating to the electric lighting of some large steam mills at Barrow-in-Furness, belonging to Messrs. Walmesley and Smith, are from the *Engineer*. The installation, which was laid down in 1885, includes a Mather-Platt dynamo, driven through countershafting by a horizontal steam-jacketed Marshall engine, supplied with steam at 65lb. pressure from the mill boilers. The dynamo runs at 1,115 revolutions, the engine at 120 revolutions. Some 150 100-volt 16 c.p. Edison-Swan lamps were installed. The dynamo was started on March 6, 1885. The total outlay was £420. 10s. 11d.

General Working Expenses, Maintenance and Renewals.

—	1885-6.	1890-1.
	£ s. d.	£ s. d.
Interest (5 per cent.)	20 0 0	15 9 3
Depreciation	20 0 0	15 9 3
Fuel consumed (calculated at 3½lb. per I.H.P.H.)	22 5 6	47 17 6
Lamp renewals	22 5 0	9 10 9
Brush renewals	6 14 0	0 18 0
Commutator renewals	8 10 0	—
Fixing commutator and repairing ditto	4 8 7	0 10 0
Sundries and renewals	0 19 0	—
	105 2 1	84 14 9

Details of Lamp Hours and Lamp Hour Cost.

Number of hours run	3,163	3,477
Average number of lamps lit	100	127
Number of lamp hours	316,300	441·579
Cost per lamp hour	·079d.	·048
Number of lamps lit—one hour for 1d.	12·6	20·8

Renewals and Repairs.

Number of lamps renewed	95	59
Number of times commutator turned	8	2
Number of brushes used	8	1

Taking the average for the six years we have—Annual cost, £91. 19s. 11d.; cost per lamp hour, ·059d.; hours run, 3,392; lamps lit, 112·1; lamp hours, 380,243. The cost of gas in Barrow = 3s. per 1,000 cubic feet, so that the cost of an equal number of No. 5 burners, consuming 5½ cubic feet per hour at 3s. = £313. 13s. The 16 c.p. 100-volt lamp hour at ·059d. is equivalent to the Board of Trade unit at about ¾d. The average life of each lamp comes out at 3,384 hours, and there are two or three of the original lamps still burning, having run over 20,000 hours. The figures supplied with regard to the commutators are instructive: the first lasted 8½ months, the second 12, the third 24½, the fourth 14½; the fifth commutator, still in use, has run 3,500 hours, and has been turned up twice.

ELECTROMAGNETIC THEORY.—XXVI.

BY OLIVER HEAVISIDE.

(Continued from page 453.)

§ 126. The simplest and most easily understood effect of ∇ upon a function is when it acts upon a scalar, say P. This implies that P is a scalar function of position, or of x, y, z. In the most important applications P is single-valued, as when it represents density, or pressure, or temperature, or electric potential, or the corresponding magnetic potential of magnets. But P may also be multiplex, as when it is the magnetic potential outside a linear electric current. At present let P be simplex.

By (119) we have

$$\nabla P = \mathbf{i}.\nabla_1 P + \mathbf{j}.\nabla_2 P + \mathbf{k}.\nabla_3 P. \quad . \quad . \quad . \quad (137)$$

Of course, since ∇ is vector and P scalar, the result is a vector. Its meaning is easily found. From the fact indicated in (137) that the rectangular scalar components of ∇P are the rates of increase of P along the axes of **i**, **j**, **k**, we may conclude that the component of ∇P in any direction is the rate of increase of P in that direction. Thus, **N** being any unit vector, we have, by (137),

$$\mathbf{N}\nabla P = N_1\nabla_1 P + N_2\nabla_2 P + N_3\nabla_3 P. \quad . \quad (138)$$

Comparing with (121), we see that

$$\mathbf{N}\nabla P = (\mathbf{N}\nabla)P = dP/ds, \quad . \quad . \quad . \quad (139)$$

by (123), s being length measured along **N**.

The identity of $\mathbf{N}\nabla P$ and $\mathbf{N}\nabla$. P is tolerably obvious algebraically. It is not, however, true when for P is substituted a vector, as we shall see later.

If we take P = constant, we obtain the equation to a surface. If, then, **T** is any tangent to the surface at a chosen point, that is, any line in the tangent plane perpendicular to the normal, we shall have $\mathbf{T}\nabla P = 0$. The direction of ∇P itself is therefore that of the normal to the surface; or the lines of ∇P cut the equipotential surfaces perpendicularly, and pass from one to the next (infinitely close) by the shortest paths. The distance between any two consecutive equipotential surfaces of a series having a common difference of potential varies inversely as the magnitude of ∇P, and ∇P itself is the vector showing at once the direction and the rate of the fastest increase of P. No perfectly satisfactory name has been found for this slope, or space-variation of a scalar function. Comparing P with height above the level on a hillside, ∇P shows the greatest slope upwards. But the illustration is inadequate, since on the hillside we are confined to a surface.

The tensor of ∇P is given by

$$(\nabla P)^2 = (\nabla_1 P)^2 + (\nabla_2 P)^2 + (\nabla_3 P)^2, \quad . \quad (140)$$

as with any other vector.

We may also here notice the vector product $V\mathbf{N}\nabla$ in its effect on a scalar. We have, by the semi-Cartesian formula for a vector product,

$$V\mathbf{N}\nabla = \mathbf{i}(N_2\nabla_3 - N_3\nabla_2) + \mathbf{j}(N_3\nabla_1 - N_1\nabla_3) + \mathbf{k}(N_1\nabla_2 - N_2\nabla_1). \quad (141)$$

Thus, when the operand is scalar, as P, we shall have

$$(V\mathbf{N}\nabla)P = V\mathbf{N}\nabla P. \quad . \quad . \quad . \quad . \quad . \quad (142)$$

The result is a vector perpendicular to the plane of **N** and ∇P, as in any other vector product, vanishing when they are parallel, and a maximum when they are perpendicular.

§ 127. When the operand of ∇ is a vector, say **D**, we have both the scalar product and the vector product to consider. Taking the former alone first, we have

$$\text{div}\,\mathbf{D} = \nabla\mathbf{D} = \nabla_1\mathbf{D}_1 + \nabla_2\mathbf{D}_2 + \nabla_3\mathbf{D}_3. \quad . \quad . \quad (143)$$

This function of **D** is called its divergence, and is a very important function in physical mathematics. Its general signification will be best appreciated by a consideration of the Theorem of Divergence.

Let liquid be in motion. The continuity of existence of the matter imposes certain restrictions on the motion. The current is $m\mathbf{q}$ per unit area, where m is the density and **q** the velocity. But, to further simplify, let $m = 1$, making the liquid incompressible. Then the current is simply **q**, which measures the amount of liquid crossing unit area of any surface perpendicular to **q**. But if the surface be not perpendicular to **q**, the effective flux is only **Nq**, the normal component of **q**, if **N** denotes the unit normal to the surface. Therefore, $\Sigma\mathbf{Nq}$, or the summation of **Nq** over any surface, expresses the total flux of liquid through the surface.

Now suppose the surface (fixed in space) is closed. Then the summation represents the amount of liquid leaving the enclosed region per second through its boundary, if **N** be the outward normal. This amount is evidently zero, because of the assumed incompressibility. If then we observe, or state, that $\Sigma\mathbf{Nq}$ is not zero, either the fluid is compressible, or else there must be sources of liquid within the region. Adopting the latter idea, because it simplifies the reasoning, we see that the summation $\Sigma\mathbf{Nq}$ is the appropriate measure of the total strength of the sources in the region, since it is the rate at which liquid is being generated therein, or the rate of supply. The position of the internal sources is quite immaterial, and so is the shape of the region, and its size, or the manner in which a source sends out its liquid (*i.e.*, equably or not in all directions). So we have

$$\Sigma\mathbf{Nq} = \Sigma\rho, \quad . \quad . \quad . \quad . \quad . \quad . \quad (144)$$

if ρ represents the strength of a source, and the Σ includes them all.

When the sources are distributed continuously, so that ρ is a continuous function of position, its appropriate reckoning is per unit volume. That this is the divergence of **q** is clear enough, according to the explanations relating to divergence already given. That it is the same as $\nabla\mathbf{q}$, as in (143), we may prove at once by the Cartesian form there exhibited.

We have to reckon the flux outward through the sides of a unit cube. Take its edges parallel to **i**, **j**, **k** respectively. Then there are two sides whose outward normals are $-\mathbf{i}$ and **i**, and their distance apart is unity. The outward fluxes due to them are therefore $-\mathbf{iq}$, or $-q_1$, and $q_1 + \nabla_1 q_1$, whose sum is $\nabla_1 q_1$. Similarly the two sides whose normals are $\pm\mathbf{j}$ contribute $\nabla_2 q_2$, and the remaining sides contribute $\nabla_3 q_3$. Comparing with (143), we verify the Cartesian form of the divergence of a vector.

But we may have any number of other special forms, according to the co-ordinates we may choose to employ for calculating purposes, such as spherical, columnar, &c., and the most ready way to find the corresponding form is by the immediate application of the idea of divergence to the volume-element concerned. For purposes of reasoning, however, it is best to entirely eliminate the idea of co-ordinates. Divergence is independent of co-ordinates.

The sources need not be so distributed as to give rise to a finite volume-density. We may have, within the region concerned, surface-line or point-sources, and the principle concerned is the same throughout. Thus the density of a surface source is measured by the sum of the normal fluxes on its two sides per unit area, that is, by $\Sigma\mathbf{Nq}$ applied to the two sides of the unit area, if the flux wholly proceeds outwards. This is, however, not fully general, as there may be a flux in the surface itself, so that the full measure of the surface density has to include the divergence of the surface flux, to be found by calculating the flux leaving the unit area across its bounding line. Similar considerations apply to linear sources. In the case of a point-source the measure of the strength is the flux outward through a closed surface enclosing the point infinitely near it—the surface of the point, so to speak. Any other surface enclosing the point will do, provided there are no other sources brought in by the change. There may also be multiplex sources. Thus, a pair of equal point-sources, one a source, the other a sink, would be equivalent to no source at all if brought infinitely near one another; but if the reduction in distance be accompanied by a corresponding increase in strength of the sources, the final result is not zero. This is the case of a magnetised particle on the theory of magnetic matter; but it is not necessary or desirable to complicate matters by entering

Digitized by Google

upon special peculiarities of discontinuity in considering the Divergence Theorem. Its general form being

$$\Sigma \mathbf{ND} = \Sigma \operatorname{div} \mathbf{D}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (145)$$

when the vector **D**, to which it is applied, admits of finite differentiation, the special meanings to be attached to the divergence of **D**, in order to satisfy the principle concerned, may be understood.

Although a material analogy, as above, is very useful, it is not necessary. Any distributed vector magnitude will have the same peculiarities of divergence as the flux of a liquid. If it be the motion of a real expansible fluid that is in question, then the divergence of its velocity represents the rate of expansion. It would, however, be very inconvenient to have to carry out this analogy in electric or magnetic applications; an incompressible liquid, with sources and sinks to take the place of expansions and contractions, is far more manageable.

§ 128. The following way of viewing the Divergence Theorem, apart from material analogies, is important. Consider the summation $\Sigma \mathbf{ND}$ of the normal component of a vector **D** over any closed surface. Divide the region enclosed into two regions. Their bounding surfaces have a portion in common. If, then, we sum up the quantity **ND** for both regions (over their boundaries, of course), the result will be the original $\Sigma \mathbf{ND}$ for the complete region. The normal is always to be reckoned positive outwards from a region, so that on the surface common to the two smaller regions **N** is + for one and − for the other region, and $\Sigma \mathbf{ND}$ for one is the negative of that for the other, so far as the common surface goes.

Since this process of division may be carried on indefinitely, we see that the summation $\Sigma \mathbf{ND}$ for the boundary of any region equals the sum of the similar summations applied to the surfaces of all the elementary regions into which we may divide the original. That is,

$$\Sigma \mathbf{ND} = \Sigma \phi(\mathbf{D}), \quad . \quad . \quad . \quad . \quad . \quad (146)$$

where, on the right side, we have a volume-summation whose elementary part $\phi(\mathbf{D})$ is the same quantity $\Sigma \mathbf{ND}$ as before, belonging now, however, to the elementary volume in question. We have already identified $\phi(\mathbf{D})$ with the divergence of **D**.

But if this demonstration be examined, it will be seen that the validity of the process whereby we pass from a surface to a volume summation, depends solely upon the quantity summed up, viz., **ND**, changing its sign with **N**. We may therefore at once give to the Divergence Theorem a wide extension, making it, instead of (146), take this form:—

$$\Sigma \mathrm{F}(\mathbf{N}) = \Sigma f(\mathbf{N}). \quad . \quad . \quad . \quad . \quad (147)$$

Here, on the left side, we have a surface, and on the right side a volume summation. The function $\mathrm{F}(\mathbf{N})$, where **N** is the outward normal, is any function which changes sign with **N**. The other function $f(\mathbf{N})$, the element of the volume summation, is the value of $\Sigma \mathrm{F}(\mathbf{N})$ for the surface of the element of volume. Thus, by considering a cubical element,

$$f(\mathbf{N}) = \nabla_1 \mathrm{F}(\mathbf{i}) + \nabla_2 \mathrm{F}(\mathbf{j}) + \nabla_3 \mathrm{F}(\mathbf{k}) \quad . \quad . \quad (148)$$

is the Cartesian form, should $\mathrm{F}(\mathbf{N})$ be a scalar function, or the semi-Cartesian form should it be a vector function. A few examples of the general theorem (147) will be given later. In the meantime the other effect of ∇ should be considered.

§ 129. The vector product of ∇ and a real vector, say **E**, is given in semi-Cartesian form by

$$\begin{aligned} V\nabla\mathbf{E} &= \mathbf{i}(\nabla_2 \mathrm{E}_3 - \nabla_3 \mathrm{E}_2) + \mathbf{j}(\nabla_3 \mathrm{E}_1 - \nabla_1 \mathrm{E}_3) + \mathbf{k}(\nabla_1 \mathrm{E}_2 - \nabla_2 \mathrm{E}_1) \\ &= \operatorname{curl} \mathbf{E}. \quad . \quad . \quad . \quad . \quad . \quad (149) \end{aligned}$$

As before, with respect to the divergence of a vector, we can best appreciate the significance of this formula by the general property involved, expressed by the Theorem of Version.

On any surface draw a closed curve or circuit. Let, for distinctness, **E** be electric force. Calculate the voltage in the circuit due to **E**. The effective force per unit length of circuit is the tangential component of **E**, or **TE**, if **T** is the unit tangent. The voltage in the circuit is, therefore, $\Sigma \mathbf{TE}$, the summation being circuital, or a line-integration extended once round (along) the closed curve.

Now draw on the surface a line joining any two points of the circuit. Two circuits are thus made, having a portion in common. Reckon up the voltage in each of the smaller circuits and add them together. The result is the voltage in the first circuit, if we rotate the same way in both the smaller circuits as in the original, because the common portion contributes voltage equally and oppositely to the two smaller circuits.

This process may be carried on to any extent by drawing fresh lines on the surface. We therefore have the result that the voltage in the circuit bounding a surface equals the sum of the voltages in the elementary circuits bounding the elements of surface. Or

$$\Sigma \mathbf{TE} = \Sigma \theta(\mathbf{E}), \quad . \quad . \quad . \quad . \quad . \quad (150)$$

where on the left side we have a circuital summation, and on the right side an equivalent surface summation, in which $\theta(\mathbf{E})$, the quantity summed, is the value of $\Sigma \mathbf{TE}$, that is, the voltage in the circuit bounding the particular element of surface concerned.

To find the form of θ in terms of **i**, **j**, **k**, &c., we need only calculate the voltages in unit square elements of surface taken successively with edges parallel to **j**, **k**, to **k**, **i**, and to **i**, **j**. In the first case, when the normal to the square circuit, or the axis of the circuit, is **i**, the voltage is

$$\nabla_2 \mathrm{E}_3 - \nabla_3 \mathrm{E}_2,$$

that is, by (149), the **i** component of $V\nabla\mathbf{E}$, and therefore the normal component, since here $\mathbf{N} = \mathbf{i}$. Similarly when $\mathbf{N} = \mathbf{j}$, and the axis of the circuit is **j**, the voltage in it is expressed by the coefficient of **j** in (149). And when $\mathbf{N} = \mathbf{k}$, the voltage is the coefficient of **k** in (149). Thus, in any case, the voltage in an elementary circuit of unit area is the normal component of $V\nabla\mathbf{E}$, that is, $\mathbf{N}V\nabla\mathbf{E}$. So (150) becomes

$$\Sigma \mathbf{TE} = \Sigma \mathbf{N}V\nabla\mathbf{E} = \Sigma \mathbf{N} \operatorname{curl} \mathbf{E}, \quad . \quad . \quad (151)$$

expressing the Theorem of Version, sometimes termed Stoke's Theorem.

When **E** is not electric force, $\Sigma \mathbf{TE}$ is not circuital voltage, but circuital something else; but this does not affect the general application of the theorem.

This theorem is particularly important in electromagnetism because it is involved in the two fundamental laws thereof, what were termed the First and Second Circuital Laws, or Laws of Circuitation, connecting together the electric and magnetic forces and their time variations. (*See* §§ 33 to 36, Chap. II., and later.)

If the vector whose curl is taken be velocity **q** in a moving fluid, then curl **q** represents twice the spin or vector angular velocity of the fluid immediately surrounding the point in question; its direction being that of the axis of rotation, and magnitude twice the rate of rotation. But I have not made use of the fluid analogy in describing and proving the Version Theorem, because it is not of material assistance.

Since the validity of the process whereby we pass from a circuital summation of the tangential component of a vector to an equivalent surface summation depends upon the fact that **TE** changes sign with **T**, we may generalise the theorem thus:—

$$\Sigma \mathrm{F}(\mathbf{T}) = \Sigma f(\mathbf{T}), \quad . \quad . \quad . \quad . \quad . \quad (152)$$

where on the left we have a circuital and on the right a surface summation, and $\mathrm{F}(\mathbf{T})$ is such a function of **T** as to change sign with **T**; whilst $f(\mathbf{T})$, the element of the surface summation, is the value of the former $\Sigma \mathrm{F}(\mathbf{T})$ for the particular element of surface in question. Of this general theorem a few examples will be given later.

A few words regarding ∇, div and curl, terminologically considered, may be useful. Since divergence and curl are expressible in terms of vex (a provisional name for ∇, which has been suggested to me), why not use the vex operator only, like the quaternionists? The reasons, which are weighty, should be obvious.

In the first place, we require a convenient language for describing or referring to processes and results, expressing approximately their essential meaning without being too mathematical. Now ∇ alone is not convenient for this purpose. The scalar product of ∇ and **D** conveys no such distinct idea, as does

Digitized by Google

divergence; nor does the vector product of ∇ and **E** speak so plainly as the curl or rotation of **E**.

Besides, the three results of ∇, exemplified in ∇P, and ∇**D**, and ∇ ∇ **E**, are so remarkably different in their algebraical development and in their meaning, that it is desirable, even in the algebra, to very distinctly separate them in representation. Therefore, in the preceding part of the present work (as in all former papers), the symbol ∇ is only prefixed to a scalar, as in ∇P, the space variation of P, whilst for the scalar and vector product are employed div and curl, in the formulæ as well as in descriptive matter.

There are, however, cases when it may be desirable to use ∇ and V∇ applied to vectors in formulæ, namely, when the combinations of symbols are not so simple that their meaning and effect can be readily seen, and when it is required to perform transformations also not readily recognisable. The utility of ∇ in its vectorial significance then becomes apparent, for one may use it alone, temporarily if desired, and work it as a vector, remembering, however, its other functions. Of this, too, some examples should be given.

(To be continued.)

FERRANTI ELECTRICITY METERS.

Mr. Ferranti has devoted considerable attention to electricity meters ever since their first inception. Patents have been taken out by him embodying alternating or continuous current meters, meters having shunt compensating circuits, and "double sealing," *i.e.*, a fastening for the part to be certificated, and a fastening to protect against interference with the connections, since rendered essential by the regulations of the Board of Trade, &c., and with which all Ferranti meters are provided. The Ferranti meters are substantially constructed, and, while being accurate recorders, they are designed so as to be suitable for the position and usage to which appliances of this kind must necessarily be more or less subject. Completely enclosed in metal cases they are both air and watertight.

Continuous-Current Meter.—The essential principle of the Ferranti continuous-current meter (Fig. 1) is, as is well known, the measurement of the rotation of a bath of mercury through which the current passes from the periphery to the centre after energising a magnetic field; the lines of force being at right angles to the radial direction of the current in the mercury. The speed of rotation increases in direct proportion to the current, and the movement is transmitted to the register by a fan which is mounted on a light spindle and immersed in the bath. The registering of the meter is as simple as the mechanism. The face is marked with six dials, units, tens, hundreds, &c., and the amount registered on these, when divided by the constant stated in the instructions issued with the meter, gives the number of Board of Trade units consumed. A feature of the Ferranti meter is the extremely small amount of energy required to work it, and the consequent absence of any observable drop in pressure due to resistance or work being put in series with the lamps. There is only one moving part, and this is perfectly enclosed in a metal case, entirely inaccessible, and is unaffected by external influences. The correctness of its record would not be impaired by a magnet being placed near it, as might be done by a dishonest consumer. It is, indeed, a motor meter of the simplest form, and as such does not require to be touched for winding up or recalibration. It is made entirely of uninflammable material, can be quickly installed and connected, and is suitably designed to prevent it being tampered with afterwards.

The Ferranti meter will, at its best, start registering at ·4 per cent. of its limiting load, and will register with less than 3 per cent. error over 95 per cent. of its working range. For instance, a 100-ampere meter will start registering at ·35 ampere, and will register correctly from less than five to 100 amperes.

Size.	Maximum Revs. per Minute	Starting Current.
100-ampere meter	275	0·35
50-ampere meter	250	
25-ampere meter	275	
10-ampere meter	220	

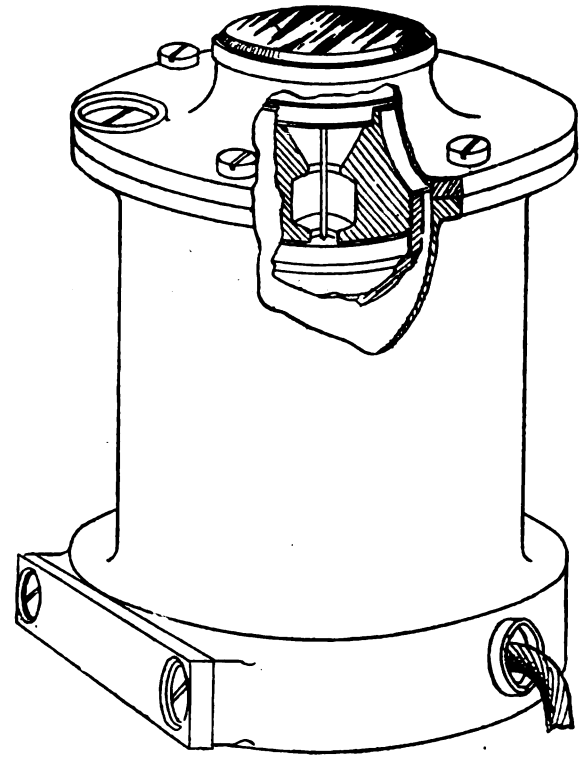

Fig. 1.—Ferranti Electricity Meter for Continuous Currents.

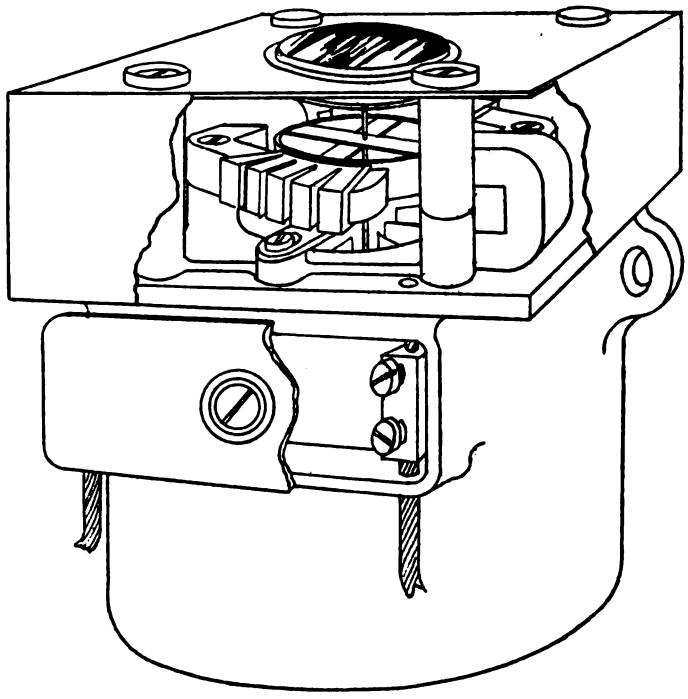

Fig. 2.—Ferranti Electricity Meter for Alternate Currents.

Alternate-Current Meter.—The alternate-current meter designed by Mr. Ferranti in conjunction with Mr. Arthur Wright consists essentially of a small non-synchronous motor, having a rotary field, through the magnet windings of which the current flows. The armature (Fig. 2) is a small metal disc, revolves at a speed proportionate to the current, and is geared directly to the counting train. The meter is enclosed

Digitized by Google

in a metal case, and embodies the double sealing to which reference has already been made. A diagrammatic view of the internal arrangements of this meter as seen from above is given in Fig. 3. The pole pieces of the magnet, it will be observed, are

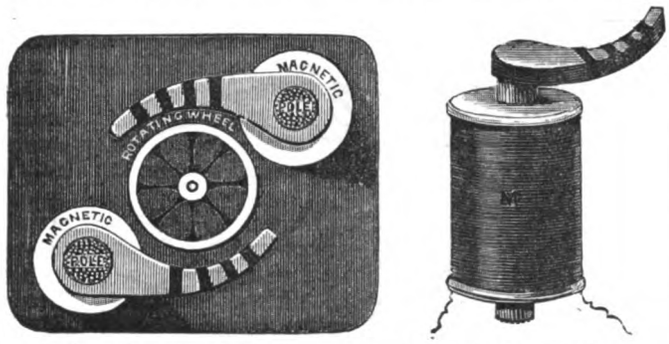

FIG. 3.—Diagrammatic View of Ferranti Alternate-Current Meter.

curved, the iron being divided in a horizontal plane. These horn-like protuberances, which are "magnetically" throttled at intervals by encircling copper bands, embrace the revolving metal disc forming the armature of the meter. The *modus operandi* of the apparatus is somewhat as follows:—The throttling of the curved iron horns causes the lines of force to issue from the circuit in a series of "puffs," setting out laterally from the sides of the horn, and travelling up it. The passage of these lines through the rim of the revolving wheel generates eddy currents in it, which are continually repelled by the field moving along the pole-piece.

The particulars given below are of unshunted meters.

Size.	Maximum revs. per minute.	Maximum watts consumed.	Starting current.
80 amperes	450	9·0	2·0 to 2·5
60 ,,	450	9·0	1·5 to 1·8
40 ,,	450	9·0	1·0 to 1·2
20 ,,	450	9·0	0·5 to 0·6
10 ,,	416	9·0	0·3 to 0·4

THE LONDON CHAMBER OF COMMERCE AND THE TELEPHONE SERVICE.

A deputation waited on the Postmaster-General on Monday afternoon from the London Chamber of Commerce, for the purpose of laying before him the views of the commercial community with regard to the telephone system of the country.

Sir ALBERT ROLLIT, M.P., in introducing the deputation, said that it was representative of the commercial feeling, not only of London, but, as he believed, also of the country. The reason they had come to the Postmaster-General was because the London Chamber of Commerce had, for a long time past, taken a very great interest in the subject of telephonic communication—so much interest that it had in connection with it an association for the purpose of watching the development of matters, and doing its best to improve and promote communication by means of the telephone and otherwise. The ground upon which they came was entirely a public one. The object of the Chamber had been and was to procure the best and cheapest mode of telephonic communication. The Chamber knew perfectly well, from its familiarity with business, that nowadays despatch was an essential element of profit, and that unless communication were good it was not possible to compete with other nations in relation to cost of production and the like. The opinion of the Chamber was that every possible facility should be given in our own country for similar commercial advantages. With the object of testing public feeling on the subject a conference was recently held at the Chamber, when he had the honour of being in the chair, and when a very impartial, and certainly a very prolonged, hearing was given to the views of all parties who were interested in that most important subject. The telephonic companies, both the existing one and the proposed new one, were represented, and equally the commercial public was largely present. What passed at that meeting was briefly this: that those who represented commerce complained in strong terms that the existing facilities were neither so great nor so cheap as the existing state of commerce demanded. On the other hand, the telephonic companies urged that they were in want of those powers the possession of which was essential to the proper performance of the duties entrusted to them. The deputation did not on this occasion propose to enter upon the discussion of that question. The feeling of the meeting was, he thought, distinctly that powers were claimed on behalf of the companies which were of a large character, and which, if granted, would lead to a great amount of private and public inconvenience. In that respect the existing company claimed rights which would give them the privilege of going upon private property, and, in a measure, of interfering with the use of it under statutory powers. Equally public authorities who at present possessed rights in relation to the user of the roadways, and so on, would have those rights infringed upon because the roadway could be taken, and overhead wires in almost an unlimited quantity, and very often at by no means proper heights, could be placed. There was no security given for the greater use of what he thought was so very essential, namely, underground wires, and he noticed that even estuaries were proposed to be invaded under the Bills which were before Parliament. That meeting having patiently heard all that was to be said on the question, came ultimately to this resolution, which he put before the Postmaster-General as expressing the considered views of the London Chamber of Commerce:—"That in view of the importance of the telephone industry, and the fact that two separate Companies have Bills before Parliament, this Chamber should appoint a deputation to apply for an interview with the Postmaster-General, and express the views of the Chamber as to the supreme importance of Her Majesty's Government bringing a General Powers Bill into Parliament, so as to confer facilities for the development of the telephone, not only in the metropolis, but also with regard to the inter-town services all over the country, whether by private companies or by the Government." The feeling of the Chamber and of the public, as far as he could judge, seemed to be that in the case of the Bills presented by each of those companies they were Bills distinctly of a private character. They created no obligation to confer telephonic facilities, they prescribed no limitation of the cost at which those facilities were to be given, they placed no limitation on the dividend which was to be paid; and, briefly, they scarcely so much contemplated public rights and advantages as private property to the companies themselves. On the other hand, they thought that if the Government brought in a Bill of the general character which had been indicated, and giving powers which undoubtedly were in some cases urgently required, but giving those powers subject to conditions which the Government might be able to prescribe in a Bill of that character, and enabling not only the Department which the Postmaster-General represented, but its licensees, to do those things which were absolutely necessary for telephonic development, subject to proper limitations for the protection of the public—they thought that a measure of that character was required for telephonic purposes, and would be of great public advantage. Viewing the matter in that light, with the object of serving the public and at the same time properly encouraging private enterprise, but encouraging the latter under proper limitations and restrictions, and giving a control power which those Bills did not certainly contain, they thought that that was the proper course to pursue, and that was a course which they came to strongly urge upon the Government. He had the honour to introduce the deputation, and to state that the resolution expressed the sentiments of the London Chamber of Commerce, and he asked the Government strongly to take the matter in hand in the public interest, and to introduce a General Powers Bill, which would do much to advance telephonic communication and competition under proper rights and restrictions. He would now ask Mr. Faithfull Begg, who was present at the meeting of the London Chamber of Commerce, and who took an interest in the subject, to add to the remarks which he had made.

Mr. FAITHFULL BEGG said the Chamber of Commerce had come to the conclusion that the telephone was a great public convenience and commercial facility, but that its development had not reached anything like the scope or extent in this country which might be realised under more favourable conditions. Looking at the history of the telephonic industry in Great Britain, he thought there were two chief reasons why it had not developed as it might have done. The first was undoubtedly the absence of statutory provisions or facilities whereby wires could be run independently of the caprice of individuals. It had frequently been the case that a city line—a line in a town like London—had had to be taken a very long distance out of the direct route merely because one particular attachment on an individual roof could not be obtained upon reasonable terms. The same applied to the trunk-wire communication in the country, where the local authorities had in many cases absolutely refused to consider any applications for the running of wires, no matter how urgent these might be; and consequently the routes had been blocked. The other reason which he thought had delayed the development of the industry had been, he said it with diffidence in the presence of Sir James, the restrictive policy of

Digitized by Google

the Department. The Department, of course, had a great public property to protect in the telegraph; and naturally in the early stages of the industry it was not easy to quite see what facilities ought to be given or withheld. But undoubtedly as time had gone on the Department, he thought, had not shown a sufficiently liberal spirit in dealing with the companies. He would point out that quite recently the Telephone Company in London offered to connect up all the post-offices with their system, so that the public might have the free use of it from all these various points. A more important direction in which the Department had exercised its power had been in connection with their right of way-leave over railways, where they had not allowed, so he understood, the companies to pass under any circumstances.

The POSTMASTER-GENERAL: That is a mistake, they allow them to pass on payment of rather a heavy way-leave.

Mr. FAITHFULL BEGG: At all events, proper facility has not been granted. What was wanted was not that any individual company should be favoured, but that some means should be found whereby to properly constituted companies necessary facility should be granted, either through the Department, or direct under a Bill similar to the Electric Lighting Bill, in order that the difficulties under which they laboured should be removed.

The POSTMASTER-GENERAL: Mr. Lamb informs me that the request referred to to connect with the post-offices has never been made since the late Postmaster-General, Mr. Fawcett, made the existing settlement with the companies.

Mr. Sheriff FOSTER, speaking on behalf of the subscribers of the Telephone Company in London, said the resolution of the Chamber, of course, went beyond London; but, after all, he thought London, with its very large needs, was, perhaps, at the present moment about as inefficiently served as any large town in the United Kingdom. The London consumer paid about the maximum price for about the minimum amount of efficiency. The charge in London at the present moment was twice as much, and even three times as much, as the charge in some of the other towns in the kingdom. They were told that this charge was to a large extent due to the difficulty of getting way-leaves at anything like a reasonable rate in London. Therefore, it appeared obvious that some statutory power ought to be conferred upon the authorities who had the power to lay the telephone wires to establish their way-leaves compulsorily, under, of course, proper provisions for compensation. Some power for dealing with the opening of the streets should, he thought, also be granted them. Whether the Department could not, perhaps, more easily deal with the question of the streets, and then, perhaps, place in the hands of the company, or competing companies, the power to supply the telephone, he would not venture to indicate.

Mr. W. C. JACKSON said he represented a powerful voluntary association, known as the Telephone Subscribers' Protection Association. That association sprang into existence in consequence of a meeting which was summoned nine months ago at a public hall in Cannon-street, at which no less than 400 dissatisfied telephone subscribers attended. That meeting was only summoned by public advertisement, and the attendance represented a very strong feeling on the part of the body of London subscribers. That association existed only for the purpose of benefiting the subscribers to telephones in London. It was not in antagonism to the existing system, except in so far as that was inefficient; it desired to show no favour to any other system than that which would give the best communication. Since their association had made itself felt there had been, he thought, considerable improvements in the telephonic system in London. There had most undoubtedly been much greater attention on the part of the *employés*. He would impress upon him the fact that Mr. Sheriff Foster, when he spoke individually, nevertheless spoke with the same voice as not less than 1,000 members who have banded themselves together for the sole purpose of benefiting their common interests. There were two classes of persons for whom he himself spoke, the persons in large business or practice, to whom £20 was a small item, but to whom celerity, clearness, and other things were a first essential; and the very considerable number of smaller persons to whom £20 a year was a very serious matter.

Mr. SYDNEY MORSE, on behalf of that section of the public which was represented by the electric lighting industry, said that section was a very large industry now. The Board of Trade had granted a great many orders, of which at the present time 160 were effective. With the exception of some 20 or 30 metropolitan orders, each of those orders represented a district as large as Leeds, or Manchester, or Liverpool, and so on throughout the country. The telephone companies said that they did them a great deal of harm, and were one of the causes of their service being inefficient. They, on the other hand, said that the telephone companies could carry on their business with much greater efficiency and without being damaged in any way by the electric light industry if they would carry it out in accordance with modern principles of telephonic communication. They simply asked that their interests should be considered. They fancied the telephone companies claimed an absolute right to earth for their business; but what the electric light companies said was that if the telephone business could be carried on as stated without being damaged, that improved system ought to be adopted by the telephone companies. They themselves were under statutory powers, those powers being in effect the right to break up streets, in return for which the Board of Trade had the right to lay down regulations to see that they carried on their business in a reasonable manner. They thought if the telephone companies claimed large rights they ought to be put under regulations which would protect everyone, and would not be detrimental to their system. He was simply asking that the existing interests under the Electric Lighting Acts should be taken into special account.

Sir ALBERT ROLLIT said that those were the speakers who desired to address the Postmaster-General. At the same time it was only right that he should say there were two bodies represented who had not had any spokesman that day, but who had abstained upon the condition that they should put the matter impartially before him. He desired to say that neither of them in relation either to their management or their Bills should be considered to be prejudiced. They were Col. Jackson and Mr. Gane as representing the National Telephone Company, and his Grace the Duke of Marlborough as Chairman of the New Company; and therefore the observations of the speakers, as far as they had regard to the Bills, must be taken as being put before the Postmaster-General not controversially, and not certainly as having been answered.

The POSTMASTER-GENERAL, in reply, after intimating his regret that his room afforded but inadequate accommodation for the large number of gentlemen composing the deputation, said: I suppose, in reference to the last remark that Sir Albert Rollit made, that the promoters of both the private Bills, both the National Company and the New Company, would say that they were in favour of your general object; for undoubtedly they must, even in their own interest, desire that the London telephonic facilities be increased, and that the restrictions which stand in the way of their extension by means of the companies should be removed. Ever since I came to the General Post Office, I have given anxious and particular attention to the subject which you have brought before me to-day; and I shall be prepared, when the private Bills promoted by the two companies or groups of companies come on for second reading to-morrow, to make a general statement as to the policy of the Government and the scheme which the Government has formed for the promotion of the objects which you have represented to-day. It would be impossible, and it would not be respectful to the House of Commons, to anticipate that statement; but I can assure you that the matter is one to which the Government have given much attention, and I would add that their objects will be promoted and supported by the interesting statements you have made to me just now. I think I could not add anything to that at the present time, but I am exceedingly glad that you have put your views before me.

Sir ALBERT ROLLIT, on behalf of the deputation, thanked Sir James Fergusson for having granted them the audience; and the deputation then withdrew.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, March 25th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1) "On the Electromotive Forces of Gold and Platinum Cells." By Prof. Herroun. (2) "On a New Instrument for showing the Effects of Persistance of Vision." By E. S. Bruce, M.A. (3) "Some Electrical Instruments." By R. W. Paul.

OLD STUDENTS' ASSOCIATION.

7.30 p.m. Smoking Concert at the Masons Hall Tavern.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Posy Rings." By Dr. John Evans, F.R.S.

TUESDAY, March 29th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "On Mean or Average Annual Rainfall, and the Fluctuations to which it is subject." By Alexander R. Binnie, M.Inst.C.E.

WEDNESDAY, March 30th.

CHEMICAL SOCIETY.

4 p.m. Annual Meeting. President's Address; Election of Office Bearers and Council.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Foreign Exchange." By Ewing Matheson.

FRIDAY, April 1st.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Smoking Concert at St. James's Hall Restaurant.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Motion of the Ether near the Earth." By Prof. Oliver Lodge, F.R.S.

STEEL-PLATE PORTRAITS

Of W. H. Preece, F.R.S.; Michael Faraday (out of print); Sir John Pender, K.C.M.G.; Sir William Thomson, F.R.S. (Past-President of the Institution of Electrical Engineers); C. H. B. Patey, C.B. (Late Secretary of Telegraphs, G.P.O.); Dr. John Hopkinson, F.R.S. (Past-President of the Institution of Electrical Engineers); Dr. Oliver J. Lodge, F.R.S., Prof. William Crookes, F.R.S. (Past-President of the Institution of Electrical Engineers); Willoughby Smith (out of print); Prof. von Helmholtz and Prof. W. E. Ayrton (President of the Institution of Electrical Engineers), have been issued as Supplements to "THE ELECTRICIAN."

A few Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, 4s. 6d, carriage paid (U.K.)

THE GOVERNMENT AND THE TELEPHONES.

On Monday, December 21, 1880, it was decided by Mr. Justice STEPHEN that telephones were telegraphs, and consequently the monopoly of the Post Office. By this fortunate legal decision a powerful Government department was given a splendid opportunity of rendering at the same time a great public service and clearing itself from the imputation that its vision was limited to the length of its nose. Had it risen for a moment above the narrowest revenue considerations, it might have seen in GRAHAM BELL's invention an instrument of great utility, destined, if energetically worked, to extensive use, and likely, therefore, to ultimately become a source of income. At least, the telephone might have been frankly accepted and countenanced. It was, however, decided to levy a tax of 10 per cent. upon the gross receipts of companies sufficiently enterprising to provide a town or district with a telephone service, and to discourage the too rapid growth of a dangerous competitor. But the telephone was not to be snuffed out; and, 10 per cent. tax and other departmental impediments notwithstanding, it has progressed, though at a rate considerably slower than in countries where a more public spirited policy has been pursued, until its insidious inroads into the telegraph revenue has necessitated a *volte face* on the part of the Post Office. In future, said the Postmaster-General in the House of Commons on Tuesday night, on rising

Digitized by Google

to oppose the second reading of the New Telephone Company's Bill, the greatest encouragement will be given to the development of the telephones, and the Post Office will work entirely in alliance with them. Why any other policy but this should have ever been adopted is now only a matter of interest to the student of history. We have it from the Postmaster-General himself that the cold-shoulder attitude has been a failure, in that it has not prevented the growth of the telegraph revenue being checked, although it has succeeded in getting things telephonic into such an inextricable tangle that in London, the largest and busiest city in the world, the telephone is not used one quarter as much as in Berlin, a capital but little more than one quarter its size.

Such has been the policy of the Post Office in the past, and such its result; what its exact future policy is to be we cannot tell until the Government Bill is introduced next week, but enough was said by Sir James Fergusson on Tuesday to leave little else than mere details to be supplied. At present the telephone companies are restricted from delivering messages, they are not allowed to place call boxes in post-offices, they cannot run their lines along railways, roads, and canals where the Post Office have entire concessions without paying heavy wayleaves, there is no connection between telephones and telegraphs, and no powers to run the wires either underground or overhead. In future there is to be no restriction on the delivery of messages, call-boxes are to be placed in post-offices wherever possible, the charges for wayleaves will be reduced to a nominal sum, we are to be permitted to telephone our telegrams to telegraph offices, moderate powers for running overhead wires will be conferred on the Post Office licensees, and the Post Office itself will undertake to run the inter-exchange wires underground.

All this, it is needless to say, is not going to be done merely out of an amiable desire to increase telephonic facilities, or to assist the National Company in its task of dividend earning. These concessions, we are told, if granted without corresponding provisions for the protection of the public revenue, would be very dangerous; for if the telephone companies were in communication with all the large towns, and sent messages all over the country, the system would to a large extent supersede the use of the telegraph, and consequently largely diminish the telegraph revenue. Rather than contemplate such a terrible contingency as that, the Government propose—to boldly take over the entire telephonic system of the United Kingdom, as they might have done last summer on favourable terms,—no, not at all; they propose to take possession of the trunk wires. On the face of it, there is, from the telegraph revenue point of view, a logical completeness about the idea which at once commends it. So far as inter-house telephony is concerned it has rather created a new habit than superseded an old one; and it may be doubted whether the growth of an exchange appreciably diminishes the rate of increase of the telegraph business in the town in which it is situated. Inter-urban telephony, on the other hand, is evidently destined to largely take the place of inter-urban telegraphy. It seems, therefore, but logical that the Post Office should seize the one and leave the other. Dual control, however, is not as a rule conducive to efficiency. It is to be hoped, moreover, that the Post Office intend to devote plenty of money to increasing the number of trunk wires. Something like half a million sterling has been expended within the past few years on our existing telephone trunk communications, and even with the comparatively high tariffs at present in vogue and other restrictions the lines are fully occupied. With tariffs reduced, restrictions removed, and the inter-urban lines converted into public telephonic highways, the copper that will be required will be something prodigious if the service is to be up to the high standard we are accustomed to expect from the Post Office electricians.

The outcry against the National Company has been loudest in London, and it is the Metropolis which will be but indirectly affected by the grand new Post Office scheme. London telephone subscribers complain of indifferent service and excessive charges, and would prefer a radical improvement in these matters to cheaper communication with Liverpool, and permission to telephone their telegrams whenever cross-talk and leakage currents permit of so delicate an operation. It is certainly true that the getting of wayleaves is to be facilitated by the Government Bill, but the wayleave difficulty is only *one* cause of the present inadequate service. Everything seems to point to the ultimate acquisition by the Government of the entire telephonic system of the United Kingdom. Then why take two bites at the cherry?

REVIEWS.

Traité Pratique d'Électricité. Par Felix Lucas. (Paris: Baudry et Cie.) To be obtained from *The Electrician* Printing and Publishing Company, 1, 2, and 3, Salisbury-court, Fleet-street, E.C.

While this work undoubtedly contains a very large amount of valuable matter, we cannot congratulate the author on his choice of subjects or on his arrangement of them. The book professes to be written chiefly for technical readers; yet the first part of it, consisting of no less than 160 pages, is entirely devoted to the mathematical theory of electricity. The writer has shown great skill in dealing with this difficult part of the subject; and although most of the proofs given are necessarily only slightly modified forms of those previously published, yet a very fair amount of originality has been shown in the arrangement of them, and in the introduction of simple geometrical methods and illustrations. A practical treatise should, however, approach the subject from the physical side. The mathematical theory of potential, and the discussion of Green's and other analogous theorems, are quite out of place in a work of this kind, however admirably they may be handled. The notions conveyed are not such as are needed in the latter part of the book, and the few practical ideas which are really necessary cannot possibly be gained from a merely analytical treatment of the subject. Indeed, much that is inserted in theoretical works on electricity might be with advantage reserved entirely for purely mathematical treatises. The elaborate theory of solenoidal and lamellar distributions of magnetism must always appear a waste of time to anyone acquainted with the eccentricities of iron; and it seems absurd to discuss the law between current elements, as is done at great length in Chapter VIII., when only closed circuit currents exist.

Besides this theoretical portion of the book there are five other parts, entitled electrical measurement; cells, accumulators, and electrostatic machines; dynamos; the transmission, distribution, and transformation of electrical energy; and finally the technical applications of electricity. The chapters are of irregular merit, some being excellent, and others very short and scrappy. The best part of the book is that dealing with dynamos. The character of the fluctuations of the armature current in various types of machine is considered fully, many new diagrams being given in illustration. The magnetic circuit and the phenomena of hysteresis are also well treated.

Several diagrams are given illustrating the properties of characteristic curves, and in particular a method is given for obtaining the characteristic of an alternator, taking into account the inductive nature of the armature. The design of dynamos is illustrated with an example worked out numerically; a novel and praiseworthy feature of the book. The work really deals with too many subjects to treat them

Digitized by Google

at proper length; and this fault is very apparent in the second part, which could be amplified with much advantage. The chapter on transformers discusses the theory of them in the usual unsatisfactory manner; for after stating distinctly that the coefficients in the equations cannot be considered constant, the writer proceeds to treat them as if they were. In this way results are obtained which are of slight value in theory, and of no value in practice. To assume that the coefficients are constant is to assume that there is no loss of energy in the iron core; and as this waste of energy is the greatest waste which occurs in transformers, the assumption is absurd from a practical standpoint.

A rather fundamental mistake of the author is to use the terms "watt," "watt second," and "watts per second" over and over again, as if they had identical meanings. This mistake cannot be excused in the writer of a text-book.

The book consists of 600 pages of well-printed matter, and is plentifully illustrated.

Die Versorgung von Städten mit elektrischem Strom. By F. Uppenborn. (Berlin: J. Springer; and Munich: R. Oldenbourg.)

This book is a compilation of the Reports made for the Congress of the German Municipal Authorities on the occasion of their visit to the Frankfort Exhibition last August. The work of the editor seems to have been confined to arranging the Papers which were supplied by the various firms at the invitation of the Exhibition Committee in alphabetical order. This is to be regretted, as owing to the omission of all mention of central stations built by one or two of the best-known foreign companies, the publication just falls short of being thoroughly representative of continental practice. If the book is to be regarded as anything more pretentious than a collection of Papers (as would appear to be the case from its title) it would have been much better if the recapitulations of various methods of distribution and so on had been put together at the commencement. As it is, practically identical descriptions (of the three and five-wire systems, for instance) are repeated in different Papers.

The descriptions of central stations that are given leave little to be desired; and with the numerous beautifully got up plates will serve to give those who were not so fortunate as to get to Frankfort last year a very good idea of the great difference that exists between electrical practice on the Continent and in England.

Continental Electric Light Central Stations. By Killingworth Hedges. (London and New York: E. and F. N. Spon. 1892.)

Like "Die Versorgung von Städten mit elektrischem Strom," of which nearly the whole of the present work is a translation, this book would be greatly improved if the elementary descriptions interspersed throughout it were collected together and thoroughly boiled down. A certain amount of arrangement is aimed at, Part I. being devoted to high-tension systems, and Part II. to low-tension distribution. A summary of the central stations described is also given. An error occurs both in this and in the text in respect of the Pontresina installation. The transmission in this case is not affected by alternating currents, but by direct ones, although by coupling three machines in series a tension of 4,500 volts is obtained. The author's descriptions are not always quite satisfactory; this is specially noticeable in his treatment of the multiple-phase systems, and also of Bláthy's alternating-current meter, which is practically nothing but a rotating field motor. His method of expressing himself is, in several places, worse than vague; we are apparently told, for instance, on p. 9, that the Zipernowsky cut-outs, "which are somewhat after the Hedges system," are all of 10 H.P. In dealing with the Cassel station he does not evidently think it necessary to explain how "the usual difficulty of starting these (alternate current) motors is met by using the accumulators to bring up their speed." A reference to the German shows that it is done by running as motors the continuous-current dynamos to which the alternator is coupled. In his explanation of the ground plan of the Barmen station, on p. 78, he gives "cart-house" as the equivalent of "waagehaus." The picture ought to have saved him from this error.

In Part III. the author gives some good remarks on the position of gas companies with regard to electric lighting, and on the cost of the electric light abroad, which to a great extent explain the rapid extension of the system of distribution from central stations on the Continent. The table on p. 198, giving the equivalent price of gas compared with electricity at various prices per unit, although it does not take into account the effect of running at high efficiencies on the life of glow lamps, will be useful for forming comparisons of the cost to consumers in many towns where renewals are undertaken by the company. The "explanation of technical terms" at the end contains some poor definitions, and as it includes many words that do not occur elsewhere in the book (unless it is in the advertisements, *e.g.*, "carboid,") it would have been better omitted.

Most of the remarkably fine illustrations in the German original are also included in the present volume.

The Illustrated Catalogue of the "Compactum" Specialities. By John Kirkaldy and Co. (Limited), 40, West India Dock-road, London, E.

This publication, although styled a "Catalogue," contains a considerable amount of interesting information and articles on feed-water heating and purification for boilers, together with many useful engineering tables and data. Drawings showing general arrangements of the connections and sections of feed-water heaters, valves and pumps, are given, as are also descriptions of the various manufactures of the firm.

There is an article on condensing and heating, in which various reasons and data are given proving that coiled tubes give very much more efficient results than straight tubes,—in one case a thermal conductivity of 914·4 B.T. units per hour per square foot of heating surface per degree Fahr. of difference of temperature between inside and outside of tube, which is nearly the same rate as Joule obtained by passing water through the annular space between two tubes, the inside one carrying steam, when 1,000 units per degree difference of temperature were obtained. The importance of supplying hot feed to boilers is emphasised by the statement that in a boiler 18ft. long with the temperature at the bottom 60° F., and the steam at the upper part 324° F., there is a difference in expansion of $\frac{3}{8}$ths of an inch between top and bottom; hence severe straining would result. To meet this, more especially on board ship, but also in those land installations where perhaps neither the waste gases nor the exhaust steam can be conveniently utilised, Messrs. Kirkaldy recommend their live steam-feed heater. They claim that, besides obviating the straining of the boilers as well as purifying the feed-water to a great extent, it will give an actual economy in the amount of coal consumed. As the heat imparted to the feed-water is actually derived from live steam, this may at first sight appear somewhat inconsistent with the laws of thermo-dynamics; but it is well known, and proved by experiment, that heating surfaces are more efficient when in contact with water approaching boiling point, owing to the more rapid circulation as compared with colder water, while grease and other impurities are kept back in the heater, the result being equivalent to an augmentation of the boiler-heating surface. The importance of eliminating pernicious impurities from the feed-water is treated; and it is mentioned that a boiler evaporating 1,000 gallons per hour of water containing 30 grains of solids per gallon would collect 100lb. of deposit in 24 hours.

We are glad to observe that the practice of embodying in trade catalogues information useful to those for whom the catalogue is intended is a growing one; and Messrs. Kirkaldy are certainly not behind others in this respect. The catalogue is well printed and bound.

THE DETERMINATION OF CURRENTS IN ABSOLUTE ELECTRO-MAGNETIC MEASURE.

BY G. F. C. SEARLE, M.A.

(*Continued from page 482.*)

§ 72. **Advantages of the Current Weigher.**—It appears then that if the fixed coils are so arranged that their action upon the suspended coil is a maximum, the only quantity which has to be found with great accuracy is the ratio A/a. To this feature Lord Rayleigh attaches great importance. "The ratio of galvanometer constants can be accurately determined by the purely electrical process of Bosscha without linear measurement of either; and from this ratio we can pass to that of the mean radii by the introduction of certain small corrections of the second order." The theory of this method was explained in § 29.* "In this way all that is necessary for the absolute determination of currents can be obtained without measurements of length or of moments of inertia or even of absolute angles of deflection. The forces are, however, evaluated in gravitation measure, so that the final result requires a knowledge of gravity at the place of observation; but except through this quantity there is no reference to the units of space or time."

Thus in the ideal state of things, when dM/dx is a function of A/a only, an estimation of a current by a current-weigher involves only two observations of the first importance, viz., the determination of the ratio of the radii of the fixed and suspended coils, and the determination of the mass whose weight balances the electro-magnetic force experienced by the suspended coil. The first of these quantities is a constant of the instrument, and may be determined once for all. The second quantity has to be measured at each observation of the strength of the current; but this is exactly the same as the ordinary process of weighing, and is quite simple and very accurate. There are, of course, some other observations to be made, but these appear only in the form of small corrections.

In Lord Rayleigh's current-weigher the distance between the fixed coils was not adjustable. They were arranged in the Helmholtz fashion, so that the distance between the coils is equal to the radius of either. This is the ideal construction when the radius of the suspended coil is very small compared with that of either of the fixed coils. When, as in Lord Rayleigh's case, the ratio a/A is not very small, the fixed coils should have been somewhat nearer together than was actually the case. Thus the force experienced by the suspended coil was not quite a maximum, and accordingly the calculated force was not quite independent of small uncertainties in the measurement of the distance between the two fixed coils. But in Lord Rayleigh's apparatus the error introduced into the calculated value of the current by an error of 1 per cent. in the measurement of the distance between the two fixed coils only amounted to ·14 per cent., while this distance was easily measured with very considerable accuracy. Thus Lord Rayleigh was fully justified in the hope that his work was practically free from any error due to uncertainty in the distance between the fixed coils.

§ 73. **Insulation of the Coils.**—If the reader will refer to § 49 he will find that the attraction per unit current between a pair of coils of radii A and a, placed at a distance A/2 apart, was proved to be approximately $6\pi^2(\frac{4}{5})^{\frac{1}{2}}a^2/A^2$ dynes. (In § 49 the π^2 has been omitted by a clerical error.) If there are n turns on the fixed coil and n' on the moveable coil, the force is

$$F = i^2\, 6\pi^2(\tfrac{4}{5})^{\frac{1}{2}}\, n\, n'\, a^2/A^2.$$

$$= h\, i^2\, n\, n'\, a^2/A^2, \text{ say.}$$

Also if β be the ratio of the galvanometer constants for the fixed and suspended coils, we have by § 29 $\beta = n\, a/n'\, A$, approximately, so that $a^2/A^2 = \beta^2\, n'^2/n^2$.

Thus we have $\quad \text{Force} = h\, \beta^2\, i^2\, n'^3/n.$

$$\therefore \text{ current} = \beta^{-1}\, h^{-\frac{1}{2}}\, n^{\frac{1}{2}}\, n'^{-\frac{1}{2}}\, (\text{force})^{\frac{1}{2}}.$$

Thus an error in n', the number of windings on the suspended coil produces in the final value of the current three times the effect of an error proportionally the same in the value of n. A defect in the insulation of one turn of wire from the next, causing one or more turns to be practically short-circuited, produces the same effect as a diminution in the number of turns. Hence the insulation of the wire must be very carefully seen to.

Lord Rayleigh found that the coils of the electro-dynamometer were well insulated from the brass frame on which they were wound, but he does not record any experiments made to test directly the insulation of the turns of wire one from the other. An indirect test was obtained by the comparison of the galvanometer constant of each of the fixed coils with that of the suspended coil. The two numbers obtained were 2·60067 and 2·60072. Since the mean radii and dimensions of the sections of the two fixed coils are very nearly identical this furnishes a proof that the insulation from turn to turn is good.

The suspended coil gave rise to much more trouble. Careful measurements were taken during the winding of the coil, but the galvanometer constant deduced from them agreed very badly with that found by comparison with the coils of the electro-dynamometer. This gave rise to the suspicion that several turns were short-circuited by a false contact. To put the matter to a further test Lord Rayleigh wound a second coil of the same dimensions with the same number of turns of wire. The two coils were placed co-axally close together, and so connected in series that a current would flow in opposite directions in the two coils. The circuit was completed by a galvanometer of long period. Under these circumstances when one pole of a very long steel magnet is thrust suddenly through the opening, there should be no effect upon the galvanometer if the insulation is good; but if any of the turns of one of the coils are short-circuited, the other coil will of course have the advantage, and the galvanometer will indicate a current in the corresponding direction. It was found in fact that the second coil preponderated, and that 13 turns had to be put upon the first coil to obtain a balance. "With proper precautions this method of testing seems satisfactory, being approximately independent of the mean radii of the coils compared." A second test by a different method made by Mr. Glazebrook led to the same conclusion, viz., that the insulation was defective. The coil was accordingly unwound, and then several bad places in the wire were detected.

The ring was wound with fresh wire and its insulation tested by a very delicate method devised by Lord Rayleigh for this purpose. Four similar coils of fine wire, wound upon wood and of the same mean diameter as the ebonite "suspended" coil, were arranged so as to form a Hughes' Induction Balance.* If the distances of the four coils are adjusted by screw motions to an exact balance so that no sound is audible in the telephone, the introduction of a tertiary circuit between one primary and secondary causes a revival of sound whose intensity depends upon the conductivity, &c., of the tertiary circuit. A single circlet of copper wire ·004 inch in diameter gives a very distinct sound. When the ebonite coil, with its ends unconnected, is introduced, the sound is audible, but much less than that from the fine copper circlet. "Part of this effect may be attributed to its finite capacity as a condenser, in virtue of which sound might be heard in any case; but it is probable that the insulation is, in reality, somewhat imperfect. The closing of the circuit through a megohm gives a distinct augmentation of sound; and thus it is evident that the insulation, if not perfect, is at any rate abundantly sufficient for the purposes of the present investigation."

ERRATUM.—In the last equation of § 49 insert π^2 on the right-hand side.

(*To be continued.*)

* In this method only the *relative* values of the resistances are required. The comparison is entirely unaffected by any uncertainties in the value of the ohm.

* S. P. Thompson. "Elementary Lessons on Electricity and Magnetism," § 438.

AN IMPROVEMENT IN THE METHODS OF INDUSTRIAL ELECTROLYSIS.

Of late years that branch of electro metallurgy which is concerned with the smelting of metallic ores by means of the heat generated between electrodes placed in opposing position after the manner of those in an arc light has developed with far greater rapidity than its elder brother, the electrolysis of aqueous solutions. On the one side is the Cowles furnace and its many derivatives and congeners, and on the other the best that can be mentioned is the Elmore process. It is true that various methods for manufacturing aluminium and producing sodium and magnesium, which involve definite electrolytical decompositions, and more than one process for the manufacture of "heavy chemicals," such as bleaching powder and caustic soda, have been recently attempted or realised; but the former depend largely on the mere heating effect of the current, and the latter are at present in a somewhat provisional stage, and in consequence cannot be reckoned among substantial industrial advances of electrolysis proper.

A consideration of the principles involved in the reduction of metals by some form of electric furnace, and in the electrolysis of a compound of the metal to be reduced in a state of aqueous or igneous fusion, respectively, leads irresistibly to the conclusion that the present preponderance of the former method is in a sense fortuitous, and is unlikely to be permanent.

The beautiful selective action of a current when applied under proper control to the work of electrolysis must always be a factor of importance wherever the maintenance of a reaction between comparatively narrow limits, or the obtainment of a product of a definite degree of purity, is a matter of concern. The possibilities of advance in technical operations are well foreshadowed by what has been already done in the domain of analytical chemistry to evolve electrolytical methods of general applicability from a few specific instances where the principle of electrolytic separation had found an isolated sphere of utility.

When primary batteries were the only practicable source of electricity, a few far-seeing inventors applied themselves to the problem of producing some substance of commercial value as a bye-product, the price of which should go to reduce the cost of generating current from that extremely expensive fuel, zinc. The artificial difference between the value of any given commodity in terms of energy and money made the realisation of this design perfectly possible. Up to the present, however, it has not been achieved, probably because of the limited range of marketable materials that can be thus produced, the expense that would be involved in their collection, and, above all, because of the banishment of the primary battery, for all but special purposes, as a source of current, by the evolution, now almost complete, of the dynamo. Although the application of this idea to the primary battery is obsolete, yet the idea itself is by no means necessarily worn out and valueless. It merely needs adaptation to an altered environment to develop from its encysted state and become active and fruitful.

The deposition of a metal from a solution of one of its salts by the passage of a current is a remarkably simple operation on paper, but is apt to prove troublesome if attempted without a complete knowledge of the best conditions under which to work. Even when a metal like copper is taken as an instance, the deposition of which has been practised on a large scale for years, difficulties at once arise when so elementary a feat as the production of an unusually thick sheet has to be accomplished. In this and similar instances much can be learnt from what is already actually done in the laboratory for the purpose of analytical separation. The direction in which advance is possible was recently clearly indicated in a Paper read before the German Society of Applied Chemistry, by Dr. W. Borchers, who laid particular stress upon the necessity for seeking guidance from the store of information that has been accumulated primarily for the benefit of the analyst. It is obvious that the electrolytic separation of a metal from an aqueous solution of one of its salts is much aided by the exclusion of strong acids in the free state, as they tend if present to undo the work of electrolysis by redissolving it. Further, equal care is necessary to get the utmost advantage of that portion of the energy consumed which would, under primitive conditions, be expended in the liberation of oxygen at the anode. Of course, when the sole function of the current is to transfer metal from a crude anode to a pure cathode, as in copper refining, the question does not arise; but when an insoluble anode is used, and the metal is reduced in the same positive sense as in ordinary methods of smelting, the utilisation of the oxygen or potential oxygen becomes a matter of serious concern. The best plan would appear to be to provide some substance at the anode, the oxidation of which would yield a product of commercial value. In analytical chemistry the first condition is fulfilled by transforming the metallic salts of the strong mineral acids into those containing comparatively weak organic acids, and for this purpose the oxalates, tartrates, citrates, benzoates and cyanides are freely used. The products of the oxidation of these, as far as their commercial value is concerned, are naturally a matter of indifference to the analyst. To the industrial chemist, however, the first cost of the salts in question, and the value of the substances formed by their oxidation, are of the greatest moment, and of those named, none offers him the smallest chance of profit. The most likely substances to prove remunerative are various members of the series of bodies obtained by the distillation of coal tar, especially as among them are several natural groups of bodies of immediate industrial significance. Prominent among these are the cresols, a group of three bodies belonging to the class of substances known as phenols, the first member of which is more familiar under the title of carbolic acid. The fact that they are insoluble in water does not prevent their use, as they are readily soluble in solutions of caustic alkalies, and should an alkaline electrolyte be inadmissible, they may be readily converted into their sulphonic acids, and these, or their salts (sulphonates), possess two properties which render them well suited for electrolytic purposes, viz., ready solubility and good conductivity. As the products of their systematic oxidation include such substances as the oxybenzoic acids, and some of the quinones, there should be little difficulty in turning them to account. In the formation of such substances the ease with which reactions are controlled, to which we have already alluded as one of the most striking advantages of electrolytical operations, could be utilised to the full in securing the production of the maximum quantity of the most valuable substance, greater commercial efficiency than can be secured when the reactions are brought about by purely chemical means being thus possible. In addition to this the use of costly special oxidising agents each adapted for one reaction or group of reactions to the exclusion of others chemically dissimilar, could be done away with, reliance being placed on the regulation of the conditions under which the current was allowed to act.

By the adoption of the principle that it is almost as easy to turn out valuable bye-products simultaneously with the production of the material for obtaining which the installation was primarily intended, there is little doubt but that many enterprises whose prospects, as long as they stick to the groove of manufacturing routine, can be moderate at best, might find a field that would well pay for the reaping. It might even come about, as has already happened in more than one branch of industry, that the bye-product and the main-product changed places in order of importance.

OIL AS AN INSULATOR.

The following is the authorised abstract of the interesting discussion on Prof. Hughes' Paper on this subject, which took place at the Institution of Electrical Engineers, on Thursday, the 17th inst.:—

Mr. CAMPBELL SWINTON had made some experiments on the difference of sparking distance in air and in oils; his results did not agree with those of Prof. Hughes', but made oil much worse. He used as a source of E.M.F. an induction coil capable of giving a 7″ spark in air, the distance he found from one to three times as long in air as in oil. Possibly his oils were not of so good a quality as Prof. Hughes'. He would like to know if Prof. Hughes dried his oil. He had tried doing this, but found that after drying it would re-absorb water, and, therefore, preferred tests on undried

Digitized by Google

samples as being of more practical value. When using paraffin oil he found a distinct deposit of carbon at each discharge.

Mr. JOHNSON (of Johnson and Phillips) rather objected to the alleged anticipation of Brooke's system. Prof. Hughes' system was one with an insulated pipe (gutta-percha, &c.). Mr. Willoughby Smith had tried it and found it of little use. He objected also to the idea of the oil closing up faults in the gutta-percha covering of a cable on the same principle that it was bad to use tarred yarn on gutta-percha core; it temporarily closed incipient faults and thus prevented their detection. His firm had a line laid at their works on the Brookes' system, which had been repeatedly tested at 15,000 volts, and had stood it perfectly. There was a great difficulty in getting the right quality of oil. The best method of testing, he thought, was to pass it all through a narrow orifice and test it electrically as it passed.

Mr. GRAY called attention to a Paper by Rousseau in (?) 1826, on the insulation resistance of oils. He himself had made some tests on specific resistance by direct deflection with 100 cells, his results were as follows:—In C.-G.-S. units, 10^{20}; rape oil, ·5 to 5; lard oil, 2 2 to 5; colza, 1 to 15; cotton seed oil, 53; and linseed ·31 to ·8; he then measured the spark distance with 10,000 volts, and took the resistance again, which was always less than before with vegetable oils and paraffin. With thick resin oil he found when the electrodes approached to such a distance that 10,000 volts once gave a spark, that 2,000 volts would then give a spark through the same distance. Having measured some resin oil in 1887 with 100 cells he found in 1889 a higher specific resistance with 25 cells, but a lower one when measured with 100 cells as before.

Mr. VARLEY preferred to test the air and oil in series, instead of parallel, as Prof. Hughes did, *i.e.*, he put one electrode under oil, and the other some distance above it. He had tried to make a condenser with three thicknesses of bank-post paper between the plates, immersing it in dried paraffin, but it broke down at from 300 to 400 volts.

Dr. FLEMING said that no one need be afraid of putting transformers in oil, as Ruhmkorf had used it for insulating his coils in 1851. A description was also given by M. Gine, in 1854, of a coil wound in cotton-covered wire, which was desiccated in vacuo and then kept under turpentine oil—from this he got a 12″ spark. A Paper by Poggendorf on the same subject would be found in *Phil. Mag.*, July, 1855, using vegetable oil or oil of turpentine. He would suggest, on the analogy of alloys having a higher specific resistance than pure metal, that perhaps some mixture of two or more oils might be found which would give higher insulation than pure ones.

Mr. DONOVAN asked why the Post Office did not take up oil insulators, and wished to know how many miles of oil-insulated cable were now in use. He said that if vegetable oil were mixed with paraffin the latter would evaporate and leave the vegetable oil behind.

Mr. CUTHBERT HALL had found that the temperature co-efficient of oils was very high, the resistance varying as much as 20 per cent. between 16 degrees and 24 degrees. The best insulating oil he considered to be half of "first run" oil and half of solid resin. He had found jute to be a very good insulator; the insulation of a dry jute-covered cable was actually lowered by impregnation with oil. Transformers he preferred to slowly heat up to a high temperature and then immerse in resin oil. He confirmed Mr. Gray's experience of continuous sparking in paraffin when the first spark had passed, but resin oil did not behave in the same way.

The PRESIDENT said there had been a good deal of loose expression with regard to the resistance of the various oils. "High resistance" had been used by different speakers to mean (1st) actual high specific resistance in the same way that one speaks of the specific resistance of a metal; (2nd) high resistance to a spark passing through the mass of the oil; and (3rd) high resistance of the surface of the film. Which of these was Mr. Hall referring to when he mentioned the high temperature coefficient?

Mr. HALL said he measured the actual resistance between two metal plates wholly immersed in the oil, and therefore referred to the first meaning.

Mr. KAPP said the first transformer he tried to insulate with oil broke down in two or three minutes. It was wound with silk-covered wire. He then had the coil unwound and the wire rewound after, passing through a bath of boiling paraffin on its way to the winder. The transformer then ran with 17,000 volts, and had never broken down again.

Mr. TROTTER asked what was the real weak point in an oil cable. Was it the oil itself or was it the solid insulator, hemp, paper, or gutta-percha?

Prof. FORBES said that just at first cables were insulated with gutta-percha, as at Paddington. This was soon given up, because the wires were run so hot that the gutta-percha got very soft. To-day, however, cables were never run hot, and he thought it quite possible that gutta-percha might be tried again with good results. He also thought that something should be done to try and improve gutta-percha by treatment with oil.

Mr. PREECE said Mr. Donovan had asked why the General Post Office did not use oil insulators and Brookes' cables. The objections to the former in England were that the rain got under the oil (light oil having been used in those he tried), that the wind blew the oil out, and that spiders could not be kept from spinning their webs over them. He had been much impressed with Mr. Brookes' system when he first saw it, and had a 40-wire line put down from Vauxhall to Clapham Junction. They had considerable trouble at first with bad joints in the tubes, but even when these were put right the water got in when they were using light oils, of which very large quantities were lost. He then got some special heavy oil from America, but could not get it to run far along the pipes. However, the wires still tested well, even when the oil had leaked away, and they were only separated by impregnated cotton or hemp, say 1 megohm per mile. This was quite good enough for practical work, and was steady, and a great improvement over an air line, which might test 100,000 ohms a mile one day and as many megohms on others.

Mr. SWINBURNE said the "healing" property of oil insulation did not exist for transformers. When a coil once sparked across it was ruined. In a transformer there were many H.P. behind the spark, and when it passed an arc at once followed it. He had tried drying the oil chemically in various ways, but had found it quite useless. The real insulator he considered to be dry cellulose, the oil merely keeping the moisture out. Perfectly dry cotton, even when thoroughly saturated with oil, will get moisture from the atmosphere if exposed to it for a short time. When jointing impregnated cables three or four feet should be cut off each of the ends, and the joint made at once. The oil for insulating transformers must be heavier than water, or moisture will get down, and if it touches the covering of the wire at any point it will spread all over it.

Mr. JOHNSON, referring to Mr. Preece's remarks about oil insulators, said that in the line on which they were tried by the Post Office he himself had counted some six or seven common shackle insulators, and that the end of the line was connected to a quarter of a mile of old gutta-percha cable in an underground pipe. This, he thought, was quite enough to account for the poor results obtained.

Prof. HUGHES, in reply, said that the high results which he gave were the best he could get. The very high ones were for sparking distance with the "impulsive rush," working with Leyden jars. He found the resin oil of to-day not nearly so good as that which he used in his earlier experiments. With regard to the Brookes system, he liked Mr. Brookes when he brought his system over, and said nothing about his own previous work in the same direction. He noticed, however, that Mr. Brookes had disclaimed a good many things in his patents, and now relied principally on the use of stand pipes and on heating the oil. In reply to Mr. Trotter he never found any covering equal to gutta-percha in resistance. He agreed with Prof. Forbes that gutta-percha might be much improved by oil treatment.

Mr. CAMPBELL SWINTON, referring to Mr. Swinburne's remarks, pointed out that Mr. Tesla said his transformer constantly broke down and "healed" itself.

Mr. SWINBURNE replied that Mr. Tesla was only dealing with infinitesimal currents and small power. In an ordinary commercial transformer the fact was as he had stated—there was no healing power.

PHYSICAL SOCIETY.

At the usual fortnightly meeting of this Society on March 11, 1892 (Prof. A. W. Rücker, F.R.S., Vice-President, in the chair), Mr. H. M. ELDER, M.A., read a Paper

"On a Thermodynamical View of the Action of Light on Silver Chloride."

In the decomposition of silver chloride by light chlorine is given off, and a coloured solid body of unknown composition (sometimes called "photochloride") formed, the reaction being indicated by the formula $n\,AgCl = Ag_n\,Cl_{n-1} + \frac{1}{2}\,Cl_2$. If the experiment be carried out in a sealed vacuum the chloride is darkened up to a certain point, but regains whiteness when left in the dark. These facts have led the author to believe that the pressure of the liberated chlorine is a function of the illumination or intensity of light falling upon the chloride in the same way as the pressure of a saturated vapour is a function of the temperature. Since illumination is a quantity in many respects analogous to temperature he considers it not unreasonable to apply thermodynamic arguments and regard chlorine in presence of silver chloride and "photochloride" as the working substance in a "*light engine.*" He therefore supposes a Carnot's cycle to be performed on the substances at constant temperature, the variables being pressure, volume, and illumination.

A Paper

"On Choking Coils"

was read by Prof. PERRY, F.R.S. Regarding a choking coil as a transformer with one primary and many secondaries represented by the conducting masses, he pointed out that all the secondaries might be replaced by a single coil of n turns and resistance r ohms, short-circuited on itself. Assuming no magnetic leakage the equations for the two circuits at any instant are $V = RC + N\dot{\theta}I$ and $0 = rc + n\dot{\theta}I$, where N and n are the turns R and r the resistances, I the total induction in 10^8C.-G.-S. lines, &c., and C and c the primary and secondary currents respectively, $\dot{\theta}$ standing for d/dt. Since the exciting current C is all important in choking coils, and its value depends on the law of magnetisation, the equations are treated in a different manner to that adopted in ordinary transformer calculations. Expressing the cyclic magnetic law in a double Fourier series the value of A (viz., $NC + nc$) is deduced, and when V or I is given as a periodic function of the time, C may be calculated. Assuming $V = V_0 \sin kt$ the author finds

$$C = \frac{V_0}{N^2 \sigma k}\left[\sqrt{1 + 2e\sin f + e^2}\cdot\sin\left\{kt - 90 + \tan^{-1}\left(\tan f + \frac{e}{\cos f}\right)\right\} - b\cos 3kt - m\cos 5kt\right],$$

where $e = n^2\sigma k/r$ being the eddy-current term, f is the hysteresis term, and b and m constants depending on the law of magnetisa-

Digitized by Google

tion. For ordinary transformer magnetisations $b=0{\cdot}2$ and $m=0{\cdot}05$. From the above expression it will be seen that if there is no hysteresis (*i.e.*, $f=0$), the effect of the eddy currents e is to increase the amplitude of the important term and to produce a lead of $90° - \cot^{-1} c$, whereas the effect of hysteresis without eddy currents is to leave the amplitude unaltered and produce a lead f. Putting $f=0$ gives results in accordance with experimental observation, hence the author is inclined to believe that there is no hysteresis in transformers. He also points out that the higher harmonics must exist, and shows that a choking coil with finely divided iron may prove a method of increasing frequency by mere magnetic means.

Taking the case of a 1,500-watt transformer (2,000 volts) unloaded, in which the loss in eddies was 40 watts, it is shown that a secondary of two turns and resistance 1·9 ohms could replace the eddy current circuits. Assuming constant permeability and no eddy currents, the value of C comes out $0{\cdot}07398 \sin (kt - 90°)$, whilst with eddy currents and some saturation but no hysteresis $C = 0{\cdot}07911 \sin (kt - 69°{\cdot}2) - 0{\cdot}0148 \cos 3kt - 0{\cdot}0037 \cos 5kt$.

Dr. FLEMING said he was working on the subject of choking coils, and had found that in closed circuit transformers unloaded, the real watts were about 0·7 times the apparent watts. This, on the assumption of sine functions, would indicate a lag of about 45°. A similar rule for open-circuit transformers was much needed. It was important to know what size of core and coil was required to choke down to a given current.

Dr. SUMPNER thought it better to treat the subject graphically rather than by analysis, and described a construction whereby the fundamental equations could be readily integrated.

Prof. PERRY said he had reason to think that ordinary hysteresis curves were not applicable to transformers unless one knew the cyclic curves it was impossible to work graphically. By analysis of the experimental E.M.F. and current curves, one could work backwards and find the true magnetisation curves.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.—TUESDAY, MARCH 22ND.

NEW TELEPHONE COMPANY BILL.

On the motion for the second reading of this Bill,

Sir J. FERGUSSON said: I think the House will perhaps allow me to state the course which the Government find it necessary to take with regard to this Bill, and incidentally the policy which they intend to pursue regarding the very important questions concerning the telephone system. The Bill now before the House is in itself moderate in character. It really seeks to obtain for the New Telephone Company statutory powers similar to those provided for the Post Office by the Act of 1863, except in one particular. I do not know that the powers asked would be excessive if it were desired by Parliament that private telephone companies should be placed in possession of separate statutory powers. That has never hitherto been the case. But the telephone interest is in a very different position to that of gas, electric lighting, water companies, and so forth, because none of these touch or trench upon the perrogative of the Crown; but it has been decided by the High Court of Justice that telephones are telegraphs, and consequently are the monopoly of the Post Office. Accordingly, no separate powers have ever been conferred upon telephone companies, but they have carried on their proceedings under licence from the Postmaster-General. I need not trouble the House with the whole history of the telephone question. The House is familiar with it, and only a few years ago it was the subject of inquiry before a Select Committee. Still I should like to remind the House that the policy pursued by my predecessors, to whatever party they belonged, was to grant licences to commercial companies for the erection and maintenance of telephones. These licences, at first restricted, were afterwards made universal, and, in fact, 13 companies were granted powers extending over the whole kingdom. It was intended by my predecessors that there should be thus commercial freedom, and that the public might be efficiently served by the competitive efforts of these companies. The result cannot be said to have been wholly satisfactory, for gradually these companies have been nearly all amalgamated or absorbed by one large company, the National Telephone Company, which has made greater advances than any other undertaking of the kind in this country. There are, however, some absorbed in a smaller group, headed by the New Telephone Company, by whom the present Bill is promoted. There have been many representations of late made by important public bodies of the inadequacy of the present telephone system. Only yesterday I had a very large deputation from the London Chamber of Commerce, who represented that it was very desirable—in fact, that it was really important—that Her Majesty's Government should bring in a general powers Bill, so as to afford facilities for the development of the telephone, not only in the metropolis, but also with regard to inter-town service all over the country. In view of what I believe to be the very prevalent opinion, and of the constant policy of the Post Office, it will be my duty on the part of the Government to oppose the second reading of this Bill, and *a fortiori* of the Bill promoted by the National Telephone Company, which is not at this moment before the House, but which has been read a first time, and which seeks powers much wider than have ever been asked by the Post Office. The fact is that owing to the failure of the intentions of the Government the telephone system has made less progress in this country than perhaps in any other country in Europe. Whereas in France and Germany it has made very great strides, so that a considerable percentage of the people are users of the telephone, in England a very small fractional portion only enjoy the use of these facilities. In London, the largest city in the world, not one fourth the number of persons are users of the telephone that there are in the City of Berlin. The form of licence issued by the Post Office has something to do with the hindrance to the development of the system. The licences confine the companies in their operations. They, for instance, restrict them from delivering messages, which is the process followed in France, where the telephones belong to the Government, and they cannot communicate with the Post Office except under considerable charges. They cannot make their lines along railways, roads, and canals, where the Post Office have the entire concession, without paying a very heavy wayleave. Ever since I have occupied my present office I have given my earnest attention to this subject with a view to devise a system which would facilitate instead of restraining the development of the telephone industry, and at the same time would sufficiently guard the Post Office monopoly, which, though an ugly word, really means guarding the interests which the public have acquired. I do not think that these two objects are at all incompatible, and it has been our desire to frame a scheme by which the greatest encouragement should be given to the development of the telephones, and that the Post Office should work entirely in alliance with them. That there is a real danger of the valuable telegraph property being injured by the telephones without due provision I can prove by the fact that, wherever the telephone system has been effectually developed, there the growth of the telegraph revenue has been checked. The telephone system has been more considerably developed between the large towns in Lancashire and Yorkshire than perhaps anywhere else; but in whatever part of the country it has been developed, there the growth of the telegraph revenue has been checked. But the concessions which might be made to the telephone companies mainly consist of these:—In the first place, messages might be transmitted from the telephones and communicated to the public telegraph wires, so that there might be free communication between the two. Messages might be sent from any telephone subscriber to be delivered to his correspondent. At present that cannot be done. Messages might be sent by post as letters, and they should receive the service of the express messengers. No charge shall be made in the post-office for the work of taking down telephonic messages and despatching them by telegraph or by post, and the wayleave now charged over railways shall be reduced from 20s. per mile per year to a nominal sum. And, lastly, the companies shall be allowed to establish call offices in post offices were possible. There are other possible concessions which, in the public interest, the Government are prepared to make while adequately securing the telegraphs, but they are mere matters of detail. Then, also, the Government are prepared to facilitate legislation giving certain moderate powers for the construction of telegraphs by their licensees. These concessions, if granted without corresponding provisions for the protection of the public revenue, would be very dangerous; for if the telephone companies were in communication with all the large towns, and sent messages all over the country, undoubtedly the system would to a large extent supersede the use of the telegraph, and consequently largely diminish the telegraph revenue. Therefore, it is an essential feature in the scheme, if carried out, that the Government should have possession of the trunk wires. It is our view that we ought not to interfere with the commercial business of the companies in establishing exchanges as widely as possible wherever their enterprise may lead them, but that the junction of those exchanges should be in the hands of the Government. The trunk wires should be in the hands of the Government in order that the public may have their portion of the sum paid for the message, in the same way as telegrams; but that would be fixed at a moderate rate, so as not to check the development of the telephone. As regards main lines in towns connected with several exchanges, it is desirable that they should be in the hands of the Post Office, because if telephone companies become largely developed there will come to be an infinity of thick cable wires connecting these exchanges, and, as in New York, the time may come when these might be inconveniently multiplied to the public danger; and the local authority, as in New York, might be compelled, at immense expense, to remove them from overhead and place them underground. If the rival telephone companies were to be possessed of the power of operating in the same towns or area, or possessed powers to take up the public streets and lay down underground wires, there would be infinite confusion and disturbance of traffic, and private rights might be encroached upon. But if the Post Office has power to make the main connections, they could lay wires side by side to accommodate all the different exchanges—the exchanges running separate wires for their own service; and so the work would be done with the least possible disturbance, and it would increase the accommodation to the public. But any such powers would be naturally viewed with great jealousy were they not exercised in strict harmony with the local authorities; and it is the intention of Her Majesty's Government, both in the additional powers they propose to confer and the additional powers which they propose to seek from the House, to carry the local authorities with them throughout. Another question is, How far is this extension of licences to proceed? It is contrary to sound policy that licences should be given to men of straw, who merely acquire them for the purpose of selling them and for levying blackmail, in a sense, upon existing companies and solid organisations; and, therefore, the view of the Government is that fresh licences should not be given all over the country. That almost follows on the desire of the Government to possess the trunk wires. Wherever the Local Authority are satisfied that a telephone exchange is desirable in their area, and the Government are satisfied that the licensees are in a position to carry out their undertaking, and that it is in the public interest desirable that they should have a licence, then they will be granted a licence for that area. It

Digitized by Google

is my intention on the part of the Government to move in a few days for leave to bring in a Bill to confer additional powers on the Post Office in regard to telegraphs and telephones. It would be improper for me now to indicate what those powers will be. They will be very moderate, and will not infringe any private rights, and in every case we shall carry the local authority with us everywhere. There will be a slight extension of existing powers where they are insufficient for the development either of this new modern enterprise, or of small extensions of telegraphs where public necessity requires. It is extraordinary how local authorities and private individuals can interrupt the making of most moderate extensions for months. I do not think I need go further into the matter just now, but I do not think the House will be prepared to establish private companies in so strong a position in opposition to Government telegraphs as would be created by this Bill; and I move, as a matter of form, that the Bill be read a second time this day six months, though I have every reason to believe that the promoters do not intend to press it in view of the statement I have made.

Mr. CALDWELL, in view of the announcement that the Government intended to introduce a Bill in a few days, moved the adjournment of the debate.

After a short discussion the debate was adjourned to that day week.

LEGAL INTELLIGENCE.

Lane Fox v. Kensington and Knightsbridge Electric Lighting Company (Limited).

MONDAY, MARCH 14TH.

Sir HENRY C. MANCE, examined by Mr. R. W. WALLACE, said that in the year 1878 the term "earth" meant a vast globe or reservoir, a common reservoir, the resistance offered to the passage of a current being practically nothing. Reading Lane Fox's specification as an engineer, he would have used the ordinary earth that a telegraphist would have used.

Mr. JUSTICE SMITH: What is the good of going over this again and again and again? I have had this dozens of times—all the same thing. I will tell you my own view at once about "the earth." It seems to me, subject to what I may hear in the speeches, that "the earth" means any return, but it is liable to be altered by the context in which it is used. It seems to me the number of eminent gentlemen who have been called agree that "the earth" meant any return, call it soil, or insulated or uninsulated wires, but is liable to be controlled by the context it is used in, in the specification, and that is for me. That is the sole point on that.

Cross-examined by Mr. MOULTON, WITNESS said that a conductor would answer the same purpose as the soil if it had resistance in it.

Mr. JUSTICE SMITH: Before the distribution of currents came in they had one current that used to go through all the lamps in line.—No, my lord, you will find a description of the multiple arc system before 1878.

Mr. HERBERT W. MILLER, examined by Mr. FINLAY, said that he was the resident engineer at the Kensington Court Station of the defendant Company. He first became connected with the Company in 1885. Before 1886 he was at Crompton and Co.'s works. He did not know of any installation where the system described in the plaintiff's specification was used. He did not think it was possible to work with that specification at all. The principal reason was that in the specification it was taken for granted that the accumulators were automatic regulators—that was to say, that they could be charged and discharged by increasing or decreasing the E.M.F. to a very small extent. He believed that it was absolutely impossible to send back large currents such as would be used in the central station through the earth. It was absolutely impossible either to charge or discharge the battery with a small increase or decrease in the pressure.

Mr. JUSTICE SMITH: That is the whole question—what do you mean by "small"?—I think it is absolutely impossible to charge a battery properly under from 15 to 20 per cent. rise in the pressure. In ordinary practice it is 25 per cent. As a general rule they started about 11 o'clock in the morning to charge the secondary batteries at Kensington Court. Witness then described by means of curves the process of charging the batteries. By working the dynamo to produce 115 volts, it took from 12.2 midday to 4 o'clock to get the pressure in the batteries up to 113½. The current at 4 o'clock was 70 amperes. It would then be necessary either to raise the pressure above the 115 or to keep charging at that low rate.

Mr. JUSTICE SMITH: And if you kept your charging at this very low rate, what then?—It would take you too long to get the batteries full. It would take about 10 hours longer.

Mr. FINLAY: The difficulty would not be avoided by increasing the area of the battery plates.—Witness did not think that at all possible. The pressure in the cell when charging being due to chemical action, it would be the same whether the cell was large or small. In a cell there was the internal resistance, and the resistance of the chemical action which was the result of the transmission of the electric force into it. The resistance of the cell would be diminished by increasing the size—the area, but the resistance due to the chemical action would not. They had an arrangement of switches, so that when the pressure of the cells rose they were able to move the switches with which the feeder was connected down to a cell where the pressure was at a normal amount. When the pressure dropped they were able to move the switch so as to introduce more cells, and thus keep up the voltage, and they continued charging the batteries until the reading of the meter in ampere hours showed them that the batteries were full. They used the same meter for the discharge.

Mr. JUSTICE SMITH: What is the meaning of an ampere hour? Supposing a man said 20 ampere hours, what does it mean?

Mr. FINLAY: It would mean that he could get 20 amperes for one hour, or one ampere for 20 hours.

WITNESS, continuing, said that the capacity of each of the batteries was 1,000 ampere hours. And the meter showed when they were full the bubbling really was going on the whole time of charging, but it began to bubble freely when it was about two-thirds to three-quarters full. It would not do to stop at that point. The battery would not be full up. The next time they tried to discharge the battery they would not get the full amount out of it, and it would be gradually decreasing each day. If they only put 600 amperes hours into the battery, they would be only able to take out about 500. If they only put into the battery each day exactly what they took out the capacity of the battery would gradually diminish, because of the loss which took place between each charge and discharge. Cells joined in connection with the mains on which the lamps were as proposed in Lane Fox's specification, would not regulate the pressure. If the batteries were supposed to be acting as regulators, and a number of lamps were turned off from the circuit, the extra current produced by turning out the lamps would go into the battery, and the fact of going into the battery would at once cause the pressure to rise. In the same way, if a large number of lamps were constantly lighted, and the current required for these lamps was taken out of the battery, the pressure would at once fall in the battery.

Mr. MOULTON: I think that is an admission of our whole contention?—In order to get over these defects, there not being automatic regulators ——

Mr. FINLAY: What would have been the effect of these changes you have been describing in the mains with which the lamps were in connection?—The pressure would be varying up and down continuously.

Mr. JUSTICE SMITH: What do you say the batteries do?—I say the batteries do not automatically regulate the pressure.

Mr. FINLAY: What is the use of the batteries? What do you use them for?—As reservoirs of electricity to be used during the time that we do not require to run the machinery.

How, in fact, do you regulate at Kensington Court Station?—We regulate by altering the speed of the engines and dynamos on the indication afforded by the voltmeter showing the pressure at the point where each feeder enters the mains.

Referring to the process of charging, WITNESS said they finished charging at the Queen's Gate Station about four o'clock to half past four; at the Kensington Court Station at about nine o'clock at night. The Queen's Gate Station was charged through the charging main. After half-past 11 the whole of the work was done from the accumulators themselves, the dynamos being stopped. They had to move the accumulator switches from five to six times between 11.30 and 7 a.m. They had to move the switch first of all five or six times to make the battery take up the whole of the work previously done by the dynamos. After that it was necessary to move the switch two or three times, as the lights are turned off before the station was shut up at about half-past 12 at night.

Cross-examined by Mr. MOULTON, witness said the current would not flow out of the batteries unless there was a tremendous difference in pressure; small variations would not be taken up by the accumulators. It was not true that if one crammed current in at a great rate, there was a very much greater resistance in the batteries, and they had to charge at a higher pressure. They could send 200 amperes through at practically the same pressure that they could send 20. They had a counting-meter, which also showed them the way the current was going. They had an ammeter on the batteries fixed in circuit. At one time they had the charging switch and discharging switch combined—one switch to do the two operations. They made the change some time in 1890, about October. At Kensington Station they found it very much more convenient to have both switches entirely independent, but at Queen's Gate there was no necessity to alter it.

Re-examined by Mr. FINLAY, WITNESS explained that he meant the difference in pressure required to put 20 amperes or 200 into a battery, when they had no internal resistance in the cell it was so slight it was practically the same pressure—it was so minute.

Mr. R. S. ERSKINE, examined by Mr. R. W. WALLACE, said he had been the Secretary of the defendant Company since soon after its formation. He went into the service of the Brush Company in 1881, either at the end of April or the beginning of May. Mr. Lane Fox was with the Brush Company at that time, and he took witness into his department. He remembered the exhibit that was prepared for the Paris Exhibition. The fittings were only wired with one wire, the fitting itself forming the return. At the Crystal Palace Exhibition in 1882 no batteries were used in Mr. Lane Fox's exhibit. He had something to do with the arrangement of the plant at the exhibition at 108, Queen's Gate. The batteries were used there to aid the dynamo. He was assistant engineer at the Vienna Opera House. There were four sets of batteries of 50 cells each.

Mr. JAMES SWINBURNE was then called and examined by Mr. FINLAY. He said that with regard to what was done by the defendants and comparing it with what was described in the specification, and what was claimed by the plaintiff in his specification, the points of resemblance were in using generating and consuming devices in parallel. The points of difference were in the way these were used. Mr. Lane Fox thought he would save half the drop of potential in the leads by the use of the earth. Next he proposed to place the batteries, dotted about the system, instead of at the generators. He proposed to run a practically constant current from the station. The defendants used switches in order to enable them to charge or discharge their batteries, whereas Mr. Lane Fox thought that the batteries would charge or discharge with a practically small variation. Reading from the specification, page 5, "When the electromotive force falls owing to the draught from the mains when the force is most used and needed," witness reminded the Court that there was a regulator keeping the electromotive force constant at the engine, so that the electromotive force at the station could not fall. The electromotive force from different parts of the system would fall owing to the draught in the mains,

Digitized by Google

The passage showed it was the fall due to the resistance in the mains that the patentee was considering. Quoting again from specification, page 5, line 3, "The number of cells in each of these batteries will depend on the electromotive force of the mains," witness said if the batteries there had not been dotted about all Mr. Lane Fox would have to do would have been to have said that 50 cells should be used. Mr. Lane Fox meant a different number of cells in different places. At line 16 he said, "Also a number of reservoir batteries as before explained," that meant dotted about as before; otherwise Mr. Lane Fox would have simply said, "Also a number of batteries." Assuming "the earth" to be an important part of the system, which it was, because Mr. Lane Fox wanted to get his electromotive force constant at each lamp, so that it should not vary; he wanted to reduce the variations by half by the use of the earth return, which he considered had no resistance. Witness proceeded to explain by aid of three diagrams the effect of dotting batteries about a system of electrical distribution. At the station in Case III. he assumed 100 volts kept constant by the regulator. There were 400 amperes coming from the station. Half-way along the pressure had fallen to 95 volts. It was charging a battery of 47 cells. 95 volts were going into the battery. 200 amperes were going into the battery with 47 cells. At the far end it had fallen to 90 volts, and there was a battery of 45 cells, also taking 200 amperes under 90 volts. Taking the same installation and putting a full load upon it, they got "Pressure fallen owing to draught in mains." There was still 100 volts kept constant by the regulator and still 400 amperes. There was a large number of lamps, and with varying voltages from 100 to 95 in the first half of the main. These just ran slowly down, taking 400 amperes. The middle battery at 94 volts discharged 200 amperes, and kept that level. Then further along there was another set of lamps taking 400 amperes, varying from 95 volts and running slowly down. At the far end there were the same cells, but they had now got 88 volts instead of 90, and they were discharging 200 amperes. The cells in this case, compared with Case II., reduced the variation in the lamps enormously. In fact, if that had worked it would have been a very clever invention. He did not, however, think that practically batteries could be worked in that way. In the first place, a battery would not charge and discharge usefully with such a small variation of pressure. He did not know whether it was a fair thing to say, but even if they did the batteries at that date were of no practical use.

Mr. JUSTICE SMITH: Not Planté's batteries?—Not the Planté of 1878, my lord.

Mr. JUSTICE SMITH: I thought that I had evidence that the batteries were good enough, only they did not know how to work them properly. Mr. Crompton said that.

The WITNESS: Might I suggest that there is a little confusion? I mean the Planté of 1878.

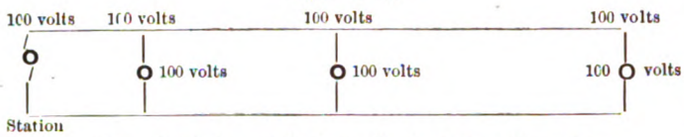
Mr. JUSTICE SMITH: Oh, no; Mr. Crompton was clear enough. Mr. Crompton's theory was that these batteries were all good, the whole lot of them—only he found out the way to work them, which nobody found out before. That was Mr. Crompton's evidence.

Continuing, WITNESS said a Planté cell would work as a regulator under certain conditions if they did not want it for storing, but not in the way described in the specification. He had heard it suggested in cross-examination that the cells might be kept in good condition by charging them up to fully bubbling point once a week or so, but did not think once a week was enough. He also heard the suggestions that had been made as to rendering it unnecessary to charge fully by increasing the size of the plate area. It was not a practicable way of overcoming the difficulty. In modern cells the resistance of the cells might be made as small as one pleased by increasing the surface of the cell, and it had been suggested from that that they could charge them with a slight balance of pressure. The resistance, however, was not the important quantity; it was the back pressure of the cells that they had to consider, and the back pressure of the cells went up to 2½ volts; that was so if they charged a cell, however large it might be. As to the Planté cells of 1878 they had a great deal of leakage. The result was that if one increased them one increased the amount of leakage. With regard to the plateau of which they had heard so much, witness said the charging and discharging curves did not correspond, and proceeded to explain it to Mr. Justice Smith as to the possibility of practically using earth-plates. He had tested an earth-plate, which he understood was put in the ground by Mr. Lane Fox in a garden at Teddington. He tested it recently, about four months ago. It was put there about 1884. It was about four feet by six. He put the dynamo straight on to it—short-circuited it, as it were, through the plate—using that as one plate and the water pipes as the other, with 60 volts, at all events, on the earth-plate itself. He got 20 amperes. There were no lamps at all. All the current that the dynamo generated went through the earth-plate. The dynamo was capable of generating a good deal more, but had not the chance. The current was simply dependent on the resistance of the earth-plate. Taking Lane Fox's, specification the earth-plates would have to be of a fabulous size. He did not want to make an absurd statement, but he had calculated from that that the plate would be somewhere between 26 acres and four square miles to take 1,000 amperes—it was really utterly ridiculous—with one volt at each earth-plate. He was aware that the specification referred to the possibility of using gas and water pipes as an advantageous connection with earth. It would not be practicable. The chief difficulty would be that wherever the soil was damp the pipes would be eaten away. It would not be a trifling matter. It was a matter which could be rigidly calculated, and for 1,000 amperes running continuously, day and night, you would eat away about 10 tons of pipes in a year. That 10 tons would not be spread over the whole installation. The total 10 tons would be chiefly concentrated at the damp places. It would therefore, eat the pipes into holes there. Explaining the function of the feeders in the defendants' system, the witness said the difficulty soon came up of the variations of pressure due to the resistance of the mains. To get over the loss of pressure due to the resistance of the mains, the use of feeders for carrying the current in at various points had been adopted. The feeders secured a constant pressure from place to place, as well as from time to time.

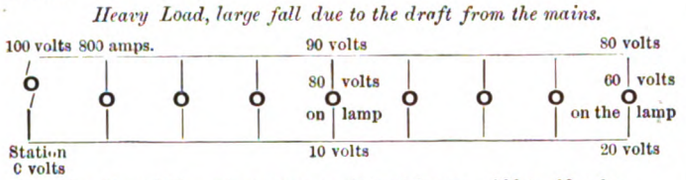
Cross-examined by Mr. MOULTON, Mr. SWINBURNE said any competent electrician reading the specification would know that the earth was being used as a very good conductor. If for any reason he did not want to use the earth he would use another conductor. Supposing there were telegraphs about and he was forbidden to use the earth, he would know that he could use an insulated conductor. He did not think any competent electrician would attempt to make an earth-plate of 26 acres and four square miles; if the competent electrician used an uninsulated conductor, the potential of that conductor would not be substantially zero. It would probably be two or three volts away from zero, and that would eat it through in a very

CASE I.—NO EARTH RETURNS. NO BATTERIES.

Light Load.



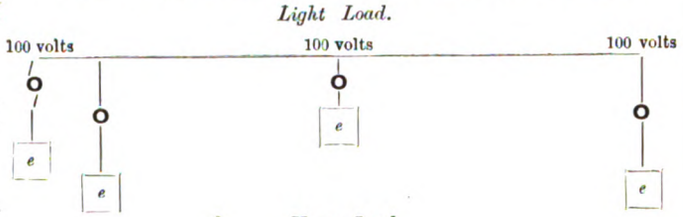
Heavy Load, large fall due to the draft from the mains.



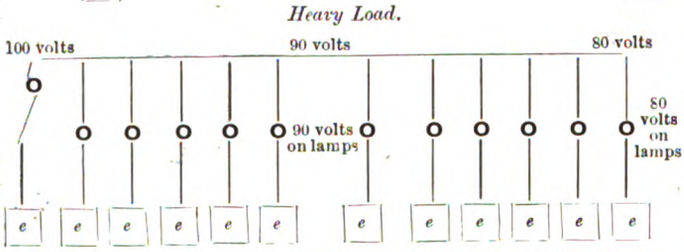
Result variation of pressure on distant lamps—100 to 60 volts.

CASE II.—EARTH RETURNS OF NO RESISTANCE. NO BATTERIES.

Light Load.



Heavy Load.

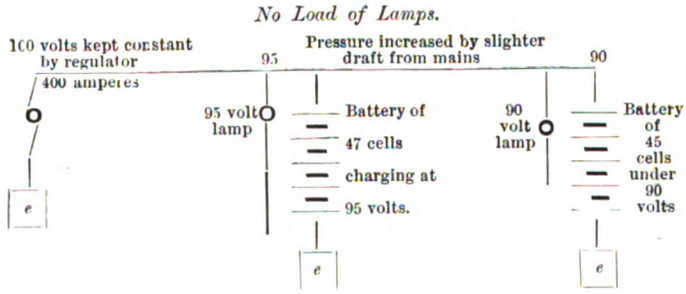


Result variation of pressure on distant lamps halved—100 to 80 volts.

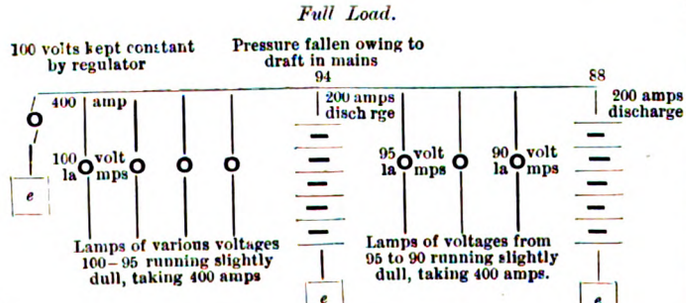
Half the cost of conductors saved.

CASE III.—EARTH RETURNS AND HYPOTHETICAL BATTERIES.

No Load of Lamps.



Full Load.



100 volts kept constant by regulator
Pressure fallen owing to draft in mains

short time. He (witness) assumed that Mr. Lane Fox thought he would save half the drop in the potential by the use of the earth, from his laying such stress in his Claims 1 and 2 upon the returns by earth. Witness having been asked about the preventing of flickering.

Mr. JUSTICE SMITH: Sir Frederick Bramwell always adhered to this, that the automatic part of it would not work. All the witnesses for the defendants adhere to that.

Mr. MOULTON: No, my lord, with regard to stopping the flickering.

Mr. JUSTICE SMITH: They have undoubtedly admitted that there is a regulating power to some extent, if not to a considerable extent, inherent in a secondary battery applied to the main. I think they have admitted that, but they did stand hard and fast to this, that it would not work automatically.

The cross-examination being continued, WITNESS admitted that when one was on the plateau one got a large current through for a very small increase of pressure. Planté's batteries, as made by the original inventor, ran down very quickly by local action, and the coatings peeled off. They kept some charge in for a long time if one kept them fully charged, but if one charged and discharged them constantly they would not. He would not say a Crompton-Howell cell was a Planté. The last portion of the charge was, as far as energy went, largely wasted. It was for the purpose of preventing chemical action in the batteries. It was not necessary to go higher for the electromotive force, but it was necessary to bubble more in the present type of cell than in the Planté in order to be sure of complete conversion of the lead.

TUESDAY, MARCH 15TH.

Mr. JAMES SWINBURNE, recalled and cross-examined by Mr. MOULTON, said that when the battery was on the plateau a change of 1 per cent. would make a considerable current come out of the battery for a short time, and a rise would cause a considerable current to go in also for a very short time.

Re-examined by Mr. FINLAY, WITNESS said the current would last for a few seconds. After a few seconds the current fell to almost nothing. It would not last long enough to be of any effect in regulating in the sense used by Mr. Lane Fox. If Mr. Lane Fox had thought of feeders he would not have filed his application at all.

Mr. H. T. SHILLITOE, examined by Mr. R. W. WALLACE, said he was electrician to the Marquis of Salisbury, and had had charge of the installation at Hatfield House from the first. That was from about the year 1879. The electric current was conveyed to the house by leads hanging on poles insulated by ordinary porcelain insulators. The return was attached to the water-pipe that ran from the saw-mill to the house. The wire was carried from the negative side of the dynamo, twisted round the water-pipe and soldered to it. For some time it worked very well, but it was more or less the whole time in use very erratic, frequently being eaten off near the pipe, and the connection broken entirely. As a remedy they used an insulated return. When they first began they ran something like 20 amperes.

Cross-examined by Mr. MOULTON, WITNESS said that they used an alternating current of high tension, 500 or 600 volts. The shocks from alternating currents were undoubtedly far more severe than from direct currents. He would not like to touch any portion of a system with 800 volts alternating unless it was well insulated. If they had a system insulated all over with 800 volts alternating, and any person touched a bare portion of a conductor, he would receive a still more strong shock.

Mr. DORNER, examined by Mr. FINLAY, said he was an electrical engineer, engaged by Messrs. Siemens Brothers. Since 1866 he had had experience of electric lighting practically. Since 1877 his first experience was putting up the electric light at the Lizard Lighthouse. He was engaged in putting up an installation at Lord Armstrong's house at Craigside in 1878. The dynamo was between a mile and a mile and a half from the house, driven by water. They used about 15 amperes. The voltage was 50. The outgoing conductor was insulated, a bare copper wire on posts. He found in the house a water-pipe going down to a lake, and this he used instead of an earth-plate. He connected by an insulated wire, and soldered it down to the pipe. It did not work. The dynamo did not excite itself. He could get no current from it because the circuit was not complete, and the resistance between the two pipes was so great they would not pass the current through the complete circuit. After that he put another metallic return wire up in the same manner as he put the main wire, and then it worked all right. As an electrical engineer of experience, if he had been working under the specification he would have put two earth-plates in.

Cross-examined by Mr. MOULTON, WITNESS stated that if the two earth plates had not worked he would have put a metallic return.

Prof. A. B. W. KENNEDY, examined by Mr. R. W. WALLACE, said that in the ordinary course of business of the Westminster Electric Light Corporation he had made certain tests of the working of the batteries. The tests were in no way in contemplation of this action. They were the ordinary tests before accepting the batteries on the part of the Company. They were all made in the course of last year. The conditions which had to be fulfilled by that test were that the battery should be previously fully charged, and should then discharge 400 amperes at 90 amperes per hour, and then should fully discharge itself. The conclusions he drew from the whole curve handed in were first that the charging had to go on on a very much higher level than the discharging necessarily; second, that the pressure fell very notably indeed (6 per cent.) during the course of the discharge; the third, that the discharge line was extremely uneven because of certain irregularities in the resistance that the battery was discharging through; the point of interest was that the pressure in the battery followed all the larger irregularities very minutely. Witness then gave some details as to his experience of lamps being switched on and off. A church was suddenly switched off, and the neighbours were very much disturbed and came to worry him. He had the batteries on. The switches were on, but the drop occurred before they knew anything about it—before they could touch the switches—which caused the people to complain that their lights flickered very badly, and he had no doubt they complained quite rightly. He only wished that if an arc lamp was turned off, or on, on his circuit the batteries would prevent any flicker. He had two or three consumers who used large arc lamps for photographic purposes, and the best of his endeavours had not been sufficient to induce them to put them on and off, so as to prevent annoyance to their neighbours. They were large 40 ampere lamps. The batteries did not act as regulators under those circumstances. The batteries were always on.

Mr. JUSTICE SMITH: This gentleman tells me they are always on, and according to this gentleman they regulate a certain amount, but not above a certain amount; that is his evidence. Other gentlemen say they regulate more than this gentleman says they do. First there will be a question what amount of regulation these batteries are able to exercise at all—whether it is appreciable, or of value. I have been sitting day after day hearing this, and we must keep to the points. I have to decide at last, and not wander all over the place. When you switch in a battery on your main do you not do that for the purpose of keeping it constant?—My load increases, and I have to increase the pressure at my station in order to drive current through the mains. If I left the switch where it is I should unduly drive too much current through my batteries, because there is only a certain number of cells, and the increase of pressure depends on the dynamo. If I increase the pressure by opening the throttle valve and letting the engine run away, I might harm the battery by putting through too much, and I switch up one cell to increase the pressure at the station without harming the battery. I can put any amount of pressure through the cells if I drive it hard enough.

Continuing, WITNESS said the use of the battery was to give a current at the time the dynamo was not working. A battery without switches would not have any effect as a regulator The battery would soon be destroyed, and the effect on the lamps, supposing lamps were interposed between the dynamo and the battery when charging or attempting to charge, would be similar. If the batteries had been filled and the dynamo stopped working, and the current was required on the mains from the batteries, the result would be on the lamps. Supposing the battery was only at 100 volts or 102 volts, that would not give sufficient light.

After cross-examination of the WITNESS by Mr. MOULTON and re-examination by Mr. FINLAY,

Mr. BERNARD DRAKE was examined by Mr. FINLAY, and stated that he first began to pay attention to the subject of secondary batteries in 1883. The Paper he read before the British Association in 1886 showed clearly the result of the experiments he had made at the Power Storage Company, namely, that accumulators made of lead must be charged to 2·5 volts per cell to enable the plates to last at all and work. They always charged fully in every house they had lit.

Mr. JUSTICE SMITH: How long has that been going on?—Since 1884, my lord, when I made the discovery that it was necessary. That was the essence of my Paper to the British Association.

Mr. FINLAY: What is the object of the secondary batteries?—As a reservoir, to enable the engineer to stop his engine at night.

Mr. JUSTICE SMITH: Supposing, Mr. Finlay, it be the fact that there is an inherent property of regulation in the battery, and you take the whole thing and use it for another purpose, you cannot help having the regulating effect. Is not that an infringement?

Mr. FINLAY: I submit not, my lord. I shall deal with that. It really, if you think of it, comes to this: the plaintiff is claiming for one quality in a thing that existed before his time.

Mr. JUSTICE SMITH: No; he claims for something which he says he has found out, and which has this inherent quality. Now, can a person take that thing and use it for something else without infringing?

WITNESS was then cross-examined by Mr. MOULTON, and re-examined by Mr. FINLAY.

Mr. FRANK KING was then examined by Mr. R. W. WALLACE, and his evidence consisted almost entirely in description of experiments specially carried out for the purpose of this trial.

WEDNESDAY, MARCH 16TH.

Mr. FRANK KING was recalled, and his cross-examination by the ATTORNEY-GENERAL continued. At the conclusion of the cross-examination Sir HORACE DAVEY pointed out that Prof. Thompson used an edition of 1884 of Sprague, and that the edition in existence in 1878 was the edition of 1875, which did not contain the definition or dictum which was quoted. In the one used it was "'earth,' a name derived from the old mistaken notion that electricity is pumped up from the earth as a great reservoir. Putting to earth and earth connection means a general return circuit which, for economy, is formed through the earth by means of earth-plates buried in moist strata at the various necessary points, but any conductor common to several circuits is technically called earth." That was in the edition of 1884, but the edition of 1875 did not contain the definition of "earth."

Mr. FINLAY then proceeded to sum up the evidence on behalf of the defendant Company. His observations would naturally group themselves round three heads. The first was, the process described in the specification was, they alleged, an unworkable one; secondly, there was no patent for regulation, and, if there were, it would be bad and not the subject-matter of a patent; and the third was that there was no infringement. One would have expected, if the patent really contained within it the valuable invention his learned friends relied upon, it would have been heard of a very great deal sooner. It had only emerged and come before the Courts in the year 1892. No adequate explanation had been given for that delay, and the true reason was that the patent was not worth anything. He submitted that the meaning of the term "the earth," as employed in the specification, was simply a question of the plain ordinary meaning of the

Digitized by Google

English language. All the electricians in the world might come and give evidence as to technical meanings and so forth; but he submitted that nothing would serve his learned friends' purpose beyond demonstration, that to an electrician in the year 1878 a direction to use the soil of the earth would mean a direction to use something else. Unless his learned friends could establish that they had nothing. That, of course, was perfectly impossible. It would be contradicting the plain meaning of the words of a document which the Court had to construe.

Mr. JUSTICE SMITH: I agree with you. I have said so dozens of times in these fourteen days, but it has gone on. However, never mind, we are getting on now.

Mr. FINLAY: I submit, after all the flood of learning we have had on this point, it comes back to the meaning of the English language, and I defy my learned friends to make out that it means anything but what it says.

Mr. JUSTICE SMITH: Suppose you get as far as this. I am to read it as soil of the earth; how do you say I am to show it is unworkable? What do you measure unworkable by? At one gentleman's house it was got back with 15 amperes. That is sufficient for them.

Continuing, Mr. FINLAY said that the evidence as to Holyhead was a statement in answer to a question from his lordship as to what the witness had heard. The witness had never seen it, and knew nothing beyond what he said there. He (Mr. Finlay) did not think any cross-examination was directed to that point. The letterpress of the specification showed at page 4, line 55: "The cells should have a very large conducting surface, and there should be several batteries connected up at various points of the mains, so that by increasing the E.M.F."—and so on. It showed the patentee was describing a large system, and figure 3, which showed 328 lamps, was only a small portion, just enough to illustrate the sort of thing the patentee was at work upon. He submitted that the patent was directed to a large system of electric lighting for a district, with batteries scattered about at different points of the district, and with a very large number of lamps, 328 being shown in the small sample which was given in figure 3. Now, if that were so, the Holyhead instance, assuming it to have been proved, would really have no application. It was one case of arc lighting with a certain number of amperes. The evidence had clearly established that the earth would not work with a system of incandescent lighting, on account of the enormous size of earth-plates required. It was very instructive to recollect how this was dealt with by Prof. Perry. Prof. Perry read the patent as applying to the earth, and said there was no difficulty about the earth plates, and indicated the panelling of the court as about half the size of the limit. When Mr. Lane Fox came into the box, having had the opportunity of reflection, he had to say he entirely disagreed with Prof. Perry. He submitted after that it was impossible for his learned friend to sustain his contention, and that alone really made an end of the case. The defendant Company's witnesses had proved that not one instance of the application of earth returns to incandescent lighting could be produced. That spoke volumes, and ought to be absolutely conclusive on the point. He would now pass on to the next point, on which he submitted that the patent was proved to be unworkable. His side said that one cannot work it without the arrangement of switches and extra cells, because if one did the lamps would be destroyed. His learned friends stopped at the plateau in charging, they only got their cells half full. They could not get the benefit of the plateau in returning unless they charged their cells full, because the plateau from "A" to "B" in returning was the level at which the discharge kept when the cells had not been filled full. How did his learned friends try to meet the necessity of switches and extra cells? Here, again, his opponents had two cases mutually destructive. At one part of the case, his learned friends' view was that the switches were unnecessary, and that people did not require all this switching in and out and extra cells if only large plates were used, and, as they put it, kept upon the plateau. Then further on in the case, when the other side was pressed, with his evidence, questions were put indicating their view was that any competent workman would have known about switches. Switches, his friends said, were not a novelty, and any competent workman would have seen they were necessary. His learned friends had liberty to put forward those two cases; but then he was at liberty to point out that they are mutually antagonistic and destructive. About the fifth day of the case a number of questions were put to Sir Frederick Bramwell, and probably to other witnesses, indicating that his learned friends' case was that they were for the relapse, so to say, in secondary batteries, owing to its having been forgotten that Planté's form was really the best form of all. Now he claimed to have destroyed that idea altogether by his evidence. He submitted, conclusively to the Court, that the failure that took place was due to the non-realisation that it was necessary to charge the cells fully, and not to the use of pasted cells. His learned friends said, "You do not want this arrangement of switches at all; make your cells large enough; make the area of plates in your secondary batteries large enough; have either your plates of very large size, or a great many plates of small size, so that you have a very large area of plates in the cell." In the first place, there was no direction for that in the specification at all. It had been clearly pointed out that the internal resistance of the cell was an insignificant fraction as compared with the back E.M.F., caused by the chemical action which took place. That one did not get rid of by large cells at all. The speculation, for it was really nothing else, had never been carried into practice; nobody pretends to have solved the difficulty by having batteries of the size shadowed forth, or anything approaching it—it was a mere speculation—and he submitted that that speculation had been absolutely destroyed by the practical evidence given on this part of the case. Where, again, did they find the direction to keep on the plateau?

Mr. JUSTICE SMITH: What they say against you there is that Planté says you are to go to bubbling; the bubbling goes up to "B," and therefore you are not to go above "B." That is their case put shortly.

Mr. FINLAY, continuing, submitted that the other side did not in any way incorporate the direction into the specification. With regard to his contention that the thing was unworkable for want of switches and extra cells, and the answers of his learned friend that these were not really wanted, he would point out that in practice, with two exceptions, which really, when they were examined, came to nothing, in every case which was claimed as being an illustration of the use of the patent, switches and extra cells had been used. He would not deal with the expense of the enlargement of the plates. He had pointed out, as a matter of fact, that the increase in the size would not effect the object desired. As to using the cells in the way the other side said they should be used, would destroy the cells. On that point he had a very strong case. His side had given, not merely experiments, but the results of experience of actual working. Experiments were most valuable if you could be satisfied about all the conditions; but the result of experience in actual working was far more valuable than experiments, because that experience was not acquired with a view to the particular case. His side had given this body of practical men to show that to work the cells in the way the plaintiff said they should be worked to carry out the specification, would destroy the plates and cause the buckling to which reference had been made so often in the case. His learned friend's alternative case was this:—"Assuming that the Court thinks that all our evidence that it could be done by the use of the plateau and the large cells and watching the lamps to see whether things seemed to be getting critical with it owing to the rise in voltage—assuming that is to be thrown overboard, we have an alternative case, and say any competent workman in 1878 would have known that and put in switches, and that is a merely mechanical arrangement which would be supplied by the mechanical workman who read this specification in the year 1878." That was making a very large draft upon the ability of the workman. How could his learned friend, having regard to the language of the specification, and having regard to the passage in the patent of the same year, three days afterwards, 4,043, assert that a hypothetical workman would think of switches? The paragraph which was incorporated in the final of 3,988, was followed in 4,043 by a paragraph for the use of commutators, which was not incorporated. "Or I sometimes supply each of these reservoir batteries with commutators, and with the means of working them so that it will not be necessary to increase the E.M.F." The inference was irresistible that, in the paragraph that preceded, the action was to be automatic. He submitted that this specification did not show a patent for regulating at all. It was a patent merely for the use of secondary batteries as reservoirs of the electrical energy in combination with the system of distribution described. There was not in the specification a single word about regulating except by the regulator, which had since been disclaimed. On this point his friends were in a dilemma. If regulation was to be found in the final, it was a departure from the provisional, not in a matter of detail, but on the one point which was now claimed as the point of the patent. If, on the other hand, the final was in conformity with the provisional, then regulation was not there.

Mr. JUSTICE SMITH: Supposing the provisional said: "I claim for the secondary batteries that they keep up constancy," and then that the final had said: "I claim for the secondary batteries that they keep up constancy." Why am I to read that as not to mean regulation? Keeping constant means regulating. Leaving out the other regulator altogether for the moment, and supposing it stood like that alone, why ought I not to read it so when there is some evidence—when I say "some evidence" I mean a considerable body of evidence—that it had a regulating power? Why am I to read it that it does not mean to regulate? You have got a better point now, which I have never seen until this moment, namely, that they never claimed the secondary battery as being regulators at all in the provisional.

Mr. FINLAY: Yes.

Mr. JUSTICE SMITH: I see the point.

Continuing, Mr. FINLAY said the secondary batteries were introduced, and the description of the regulator was given in detail. That was the regulation which was said to be necessary—by the regulator. Then, when they came to the final disclaimer, he submitted that the attempt was being made to employ the word "regulating," which was contained at the commencement of the specification as disclaimed, in a perfectly different sense from that in which it was used at the commencement of the original.

Mr. JUSTICE SMITH: I agree with you there. I am reading now at line 44, on page 5, "And I declare that I claim as my improvements"—it originally ran thus—"in obtaining light by electricity, and in conveying, distributing, measuring, and regulating"—that "regulating," as it originally stood, I have no moral doubt referred to the electrometer. I have not the slightest doubt about that. It is a matter of construction.

Mr. FINLAY: I submit so, my lord.

Mr, JUSTICE SMITH: But then the difficulty I have, if I may say so, is this. Let me put my point to you. A man claims "A," and he claims "B." He claims "B" for regulating as well as "A," but he does not think that it will avail him so much as "A," but it turns out afterwards that "B" will regulate. Why cannot he disclaim "A"?

Mr. FINLAY: But he has not claimed "B."

Mr. JUSTICE SMITH: That begs the whole point as to what is the meaning of "constant."

Mr. FINLAY: Yes, but at the same time your lordship will see this. "Constant" of course, is a word which does not necessarily at all relate to counteracting momentary flickers. The meaning of keeping the force in the mains constant may be that you want to have the same amount of force available for all times, so that you can keep up your voltage to the required point, however great the load which the voltage has to carry may be.

Mr. JUSTICE SMITH: The evidence of a very eminent man is: "I think that secondary batteries would tend largely to correct the rise and fall of voltage when lamps were turned on and off."

Mr. FINLAY: I accept that fully.

Digitized by Google

Mr. JUSTICE SMITH: How can you say afterwards that it is not so? I mean, all the gentlemen minimise it as much as they can, but they all have to come up to the scratch at last when they are cross-examined as to this.

Mr. FINLAY: Yes, my lord, I am ready to deal with it on the footing of what Sir Frederick Bramwell said, but what I point out to your lordship is this. What he says is: "They would have that tendency, but as a matter of fact we do not use them for that purpose."

Mr. JUSTICE SMITH: That is the other point on the infringement question, and I agree that you have a large body of evidence to show this. You have this proved, that these secondary batteries are not universally used. In a large number of installations they are not used, and in others they are, and I think, if I may say so, the preponderance of evidence is that they are not used for regulating purposes at all, but they are used for storage purposes, *de facto*, by people of competence. Does not the evidence come to this, that the plaintiff has put his case too high when he says that it will have such a controlling effect as the specification would lead me to believe, but it still has a controlling effect?

Mr. FINLAY: I submit it comes to more than that, namely, that they have put their case so high because it is only by putting their case so high that they could hope to make it applicable to us, because we do not use gas engines.

Mr. JUSTICE SMITH: You are now arguing the point that even if this claims a regulating process it does not regulate at all.

Mr. FINLAY: Yes.

Mr. JUSTICE SMITH: I am against you there.

Mr. FINLAY: Oh, I do not say that it does not regulate at all. I did not intend to put it so high as that.

Copious extracts were then read from evidence, and cases were cited in support of the contention that secondary batteries having inherently a moderate regulating effect, their power of regulation could not be claimed in a patent. It was perhaps a great "discovery," but not an "invention."

FRIDAY, MARCH 18TH.

The ATTORNEY-GENERAL, in closing the case, said that counsel who came into these cases cram up the alphabet before the case begins. The learned Judge was not in that position; and he hoped it would some day be more the practice to have assessors sitting with the Judge, because he was sure that time would be saved by not having to go through what he might call the alphabet of any particular science. The case was boiled down by his learned friend Mr. Finlay's most able speech to three points. One, that there is disconformity between the provisional and complete specifications; next, the patent is unworkable, meaning thereby that the specification is not sufficient; and third, that there is no infringement. As to any one of these points, he admitted if they could be made out in substance and not mere form, they were objections which would be fatal to this action. Sir Horace Davey said the main ground of infringement was that these batteries acting as regulators was not in the claim. He meant that there was disconformity between the provisional and complete, which was not exactly the same proposition of law, but it did to a certain extent cover the same ground. There were one or two general propositions. The first is that it is established in law that the thing does not cease to be an infringement because it is an improvement; secondly, that a patentee is not bound to write out, and ought not to write out, that which will occur to persons ordinarily skilled in the particular science to which the patent is addressed. The question is not what the infringer meant to do, not the object with which he has taken the so-called invention, but whether he has taken it. There is no authority or vestige of authority which suggests that if in the provisional specification you have described in general terms what you propose to do, that there is any disconformity because you do not point out the advantages either in the provisional or in the complete specification. The function of the provisional specification is to point out what the invention is, to identify the ambit of the invention. When the nature of an invention has been described in the provisional specification in the way which has been mentioned, if something were found out during the six months to make the invention work better, or with respect to the mode in which the operation may be performed—a thing which is very likely to happen when in carrying out his invention the inventor finds that some particular bit will not work so smoothly as he expected, and it is necessary to add a little supplement to it—still the nature of his invention remains the same, and it is no objection that in the complete specification which comes afterwards, the invention or application is described more particularly and in more detail, or even if it be shown that there has been more discovery made, and so as to make the invention which he has described in the provisional specification really workable. His learned friends had endeavoured in their argument and by their questions to cut down Mr. Lane Fox's regulation to nothing but the flicker when the gas-engine was running. From the point of view of utility it would be sufficient to admit that, but when he came to the question of infringement and of user, that the great discovery of Mr. Lane Fox was this: that you can have a constant pressure while you are discharging the batteries, of course the generator running all the time, and that the importance of the invention is that although you are generating more current than you want at the time the lamps are on, you store it up in your batteries to be ready to be used at the same pressure when you have more lamps—that is to say, less current than you want, or when the current is coming partly from the generators and partly from the batteries. That is what regulation means in this patent.

Mr. JUSTICE SMITH: What they say is, you claimed in the provisional for battery as a reservoir? And you claim in the complete battery as a regulator; that is what they say. You say it makes no difference.

The ATTORNEY-GENERAL: And more than that, my lord, I say I did not put in the provisional specification batteries as a reservoir only. In line 45, the E.M.F. in the mains is to be kept constant; and at line 36, a number of Planté's batteries will serve as a conductor of electricity. If the collocation and position of those things involves this necessary incident that out from the reservoirs come amperes when required, and into the reservoirs come amperes when required, that is what is pointed out in the provisional specification. He then passed to the question of sufficiency. It involved two important questions—that it is bad, because soil-returns are to be considered as the soil mode of return; secondly, it is bad because you do not find any mention of switches in the specification. With reference to devices to secure constancy of the electric light, it is admitted that Mr. Lane Fox enunciates that proposition for the first time. That is not enough. He must tell the public how to do it; and the question is, upon this matter, what was the method he devised for telling the public how to do it? You may require to run your generator at a time when your lamps that are on will require more current than your generator will ordinarily give out, and, accordingly, you must have the means,—and, he used this word advisedly, automatically. He would point out presently the defendants use it automatically unquestionably, whether they supplement it or improve it for certain purposes by the manual action of switching in boxes, but they use it for periods of hours, on the evidence of Mr. Miller, automatically. He cared not whether it be more corrected when they used switches than without switches; the point he took upon this is that the constancy in the mains depends upon the combination of a current from the generator and a current from the batteries, the batteries being so coupled up (that is the feature) between the return wire and the main, the main and the earth, that it must have the function which they were considering when enunciating a principle of which electricians had never even dreamed, and it was no exaggeration. He cross-examined one of their witnesses—Dr. Hopkinson—as to the number of distinguished men who gave evidence before the Electric Light Commission in 1889, while Mr. Lane Fox's document was a secret paper—a concealed paper—and there were men like Sir William Thomson (the present Lord Kelvin), Sir William Siemens, Dr. Hopkinson, and many other distinguished gentlemen, not one of them regarded the sub-division of the electric light so that a constant current could be maintained as within the range of practical electricity. Then to say it is to be treated either as a matter of common knowledge that you could put together as Planté batteries or electric generators, or that the function which they are to perform, in itself new—in itself absolutely new—the function that these secondary batteries are to control the E.M.F. in two ways—they, in the first place, take up excess voltage; and, in the second place, take up excess amperage, that they in the first place give off additional voltage if required; and, in the second place, they give off additional amperage—that is enunciated on both points of view by Mr. Lane Fox in plain and simple language. He submitted that that is not to be treated as not enunciating an invention of the greatest novelty, however much it may be improved now, is not doing justice to Mr. Lane Fox, and is to construe this specification according to the criticism of people who have absolutely done nothing to improve Mr. Lane Fox's system except add a discharging switch.

On passing to the construction of the specification in regard to earth, Mr. JUSTICE SMITH said: The first question is, What does "the earth" mean in this context?

The ATTORNEY-GENERAL: Certainly, the first question is, "What does the earth mean in this context?" "The earth" means in this context, and ought to be taken to mean by everybody who read this specification in the light of the then knowledge, any return which is available for distributing light. He submitted that it does mean in fact, and would be taken to mean for the purpose of patent law, any return which fulfils the condition of the return contemplated by Mr. Lane Fox.

Mr. JUSTICE SMITH: What do you say to this proposition: supposing Mr. Lane Fox's idea was to have an incandescent lamp, and he certainly had the idea of having 400 or 500 lamps at the least; and suppose it turns out that the earth-return for 400 or 500 lamps was imperfect, what then?

The ATTORNEY-GENERAL: If so, this patent is perfectly good, my lord; and I will tell your lordship why, because the question you have to consider is whether or not the particular method of return he contemplated is "of the pith and marrow of the invention."

Mr. JUSTICE SMITH: That is another point. Let me see if we agree in the law. Suppose it is the pith and marrow that it should be the soil?

The ATTORNEY-GENERAL: Then, my lord, I should be wrong, wrong completely; if it is "the pith and marrow," I am done altogether.

Mr. JUSTICE SMITH: You would not say if it would return 10 lamps and he claims 400, that it would do?

The ATTORNEY-GENERAL: No witness has suggested that the increase of the number of lamps would create the slightest difficulty in carrying out Mr. Lane Fox's invention, unless they construe it that it must be soil and nothing else. My learned friend will see that I am right upon this.

Mr. JUSTICE SMITH: I agree with you, if you are entitled to use any return other than soil, you can get it back easily.

The case of Brett was then cited by the ATTORNEY-GENERAL. This was a patent by Cooke and Wheatstone, for electrical alarums worked by currents transmitted through metallic circuits. After the date of the patent (1837) the use of earth as a return was discovered. The infringer used earth. It was insisted that no infringement had been made by the defendants, or, indeed, could be made, as long as the circuit they used was not metallic throughout, but to a substantial extent non-metallic. "The circuit used by the defendant was metallic in all that part which operates in giving signals, and in all the parts to which the plaintiff's alleged improvements applied, and it was no condition necessary to the existence of the improvements that the circuit should be metallic in any other part than that which contains the coils and operates on the needles." When the electricians come and stand in this Court and bring the power of their combined in-

Digitized by Google

telligence to endeavour to show that Mr. Lane Fox's patent is bad—they have been brought up to the mark to do that, and give their view, of course, with perfect candour, though sometimes their view is a little warped—there is not one mind which ventures to say from practical electrical working the system of distribution is altered one whit by leaving out soil, and putting in either insulated or uninsulated return. Of course the nearest parallel would be an uninsulated return of copper wire. These complications of charging which they have introduced, in order to try and get out of the most obvious infringement—charging high—is simply and solely due to the fact that they, for the purpose of economy, choose to have a larger number of cells than they need, and therefore they must have a shifting charging switch as well as a shifting discharging switch. If they had not more than 50 cells they would never want anything but a discharging switch. These complications Mr. Crompton has introduced, on which they say the system can only be worked, namely, by having a charging as well as a discharging switch; but it is simply and solely due to the fact that they wished to charge, for the purpose of economy, a larger number of cells than they need. The contention is twofold—that you cannot carry out Lane Fox without a discharging switch, and that you cannot carry out Lane Fox as the defendants do without a charging switch. On the question of sufficiency of specification, he submitted that the discharging switch was the only important one. On this question of sufficiency he was taking Lane Fox pure and simple. [*The model* was put before his lordship.*] The position, "D," Dr. Hopkinson admitted is Lane Fox pure and simple during the process of charging. "E" is Lane Fox pure and simple during the process of discharging. He was not dealing with the question of the balance in between. That comes at a later point. Now, he would assume for the moment that the man was going to work out Lane Fox pure and simple; that he has got no movable charging switch, and he would take any number of cells—it does not matter whether they took 51, 52, or 53. He asked his lordship kindly to put the discharging switch at 50, and his lordship might put the charging switch "X" at the same point, or higher. That is the position of things in which Dr. Hopkinson admits that as long as it is used in that position it is Lane Fox pure and simple. Now what happens? What is the problem that an ordinary electrician has got to solve? Of course, there must be a switch to get into the main.

Mr. JUSTICE SMITH: How do you mean there must be a switch to get into the main?

The ATTORNEY-GENERAL: The boxes must be connected with the mains by means of a switch. The direction of the specification is that they are to be coupled up between the mains and the earth. When he used the word "switch" he merely meant a connection. He was assuming that the gentleman starts having nothing but the Lane Fox specification before him, with the switch at 50. [He then read the description† provided with the model, and a passage from the specification.] Dr. Hopkinson admitted that as long as they had got the two switches opposite one another, they had got the absolute letter of the thing that Mr. Lane Fox describes. Why was the discharging switch "Y" to be shifted down? It was because the E.M.F. in the secondary batteries was rising. He would for a moment consider the three directions Mr. Lane Fox had given, and the common electrical knowledge at that time. First, they had to charge the batteries, and accordingly connected the top battery with the main, and proceeded to charge, raising the E.M.F., as Mr. Lane Fox directed them to do, in the mains. The other direction he gave was that the pressure in the lamp main was to be constant. He asserted as part of his argument, and his strongest argument in this case, that the only thing that was necessary to work Lane Fox according to the best possible way was to put in a movable discharging switch, in order to do the very thing which he told them to do—to keep the E.M.F. in the mains constant, and to vary the number of cells according to the E.M.F. in the mains. Prof. Forbes said it was everyday work in all electrical work to attach the wire to different points of a battery, so as to use more or less cells. It was done every day in telegraphy. The other condition of things which was said to be new is, that if you desire to charge very highly you must have a switch to enable you to move the switch back for the purpose of high charging. It had nothing in the world to do with Lane Fox. It had not the slightest relation to Lane Fox. It was never known at that time, and it is the subject of a subsequent invention, and had nothing in the world to do with the regulating, with the storage, with the kind of reservoir, or anything of the kind. The whole of this question of charging batteries to excess had been introduced into this case for the purpose of suggesting, that at the outside, what was an improvement of Mr. Lane Fox's was that which can be used to show that Lane Fox had made no invention. The whole point of this was that in 1884 it was discoved by Mr. Drake or Mr. King that it was desirable, from the point of view of health, to keep batteries healthy by charging very highly, as distinguished from charging as people believed before. Nobody suggested that they act differently when they are in a condition of health. They provided that, instead of charging only 50 cells, they should be able to charge whatever the proper number may be by moving the switch back, and it has not the slightest relation to the question of how Lane Fox acts either as a reservoir or a kind of reservoir or a regulator. Mr. Drake made the discovery of charging these cells, and he does not suggest that there was any difficulty in applying it. The point is this—that at the time of Lane Fox they thought that it was prudent to charge low, and in the time of Drake and Gorham they thought it prudent to charge high, and that extra charging switch is simply inserted in that Kensington installation because they wanted to be able to have a larger number of cells, and so reduce the voltage, instead of having a larger number of batteries standing side by side. Did his learned friend suggest that an improved method of charging, whereby they keep the cells healthy in other conditions using Lane Fox, would not be an infringement? He said there is not a vestige of an authority for that contention in the books.

Mr. JUSTICE SMITH: Taking what you are saying about keeping it healthy, they say you must charge up to 125; but they say the result will be to blow your lamps out, and it is no good doing it at that; and they say that you cannot do without some switching arrangement.

The ATTORNEY-GENERAL: Will your lordship kindly take the model before you, and will your lordship suppose that a man working Lane Fox thought it prudent for the sake of health to work up to 125, what has he got to do? It makes no difference for this purpose whether it is 50 or 56 cells.

Mr. JUSTICE SMITH: I quite agree with what Lord Herschell said with reference to the law on this subject, and I must go back to 1878. I am going to make this distribution; but how many lamps am I to blow to pieces before I find it out?

The ATTORNEY-GENERAL: You will not blow one lamp to pieces, my lord.

Mr. JUSTICE SMITH: I do not want to trouble you about the infringement, because, if you are right on the other points, I can find infringement very easily.

The ATTORNEY-GENERAL: He takes 50 cells or any number you like—I may as well take 50. He charges those cells, and finds out, following Lane Fox's directions, that he ought to raise the E.M.F. to 125 in order to charge those properly. The voltage in the secondary battery is rising in consequence of the extra pressure in order to charge. What has the man who watches the batteries to do? He knows from his primary battery that if you have too many cells discharging you will get a higher voltage. He is told by Lane Fox that the number of cells in the batteries is to depend on the E.M.F., and he is told that the E.M.F. is to be kept as near constant as possible. Five witnesses of experience have told your lordship that it was common knowledge to add that discharging switch; and, my lord, I say there is no witness who suggests that it was not common knowledge. Why is this man to shut his eyes to everything that Planté had told him? Now, the competent electrician in the year 1878 knows this—that if he keeps the voltage going out into his lamps constant, of course he will not break his lamps down. The competent electrician knows that the effective voltage comes off on the discharge of either the primary battery or the secondary battery, and yet it being common knowledge, known every day, how to reduce the voltage coming out from an accumulation of cells, by cutting off some of the cells, you are to be told that the patent is to be bad because the patentee has not repeated that common knowledge. In conclusion, the Attorney-General said that in this case there was a a very large and powerful combination against Mr. Lane Fox. One Company, and not by any means an unimportant Company—namely, the Swan and Edison Company—paid him a royalty in respect of this very patent. He was not there to say one word in favour of Mr. Lane Fox apart from this invention. Attempts were made to say that he was a very young man, attempts were made to suggest that he was only a dreamer, and it was suggested that vague generalities were all that he indulged in. The strongest testimony to the merit of Mr. Lane Fox's case may be summed up in two sentences, that, whether there were installations without secondary batteries—which he had no doubt there were, perhaps by the hundred—or not, hundreds and thousands of installations in this country have been erected and set up, and are still working, in which the position of these secondary batteries and their relation to the generators is identically the same as in Mr. Lane Fox's specification, written in the year 1878.

[THE JUDGMENT WAS RESERVED.]

* *The Electrician*, March 18, p. 518.
† *The Electrician*, March 18, p. 519.

On Saturday last the case of RICE *v.* EWING, Managing Director of the Archer Pipe Company, came before Mr. Commissioner Kerr, in the City of London Court. This was an action in which the plaintiffs, Rice Brothers, of 1, St. Swithin's-lane, London, E.C., applied that the defendant, Mr. R. Ewing, of Avenue Mansions, Shaftesbury-avenue, W.C., should be committed to Holloway Gaol for the non-payment of £10. 18s. 1d. due. Mr. Commissioner Kerr having asked the position of the Company and the value of its shares, plaintiffs replied that the Company was a flourishing one, and that the defendant held 1,885 of the shares. Mr. Commissioner Kerr made an order for the defendant's committal for ten days.

Changes in the Conductivity of Water when in Contact with Glass.—It has been long known, says *Nature*, that glass is attacked and dissolved in small quantities by ordinary water. This dissolving process Herr Pfeiffer has recently sought to prove and measure by change in the electric conductivity of the water (*Ann. der Physik*). He measured the increase of conductivity undergone by 1 cubic centimetre of pure water when it has been in contact for one hour with one square centimetre of glass surface, and concluded that the amount of glass dissolved at 20°C. was 1 to 2 millionths of a milligram. He found, too, that with the temperature rising arithmetically, the growth of solubility is considerably more rapid than that of a geometrical series; that the increase of conductivity of the water for a given kind of glass under like conditions is a characteristic constant; and that later, when a certain quantity of alkali is dissolved, further action involves a dissolving also of silicic acid, and the salts then formed may cause a decrease of conducting power.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March* 11, 1892.

The Incandescent Lamp Trade.—The important suit of the Edison Company against the United States Electric Light Company, which was decided by Judge Wallace last year, and which was appealed against by the defendant, has not yet come for decision in the higher Court. It is not at all likely that the case will be reached before July, and perhaps not until next October. One of the Judges of the higher Court has declined to sit in this case, as he has interests that prevent his rendering an unprejudiced decision. It is therefore necessary for the United States Senate to confirm the appointment of a substitute; and owing to the serious illness of the Chairman of the Judiciary Committee of the Senate, no Judge has yet been recommended for the position. In the meantime, the 10 or 12 incandescent lamp companies are turning out as many lamps each day as ever, although it may be said that very few if any of them are making any efforts to increase their facilities for the manufacture of lamps pending the decision in the higher Court. A careful estimate of the daily lamp production of all the companies in this country, made by the president of one of these concerns, places it at 27,000 per day. About one-third of this production is credited to the Edison Company, about one-sixth to the Thomson-Houston; and it is thought that the average price received is very close to 40 cents per lamp. This is based upon the fact that the Edison lamps are sold to supply companies at 36 cents, and to Edison central stations for 32 cents, while the average price for which nearly all of the other companies sell their lamps is not far from 44 cents. The smaller companies say that they are able to compete with the Edison lamps very effectually, even when their prices are 10 cents per lamp higher than those of the Edison Company, since it is said that although the initial efficiency of the Edison lamp is high, its average efficiency is not nearly so high as that of the other companies. Those who are now manufacturing lamps under other than Edison patents do not feel very seriously disturbed, since it is thought that even should the higher Court render a decision against the rivals of the Edison Company that company would not care to summarily suppress the smaller concerns and assume the work of turning out the entire production of the market, as this would necessitate the establishment of a very large plant, which could, at best, be kept in service for only that length of time which the fundamental patent in question still has to run.

German Competition.—Considerable discussion has been started the past week by the report that the German manufacturing firm of Siemens and Halske was about to establish in Chicago, on a very large scale, a plant for the manufacture of electrical machinery and electrical appliances generally. The report is given out on good authority, and, indeed, a company has already been incorporated to undertake the business. It seems to be the general opinion that the new company will be a formidable competitor of the largest of the American manufacturing concerns. The rumour, which, however, does not seem to have gained much credence, is to the effect that Siemens and Halske intend to form a combination with the Westinghouse Company, and to enter into direct competition with the Thomson-Houston-Edison Consolidated Company. It is thought that there is a good field for a new company of this kind, but that it must manufacture American apparatus instead of attempting to introduce German apparatus into use.

The Telephone Monopoly.—The position of the American Bell Telephone Company and its ability to control the telephone business after the expiration of its fundamental patents was recently very thoroughly discussed by Herbert Laws Webb in one of the monthly magazines. Mr. Webb takes a very sensible view of the case, and maintains that while the fundamental patent was at one time the main resource of the company it has long since ceased to be such, and that the system which the company has built up and the hundreds of patents it now controls, as well as the immense amount of capital it has invested in overhead and underground lines, will be sufficient to make it next to impossible for any competing company, especially in large cities, to gain any considerable foothold. This is a view of the case which the general public does not appear to have fully considered; it has been carried away by the argument that since the fundamental patent was the one which gave the company its monopoly the expiration of that patent would throw the telephone business open to the public, and that then an efficient and satisfactory service would be obtained at a small fraction of the cost which every telephone user is compelled to pay at present.

CORRESPONDENCE.

OIL AS AN INSULATOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The use of oil as an insulator has been recently brought before our notice by the charming experiments of Mr. N. Tesla, and the important Paper of Mr. Hughes (read before the Inst.E.E., March 10, 1892).

As I have had some experience of the behaviour of resin oil, may I be allowed to give a brief summary of some of the ways in which it has been used in our laboratory here? In Fig. 1 is shown a Leyden jar, arranged in a bath of oil. A A and B B are the inner and outer coatings of the jar. The outer vessel C C, and the jar are filled with oil up to E. The jar is supported on cotton wool, saturated with oil. D F are two rods of metal, held in position by a cross piece of ebonite; these can be lifted out of contact with the coatings of the jar by the ebonite handle G. To charge the jar D F is let down till it touches the coatings; after the jar is charged, it is lifted out of contact; when the jar is to be discharged the rods are again lowered to touch the coatings. In Fig. 2 is shown a ful-

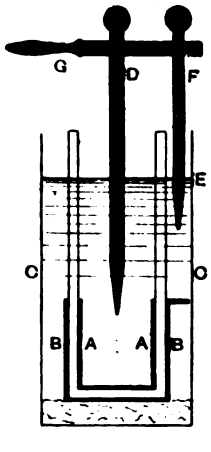

FIG. 1.

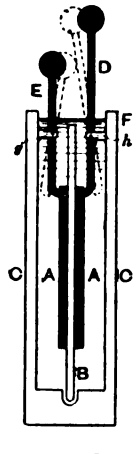

FIG. 2.

minating plane B, also placed in a bath of oil C C. It is filled up to F. A A are the opposed coatings of the plane. D E are two levers whereby the plane is charged and discharged; they move about points at g and h, so that after charging they can be put out of contact with the coatings of the plane. The levers are moved either by silk threads or by an ebonite rod. The resin oil used was supplied to me by Messrs. Elwell-Parker and Co., of accumulator fame; it has been in constant use for three years.

On the dampest days the jar or plane keep their charge well; after ten hours the spark is reduced to about half its original length. Long after the time I have mentioned, the plane will fire a blasting detonator. I have also used oil in a large battery of very small cells used to charge the needle of the quadrant electrometer of Lord Kelvin.—Yours, &c.,

FREDERICK J. SMITH.

Millard Laboratory, Oxford, March 17, 1892.

SOME EXPERIMENTAL INVESTIGATIONS OF ALTERNATE CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the authorised abstract of the discussion published in your last week's issue, I am represented as having said precisely the opposite of what the transcript of the shorthand writer's notes correctly reports me to have said. I remarked that in two transformers, both giving 95 per cent. efficiency at full load, and having the iron to copper losses as 3 to 1 and 1 to 3 when so loaded, the 24-hour efficiency taken on a central-station midwinter curve, similar to that of the Kensington and Knightsbridge Company, comes out at 76·3 per cent. and 87·9 per cent. respectively; thus showing the effect produced by varying the iron and copper losses, even when the sum of the two at full load remains the same. I have not worked out the efficiencies for the summer load, and am therefore unable to give the mean for the year; but it will be readily seen that taken over twelve months, with the lowering of both efficiencies, there will be manifested a still greater advantage on the side of the transformer having the greater copper loss.

I take this opportunity of protesting against the present custom of publishing a scrappy report of the Institution proceedings as an "authorised" abstract. It has always been most unsatisfactory.—Yours, &c., W. B. ESSON.

March 22, 1892.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892.

The tenth annual edition of the above well-known annual is now ready, price 7s. 6d.; post free, in the United Kingdom, 8s. 3d.; abroad (with the exception of a few countries), post free, 8s. 10d.

The edition consists of between 900 and 1,000 pages, and special care has been taken to make the Directorial division of the book, which has been considerably extended, thoroughly accurate and reliable. In this respect no possible comparison can be made with any similar publication.

To the Handbook division has been added several features which will be found of service to the Electrical and Allied Trades. The Digest of the Law of Electric Lighting has been thoroughly revised and brought up to date, and the most recent Board of Trade Regulations are also included. The various tables and tabulated statements have been remodelled and amplified; and a new feature is the tabulation of valuable information respecting Electrical Limited Liability Concerns.

An important feature is the space devoted to the officials of Foreign and Colonial Governments who have the superintendence of contracts and the giving of orders for electrical plant and apparatus; and as this has been kindly supplied by the various Government departments, it can be relied upon, as can also the particulars given respecting the Home Government departments.

The profession will find "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK a trustworthy work of reference, and purchasers of plant and apparatus may confidently turn to its pages for the names of all the principal firms supplying their requirements. Nearly every firm of any standing in the Electrical and Allied Trades is represented in its advertisement pages.

A digest of the contents of the book will be sent on application.

TENDERS INVITED.—The Urban Sanitary Authority of Basingstoke invite tenders for lighting the borough by electricity, gas, or otherwise for a term of five years. Tenders to be in by April 30th. Further particulars of the Borough Surveyor, Town Hall, Basingstoke.

——— EXTENSION OF TIME.—The Glasgow Corporation announce an extension of time for sending in tenders for engines and boilers, from the 29th inst. to the 5th prox., at 10 o'clock in the fore-noon.

——— The Lancashire and Yorkshire Railway Company are inviting tenders for stores, which include brass and copper tubing, signal and telegraph fittings, signal and telegraph wires, wire, wire rope, &c. The tenders have to be in by April 4th. Further particulars of Mr. C. W. Bayley, Hunt's Bank, Manchester.

TENDERS INVITED.—Contractors will remember that the tenders for the wiring and fittings for lighting the buildings known as the Railway Clearing House, are to be in by Wednesday, the 30th inst., and that the tenders for providing and erecting engines, dynamos &c., at the central station of the Glasgow Town Council must be sent in by the 29th inst. to Mr. J. D. Marwick, Town Clerk. The tenders advertised for by the Bristol Sanitary Authority for their central station at Temple Back are due this day (Friday).

TENDERS ACCEPTED.—The tender of Messrs. Fowler, Lancaster and Co., of Graham-street, Birmingham, has been accepted for the complete electrical installation at the baths and public offices of the Aston Manor Local Board. The amount of the contract is £1,594, the only other tender being that of Messrs. Verity and Son, of Birmingham, for £1,662. 7s. 6d. Mr. W. A. Davies, of Aston Manor, is the engineer for the work.

——— Mr. J. E. Johnson, of Highcross-street, Leicester, has secured the contract for the erection of refuse destructor buildings, with engine and dynamo house, boiler house, workshop, &c., which is to be erected for the Sanitary Committee of Leicester. The amount of the contract in all is £5,943. 4s.

ELECTRIC LIGHTING CONCESSION.—The town of Castro-Urdiales in Spain is about to grant an electric lighting concession. Offers will be received up to 26th May.

NYIREGYHÁZA.—The Municipality, after considering the advisability of erecting a central station, have decided to leave the financing of the undertaking in the hands of the contractors, and are accordingly prepared to grant a concession for lighting the town by electricity.

APPOINTMENTS VACANT.—The Electric Lighting Committee of the Town Council of the Borough of Nottingham require the services of a resident engineer, who must have had actual practical experience of installation working. Salary commencing at £300 a year. Applications must be sent in to Mr. Sam. Geo. Johnson, town clerk, The Guildhall, Nottingham. Further particulars are given in our advertisement columns.

——— A competent man is required to take charge of the central telegraph office at Accra, on the Gold Coast, where he will be required to act as Director of Telegraphs for six months, during the absence on leave of the permanent director. Terms are set out in our advertisement columns. Applications should be addressed to Mr. W. H. Preece, General Post Office.

MESSRS. C. E. G. GILBERT AND CO.—We are notified that this firm have purchased the business of Messrs. Adams, of Kensington High-street, which will be carried on by Messrs. Gilbert and Co. as their West End branch, the head office and works of the firm remaining as now.

THE MANCHESTER CENTRAL STATION LIGHTING.—The whole of the electric light cables for this large installation were supplied to Messrs. Mather and Platt (the contractors for the work) by the International Okonite Company. Only the best type of vulcanised india-rubber cables has been used; the specification requiring a very high insulation, both for the arc and incandescent systems.

MESSRS. DRAKE AND GORHAM.—This firm have been instructed by the Duke of Montrose to instal the electric light at Buchanan Castle. Messrs. Drake and Gorham will employ in this installation one of Gilkes' turbines, and the mains will be carried partly overhead, and partly on a modified trough system, based on the experiences obtained at Lord Armstrong's installation; the advantage claimed for this system is that it avoids the use of posts.

EXHIBITION AWARDS.—At the Exhibition recently held at Launceston, Tasmania, Messrs. Davey, Paxman and Co. have received the following awards for their engines and boilers:—A special first award for an 8 H.P. single cylinder portable engine, fitted with Paxman's patent automatic expansion gear; a special first award for a 16 H.P. undertype compound engine similarly fitted; a special first award for the "Essex" patent vertical boiler; and another special first award for an improved double cylinder winding and hauling engine. It will be noticed that the above awards are all "specials."

REMOVAL.—The offices of the Monte Video Telephone Company have been removed from 25, Abchurch-lane to 96, Gresham House, E.C.

ELECTRIC LIGHT INSTALLATION AT BOLTON TECHNICAL SCHOOL.—The electric light installation for the Bolton Technical School, which was formally opened on Saturday, March 19th, has been supplied and erected by Messrs. Ernest Scott and Mountain (Limited), of Newcastle-on-Tyne. There are two dynamos of the Tyne compound-wound type, fitted with heavy turned fly-wheels and fast and loose pulleys for generating the current, each machine giving an output of 90 amperes at an E.M.F. of 105 volts, when running at a speed of 900 revolutions per minute. The dynamos are driven by two 14 H.P. nominal Griffin gas engines, which have been supplied by Messrs. Dick, Kerr, and Co., of Kilmarnock.

Digitized by Google

The total installation consists of about 220 16 c.p. incandescent lamps, the lamps being suspended by flexible pendants from the ceilings in the workshops. Where a concentrated light is required at any particular point the lamps are made to raise and lower, this being found a great advantage for weaving. In the lecture theatre arrangements have also been provided so that the current can be utilised for working the magic lanterns or microscopes, or for demonstrating the uses of electricity either as motive power or for chemical purposes. We may mention that the same firm has recently completed a large installation for the lighting of the printing works of the *Bolton Evening News*, and have also lighted up the Rothwell Hosiery Company's mills at Bolton.

THE NATIONAL TELEPHONE COMPANY.—The dinner to the staff of the National Telephone Company will be held this (Friday) evening at Anderton's Hotel, Fleet-street, E.C.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

March 2 1892.

4,157. H. W. TAYLOR. London. Improvements in shades for electric glow lamps.

4,158. H. EDMUNDS. London. Improvements connected with electric circuits for varying, regulating, or controlling the pressure of electric currents therein.

4,161. F. J. TAYLOR. London. Improvements in regulating the feed of arc lamps.

March 3, 1892.

4 185. P. STIENS. Manchester. A new or improved automatic portable galvanic battery.

4 186. S. J. ROLLASON. London. An improved slow-speed dynamo.

4,190. F. M. A. LAURENT-CELY and E. FINOT. London. Improvements in electrical batteries.

4,192. F. H. NALDER, H. NALDER, C. W. S. CRAWLEY, and A. SOAMES. Clerkenwell. Improvements in and relating to electric meters.

4,244. H. ENDALL. London Improvements in ship's telegraphs.

4,247. H. S. KEATING. London. An electrical cut-out.

4,248. J. BROCKIE. London. Improvements in arc electric lamps.

March 4, 1892.

4,258. W. L. SPENCE. Manchester. Improvements in the wearing parts of dynamo-electric machinery.

4,276. R. W. PAUL and F. KNOWL. London. Improvements in electrical testing instruments.

4,277. A. E. PATTERSON. Rotherhithe. An electric motor.

4,294. W. CROSS. London. Cross's electrical illuminations for clocks, &c.

4,311. W. S. SMITH and H. J. GARNETT. London. Improvements in dynamos.

4,316. E. G. HOFFMANN. London. Improvements in electric welding and in apparatus therefor.

4,320. A. W. MONEY and H. NASH. London. Improvements in apparatus for regulating the arc in electric arc lamps.

March 5, 1892.

4,341. W. L. SPENCE. Manchester. Improvements in the methods of driving electric railway trains.

4,356. W. T. GOOLDEN and S. EVERSHED. London. Improvements in electric measuring instruments.

4,403. W. K. PARTINGTON. London. An electric switch.

4,414. C. COERPER. London. Improvements in and relating to dynamo-electric machines.

4,416. W. H. WESTON and G. W. WESTON. London. Improvements in electric switches.

4,427. J. E. KINGSBURY. London. Improvements in switchboard systems for telephone exchanges. (The Western Electric Company, United States).

4,428. J. E. KINGSBURY. London. Improvements in switchboard systems for telephone exchanges. (The Western Electric Company, United States).

4,429. J E. KINGSBURY. London. Improvements in switchboard systems for telephone exchanges. (The Western Electric Company, United States).

March 7, 1892.

4,456. R. W. JAMES, London. A process for electro-plating. (G. E Gale, United States.)

4,457. R. W. JAMES, London. An apparatus for cleaning the hulls of vessels and other objects for electro-plating. (G. E. Gale, United States.)

4,458. R. W. JAMES, London. An electrode for electro-plating. (G. E. Gale, United States.)

4,464. H. B. LEE and J. C. COOK. London. An automatic electric loom and card-cutting machine.

4,494. F. V. ANDERSEN. London. Improvements in electro-magnetic solenoid apparatus.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1891.

1,050. DE FERRANTI. Distributing electrical energy.

3,127. CRUYT. Electric circuits.

6,213. MARCUS AND OTHERS. Galvanic batteries.

6,247. JOHNSON. (Gendron.) Galvanic batteries.

21,541. PYKE AND HARRIS. Dynamo-electric machine in luctors.

1892.

406. AMERICAN ELEVATOR COMPANY. (Otis Bros. and Co.) Electric motors, &c.

1,147. NEWTON. (Rabbidge.) Telephones.

COMPANIES' MEETINGS & REPORTS.

Direct Spanish Telegraph Company (Limited).

The thirty-seventh ordinary general meeting of this Company was held at Winchester House, Old Broad-street, on Tuesday, March 22, 1892, under the presidency of Sir James Anderson.

The MANAGER (Mr. Charles Gerhardi) read the notice convening the meeting and the minutes of the last meeting, which were confirmed by the present meeting, and signed as correct by the Chairman.

The CHAIRMAN: Gentlemen, I presume you will take the report as read, as it has been in your hands for some time; and I will therefore make a few supplementary remarks on each of the paragraphs in the order in which they occur in the report. The first paragraph is a matter of formal announcement. The second paragraph refers to a decrease in the receipts of £2,214. At previous half-yearly meetings I have foreshadowed that some such result was inevitable if the tariff was further diminished. I do not know of any authentic instance of a reduction of tariff leading to an increase of revenue until several years of commercial growth had elapsed. I have heard some vague statements to the contrary in regard to internal traffic, but I confess myself sceptical on the subject and for external or extra-European traffic it is not possible. There is no instance of such an occurrence; it is, in fact, an axiom in telegraphy that all reductions of tariff must result in a loss at the beginning. I have many times in writing and speaking reminded the public that it took 14 years for our Post Office to get back to the same gross revenue which they enjoyed prior to the introduction of penny postage, and more than 20 years before they got the same net revenue. The result of the penny postage is a favourite argument with advocates for reduced tariffs. We are all familiar with the results of great reductions upon our extended submarine cables both to the East and West. Such reductions have been bold and startling, and such as would, if anything could, have given an impulse to telegraphic traffic; and one would, therefore, have thought that the sacrifice would have been recouped with phenomenal rapidity; but such has never been the case. It has generally been a good deal disappointing, rising quickly at the beginning when the reduction is made, then languishing over a prolonged period until it reaches about the same amount originally expended with the higher tariff. You will find when you examine the different reports of the Companies that this statement is very near the mark. There is a certain amount spent on international telegraphy, and it takes a long time to get anything more out of the public, the process of recouping has been tedious as a rule. Naturally, however, if you reduce the tariff you broaden the basis from which telegraphy may grow, and you may in most cases gradually recoup your losses in a few years, always provided that the reduction has been such as to give a substantial impulse. But what can be said for our poor reduction of a halfpenny per word taken from this Company's proportion of 2½d. per word upon Spanish traffic? We only get 2½d. per word out of the 4d., or rather we used to, but now we only get 2d. per word upon our Spanish traffic, and the halfpenny per word which has been taken off has simply resulted in a loss to us of £1,760. A halfpenny per word can have no effect in retarding or increasing external telegraphic traffic. I do not know whether the tariffs will yet be further reduced, but we need not anticipate, and it is no use crying about it. We did all we could at the Telegraph Conference, and both our Post Office and the Spanish officials did what they could for us. Let us hope, now that the result is again shown, that they will not continue to reduce tariffs, and so make it impossible to maintain submarine cables by private

Digitized by Google

enterprise. Paragraph 3 states that the working expenses are £17 in excess of those of the corresponding period of last year; but, as we have carried 7,800 more telegrams, containing 43,000 more words in that time, I need not detail the items. Salaries and stationery alone show an increase, every other item exhibiting decreases. I now come to paragraph 4, the cost of repairs. You will remember how fondly we cherished the idea of amassing a contingency fund when we talked about the matter a year and a-half ago. I then held out a rose-coloured hope that this might grow with our reserve, and help us to renew our debentures, as well as to reduce their amount in 1894. Well, gentlemen, all this contingency fund is gone, and £2,376 of our reserve in addition, for the purpose of repairing our cables. I may say that I have seldom known of a more fortunate repair than the one in question. Our Bilbao cable developed a bad fault at the end of last October, and in the month of November—one of our worst winter months—it was repaired in 1,900 fathoms near the Bay of Biscay. It was totally interrupted for only three days; but fortunately the Eastern Company had a ship at Lisbon, and did not lose an hour. I have known such repairs to require several months at that season. The problem for your Directors, however, is how to get back that £2,376 of our reserve. We say in the report that we hope to replace it out of future profits—a spendthrift way of looking at such expenditure, you may say, and so it would be but for the fact that the traffic is growing, and your Directors will not bind themselves to pay any given dividend if the traffic shall not warrant it; but we shall watch hopefully, and act as it shall seem to be warranted by the revenue. There seems to us to be an elasticity in Spanish traffic which encourages us to hope for good times, so far as telegraphy goes. Personally, I am trying to believe that the public find they cannot do without the telegraph; and at 4d. per word, with a three minutes' transmission to Bilbao nd 20 minutes to Madrid, if anything will stimulate enterprise such facilities ought to do so. With regard to paragraph 5, there has been some exceptional expenditure amounting to £626. The French Government decided to shift their telegraph office at Marseilles, and we, as well as the Eastern Company, had to follow. The expense of new underground wires will, of course, be heavy, and we had to do a good deal of similar work at Falmouth and Bilbao. I sincerely hope I may have something more encouraging to say at our next meeting. We have a growing traffic, and can only work and watch. If we can be free from repairs, and the Telegraph Conferences will let our poor halfpennies alone, I see no reason for anxiety. I hope before the next Conference comes nearer hand that we shall be able to influence our Government and the different administrations of the European States not to touch these low tariffs. It does not do any good at all. Fourpence per word is nothing in an international telegram, and the worst of it is that we only get twopence out of this fourpence, and the wretched halfpenny off the 2½d. which we used to receive has lost us all this money. I do not know how these cables are to be kept up unless there is a suspension of further decreases of the tariff. If a State chooses to subsidise lines, and make losses, they can, by taxing the community, make up any loss they like. We, however, cannot tax anyone, and we only look forward to being able to do the best we can by appeal, agitation, and entreaty, but we can do no more. I now beg to move:—

"*That the reports and accounts now presented be and are hereby received and adopted.*"

Mr. EDMUND ETLINGER seconded the motion.

The CHAIRMAN: Before I put the resolution I shall be very happy to answer any questions if any shareholder is desirous of asking any. No shareholder rising to address the meeting, he put the motion in the usual way, and having declared it carried unanimously, said: The next resolution is—

"*That the dividend at the rate of 10 per cent. per annum (less income tax) on the preference shares, and a dividend at the rate of 4 per cent. per annum (free of income tax) on the ordinary shares, both for the half-year ended December 31, 1891, be and are hereby declared.*"

Mr. ETLINGER seconded the motion.

The CHAIRMAN put the resolution in the usual way, and it was carried unanimously.

Mr. ETLINGER: The two Directors who retire by rotation are Sir James Anderson and Mr. Denison Pender; and I beg to propose the following resolution:—

"*Resolved, that Sir James Anderson and Mr. J. Denison Pender be and are hereby re-elected Directors of the Company.*"

Mr. DAVID LOWE seconded the motion, which was carried unanimously.

The CHAIRMAN: For myself and my colleague, Mr. John Denison Pender, I beg to thank you; and I think I ought at this point just to say how much I appreciated the kind resolution of sympathy with me which you passed at the last meeting.

Mr. DAVID LOWE proposed:—

"*That Mr. Herbert R. Duke be and is hereby re-elected auditor for the present year, with a remuneration of 20 guineas.*"

Mr. KENNETH ANDERSON seconded the motion, which was unanimously carried.

The CHAIRMAN having intimated that that was the whole of the business,

Mr. COCHRANE said he thought that, although the report was rather discouraging, they ought not to separate before thanking the Directors for the way in which they looked after the interests of the shareholders. He therefore proposed a cordial vote of thanks to the Chairman and Directors.

Mr. CREASEY briefly expressed his pleasure at seconding the motion.

The resolution was carried unanimously.

The CHAIRMAN: We are all much obliged to you. We cannot make things better than they are, unfortunately, and 2d. is a dreadful little tariff to get for this work. It is not a very encouraging result that we present, and yet, after all, it is not disheartening, because I hope that we have got to the ground-floor of the tariff. If so, I do not fear the result. If, however, the tariff goes lower, we shall have to tell you about it. I am extremely obliged to you for your confidence.

The proceedings then terminated.

The Electric Construction Corporation (Limited).

An extraordinary general meeting of this Company was held at Worcester House, Walbrook, E.C., on Tuesday, March 22nd, for the purpose of considering, and, if thought fit, confirming as a special resolution, the resolution which was duly passed at the general meeting held at the same place on March 3rd for increasing the capital of the Company. Also for the purpose of considering, and, if thought fit, passing further resolutions having reference to the mode of issue of such capital. Mr. J. S. Balfour, M.P., presided.

The SECRETARY (Mr. W. Samson) read the notice convening the meeting.

The CHAIRMAN: Well, gentlemen, my first duty is to move a resolution confirming the resolution of the 3rd day of March, 1892, viz.:—

"'*That the capital of the Company be increased to £750,000 by the creation of 25,000 new shares of £10 each, numbered 50,001 to 75,000 inclusive,' be, and the same is hereby confirmed.*"

I presume that most of the gentlemen who are present to-day were present also at the general meeting which was held on the 3rd March, and I need not therefore trouble you with any statement at any length as to the reasons which have induced the Board to advise that this increase of capital should be made. You are aware that the business of the Corporation has increased in the most satisfactory manner, and that we are informed by our Works Director that the works are quite full, and there is every reason to anticipate, if we increase the capital, that we shall be able to take some very large and very lucrative contracts. All this was stated at the previous meeting, and the resolution for increasing the capital was unanimously approved at that meeting. I now move that the resolution be confirmed. Mr. Courtenay will second it.

Mr. COURTENAY: I beg to second the resolution.

The resolution was unanimously carried.

The CHAIRMAN: We now come, gentlemen, to the mode of issuing this capital, and the resolution which I have now to read is one which has been drawn up by our solicitors, and it is as follows:—

"*That one-half of the said new shares, being those numbered 62,501 to 75,000, inclusive, be allotted and issued by the Directors to such persons and at such times as the Directors shall think proper, and that the said shares shall be preference shares, and shall entitle the holders thereof to a cumulative dividend at the rate of 7 per cent. per annum on the amount credited as paid up thereon, in priority to any dividend on the ordinary and founders' shares of the Company.*"

This proposal has met with the approval of the founders; and that, I think, is probably the best evidence that it is to the advantage of the Company. I may state what is present to the mind of the Board is that at the present moment we probably shall be able to raise, in fact we have at the present moment offers to subscribe for, a considerable portion of this preference capital; we believe we could raise something of this amount, not probably so much as the whole £125,000 (we do not want to raise so much as that at present), but £50,000, £60,000, or perhaps £75,000 of preference capital, we could raise that, and use it to very great advantage indeed. We believe that the probable claims upon capital, so far as we can foresee, will be met by £125,000 of additional capital. We think when that is raised that by that time the ordinary shares will be at a premium, and we have every reason to believe that we ought to be able, certainly with the business which we have in view, to put a premium, if we want to, upon any additional capital we may be able to raise by means of ordinary shares, and that premium will go to the reserve fund. You will observe in the resolution that it is stated that these shares shall be issued and allotted by the Directors to such persons as the Directors may think fit. Of course, the Directors consider themselves bound by the terms of the prospectus, and by all the assurances they have ever given to the ordinary shareholders, to offer these shares in the first instance to the ordinary shareholders, so that every ordinary shareholder shall have an opportunity of acquiring some of these preference shares if he so thinks fit. Having carefully considered the matter, the Directors believe that this is the most likely mode in which the capital, which is so urgently required, can be raised, and which does not exceed £75,000, but which I think will not probably exceed £60,000. We think this the best mode of doing so, and we have taken the best advice we could get from brokers and others in the City of London; and everybody seems to think—and we have evidence that it will be so—that these shares will be taken up, by the fact that several of the Directors and the shareholders have expressed their willingness to subscribe for much more than their proportion. We shall offer the shares we issue to the ordinary shareholders in proportion to their holdings, and if they take them up I think they will secure a very good investment indeed. I move this resolution, which will also be seconded by Mr. Courtenay.

Mr. COURTENAY seconded the resolution, which was unanimously carried.

Digitized by Google

Mr. ROWE: I should like to ask, Sir, whether you propose—supposing you issue a part of these shares—whether you propose to call them entirely up or to issue the remaining portions? Now I think it much better to call up each portion as it is issued.

The CHAIRMAN: Hear, hear.

Mr. ROWE: Because the shares will get more valuable if they are called up. There is always great anxiety about shares if a large call can be made upon them; and therefore I should urge—suppose half of them are allotted now—that these should be called up before the whole are issued. As to another matter you have touched upon, I agree that the shareholders should have a chance of taking up this capital.

The CHAIRMAN: Hear, hear.

Dr. DRYSDALE: I suppose we have to vote upon this question upon the supposition, which is perfectly clear from what you have stated, that we may expect greater dividends in the future—I do not say you commit yourselves to that—but I presume you mean that the dividends are likely to be more than they have been, because otherwise it would be a pity to borrow money at 7 per cent. and to give only 6 per cent. That is the only point upon which I desire information.

The CHAIRMAN: Yes, of course; we are large shareholders ourselves, very large holders of ordinary shares. I myself am a very large holder of ordinary shares, and I should not like to see capital put before mine if I did not think that it would be to the benefit of the ordinary shareholders. I cannot conceive with these contracts we have in view and those immediately in hand—if we obtain these orders—I cannot conceive but that there will be a considerable ultimate increase in the dividend to the ordinary shareholders. With regard to the question asked by Mr. Rowe, of course our intention is to call up the shares in full which are issued at present; to make the calls fairly easy, of course, but to call the shares up in full. I agree with Mr. Rowe that it would not be desirable to have preference shares issued with a considerable liability upon them; and, looking at the present day and at the present condition of the Money Market, it is really better to have as little liability on shares as possible. I think prudent investors prefer to make their payments at once, and get rid of the liability. If there are no other questions to be asked I will put the resolution. Those in favour of the resolution please signify in the usual way. On the contrary. It is carried unanimously. Then the next resolution is:—

"*That the said preference shares shall also entitle the holders thereof, upon a return of capital of the Company, to be repaid the amounts credited as paid thereon, before any payment in respect of capital is made on the ordinary and founders' shares of the Company.*"

Mr. Courtenay will second that.

Mr. COURTENAY seconded the resolution, which was unanimously carried.

The CHAIRMAN: That, gentlemen, concludes the business of the meeting, and I thank you very much for your attendance. There will be a confirmatory meeting held on Thursday, April 7th, but it is only *pro formâ*, and notice of it will be duly sent out to you.

A vote of thanks to the Chairman for presiding closed the proceedings.

The Gülcher (New) Electric Light and Power Company (Limited).

The fourth ordinary general meeting of this Company was held at Winchester House, Old Broad-street, London, on Monday last; Mr. D. De Castro, Chairman of the Company, in the chair.

The SECRETARY (Mr. T. C. Morgan) having read the notice convening the meeting, and the minutes of the previous meeting having been confirmed,

The CHAIRMAN said: Gentlemen, I dare say you have all read the report and balance-sheet, and I wish to say that, if any shareholder would like a copy of the manufacturing and profit and loss accounts, it lies on the table, and the perusal of these accounts will enable any shareholder, if he so choose, to criticise them when the proper time arrives. In adopting this course, we are following the precedent of last year, and we are following the statutes enacted for the purpose of regulating joint-stock companies. The reason for postponing the meeting so long was that it took some time after my return to England to interpolate the New Zealand accounts into the general accounts of the Company, and it took some further time to make myself master of the general position of the business. Hence the delay. As you are aware, I went to New Zealand in December, 1890, in order to get some private Bills through the Colonial Parliament; and I am happy to say that we have obtained one Bill for Wellington, one for Christchurch and one for Auckland. I believe the first two are of very great value. As to the Auckland one, I think it too will become valuable in time, but in Auckland the gas interest was rather too strong for me, and I was obliged to make a compromise. I felt that, rather than risk the loss of two valuable Bills already obtained for the sake of getting a third, I would consent to the third being reduced in value. You know, gentlemen, the difficulty that we were plunged into some four years ago, on entering into a contract for the lighting of the City of Wellington. Our late Manager, rightly or wrongly, made a tender to light, as he thought, three miles of streets. As a matter of fact, we have lighted the streets of a city three miles long. Mr. Mountain estimated that the contract would cost us £2,500; but it gradually grew, as you recollect, to £3,500, to £4,500, and finally it reached £14,500. We managed to find the £14,500, and although, as stated in the report, the income from public lighting was only £1,750 per annum, reduceable in three years to £1,600 per annum, while it cost the Company nearly £1,300 per annum to maintain; yet the contract was, on account of the private lighting clauses contained in it, of considerable value, provided Parliamentary powers could be obtained to authorise private supply. It was resolved, therefore, that I should go out to obtain such Parliamentary powers if possible. Another reason for sending me to New Zealand was that serious litigation with the Corporation of Wellington was threatened, which it was most desirable to avoid. At the end of the first year's working the Corporation thought that they had a claim to be paid a sum (amounting to about £530 per annum) on account of water which they alleged that the Company used in excess of what the Corporation had contracted to supply, and they deducted this sum from the £1,750 which they ought to have paid us. This was a very serious matter, as it made the public lighting contract an absolute loss. Lastly, the working of the contract was necessarily extravagant from the fact that the current was supplied from two central stations nearly a mile apart, involving the maintenance of two sets of drivers, stokers, and attendants. Well, gentlemen, to cut a long story short, I have managed to concentrate the two stations into one, and to reduce the working expenses by more than one half. I have arranged the dispute with the Corporation, and made an entirely new contract with them; and whereas the public lighting contract was producing, at best, £300 per annum, it is now producing upwards of £1,200 per annum net.

Major COTTON: Net? And since when?

The CHAIRMAN: Since October 1, 1891. It will come into next year's accounts. Having got my three Acts of Parliament as above stated, and made the arrangements and contracts I have just sketched out, I cannot help feeling that my journey has been a very great success, and I trust that from the New Zealand Electrical Syndicate, in which we are very largely interested, we shall derive a very great benefit. With regard to the loss during the past year shown in the balance-sheet, this is distinctly traceable to the depression which fell upon business in England after the failure of Messrs. Baring's house. For the first time during the last nine years our year's receipts from sales in England have decreased; and, during our financial year 1890-1891 they decreased by £2,500, while the business in New Zealand was temporarily at an enforced standstill. You will see, gentlemen, if you refer to the accounts before you, that on the credit side of the profit and loss account, we take credit, not only for the sales and hire of dynamos and lamps in England, but also in New Zealand. The sales in England are rather less than they were during the preceding 12 months. I can find no reason for it except that orders generally fell off during the last three months of 1890 and the first six months of 1891. They began to increase again during the last six months of 1891; and I attribute this falling off during the first nine months partly to the blight which fell upon business generally all through England last year, and partly to the enforced stoppage of our business in New Zealand under the circumstances mentioned to you. We could not do anything over there, when the funds which belonged to us were kept in the hands of the Corporation. Taking into consideration these two facts, I think it is not to be wondered at that the Company did not do quite so much business as in the preceding year. Since June, 1891, the sales in England have again improved. An agency has been opened in Italy, and a new field has been opened in the colony of New Zealand which promises to be a large and permanent customer of the Company. This is, perhaps, a convenient point at which to tell you more in detail what has been done in New Zealand. (Here the Chairman went at length into the details of various businesses done and contracted for in New Zealand and other Australasian Colonies by him during his absence.) Subsequently, referring to the accounts, he said the balance sheet is very much in the same form as it was the last time I had the pleasure of meeting you. There is a total preference share capital paid up of £36,497. 11s. 4d., with £178. 8s. 8d. unpaid calls. The first debentures remain at £8,000, bearing interest at £6 per cent., while the whole of the £10,000 £10 per cent. debentures have been paid off except £500, which will be discharged in February, 1894. After discussing various items in the accounts and answering various questions by shareholders the Chairman moved the adoption of the Report and the passing of the accounts placed before the meeting.

Mr. HENRY GRÈWING seconded the motion.

Mr. STUDD thought that every shareholder in the room would desire to convey his congratulations to Mr. De Castro upon his being with them again, after his journey to the antipodes, of which he had given so interesting an account. He trusted that all Mr. De Castro's hopes might be realised. After discussing the accounts he asked whether the Directors had considered the propriety of following the example of the Brush and other electrical companies who had amalgamated with engineering firms, and had increased their business in that direction.

The CHAIRMAN said Mr. Studd had suggested an amalgamation. That had been his own desire for several years, and if the Directors could see their way to such an amalgamation they would be very glad to consider it. He had already tried it once, but without success. After further discussion, in which Major Cotton, a large shareholder, took part, the report and accounts were agreed to.

On the motion of Mr. STUDD, seconded by Major COTTON, the retiring Directors, Mr. Grèwing and Captain Levett, were re-elected; and, on the motion of Mr. LAMONT, seconded by Mr. BINSWANGER, Mr. Russell Day was re-elected auditor.

The CHAIRMAN then having intimated that the business of the meeting was at an end, Mr. STUDD moved, and Major COTTON seconded, a vote of thanks to him; and the meeting terminated.

The London Electric Supply Corporation (Limited).

The following annual Report of the Directors of this Corporation has just been issued. The meeting of shareholders will be held at Cannon-street Hotel, E.C., to-day (Friday), at 12 o'clock.

The Engineer's Report appended hereto describes in detail the general position of the works.

The result of the year's working was adversely affected by the fire which took place at the Grosvenor distributing station on November 15, 1890, which caused an entire cessation of the lighting for a space of three months. After supply was resumed on February 16, 1891, it was found that many of the Corporation's old customers had resorted to other companies. Although a considerable amount of new business has been gradually acquired, it was only towards the end of the year that the number of lights installed equalled those connected at the time of the fire. Advantage was taken of this interruption to business to reorganise the system of distribution. The whole of the overhead cables were removed and concentric underground cables substituted; at the same time the distributing mains were extended to many districts in the authorised area of supply which had not previously been touched, and where there is good prospect of remunerative business being obtained.

The extension of electric lighting generally has been less rapid than was anticipated, but the light is undoubtedly growing in public favour. The greatly improved supply now given by the Corporation gives reason for anticipating a material increase of business during the current year.

As referred to in the Engineer's Report, measures are being taken by which the cost of producing the current will be very materially diminished, and the efficiency of the generating plant increased.

During the year the engagement of Mr. de Ferranti has ceased by effluxion of time. Mr. P. W. D'Alton, the chief assistant to Mr. de Ferranti during the construction of the generating station, has been appointed chief engineer. The Directors retiring, as provided by the Articles of Association, are Mr. James Staats Forbes and the Hon. Reginald Brougham, both of whom are eligible for re-election. The auditors, Messrs. Kemp, Ford & Co., who retire in accordance with the Articles of Association, offer themselves for re-election.

The following is the Engineer's Report above referred to:—

"At the commencement of the year 1891, owing to the fire at the Grosvenor Station in November, 1890, when much of your transformer plant and other apparatus was destroyed or seriously damaged, your Central Station at Deptford was supplying no current. When supply was resumed on the 16th February, 1891, only 9,000 lights were at once installed, and the number gradually increased to 36,000 by the end of the year.

"In the interval the two dynamos, each of 625 H.P., were removed from the Grosvenor Station and erected at Deptford, with two new tandem compound horizontal engines. Until August last these dynamos furnished the supply unassisted; the current, generated at 2,400 volts, being transformed up to 10.000 volts, and at that pressure transmitted to the distributing stations in London.

"The two dynamos, each of 1,250 H.P., which, prior to November, 1890, had supplied current direct to the mains at a pressure of 5,000 volts, were, during the latter end of 1890 and the early part of last year, altered to generate current at 10,000 volts. An unsuccessful attempt to run one of them was made towards the end of July, but they were not ready for work until August 10th, about which time I took over the duties of engineer-in-chief. Since then all these machines have been in work, the larger ones generating current at 10,000 volts.

"During the past autumn considerable difficulties were experienced in working the 10,000 volts system, and there were occasional failures of the dynamos, high-tension transformers, and trunk mains, many of which were due to the present arrangements for working the machines in parallel. Unfortunately, these failures have caused interruption of supply on several occasions; but measures have been, or are now being taken, by which it is believed these difficulties will be overcome. For the last four months there has been great improvement, and breakdowns have been of very rare occurrence.

A number of faults occurred in the trunk mains during the year, but they are now causing us less trouble and anxiety. I am of opinion that such faults are more or less inseparable from any new system, and that they will eventually be eliminated. During the first four months after the resumption of supply the failures were numerous; during a second similar period they diminished to less than half, and latterly they have been gradually ceasing.

"Similar troubles were experienced with the high-tension transformers, but as the year advanced the failures became less frequent, owing to careful repairs, and during the last four months we have had but one failure.

"A few months since we established at Deptford a new department, where we repair transformers and make various parts of machines for maintenance and renewals. The work already turned out by the department is equal to anything we have had done by outside contractors, and superior to most of the work supplied to us; at the same time a considerable saving in money is effected, and work is more promptly done.

"The work on the 10,000 H.P. dynamos was suspended in May last by your order, but the parts of the machines have been properly protected and are in good condition.

"The distributing mains have been greatly extended during the past year, and, as there are now upwards of 27 miles laid, a large increase in the volume of business may reasonably be anticipated. They are in a thorough state of efficiency, and have caused but little expense for maintenance or repair.

"The permanent switching gear is now being erected at the distributing stations, and will shortly be completed. At two of the stations it is already in use and is working satisfactorily.

"The engines and boilers have been kept in good working order. The two sets of generating plant of 625 H.P. cannot be worked to their full capacity owing to faulty design, in consequence of which it is impossible to produce a larger output than 8,500 to 9,000 lights from each. This defect is about to be remedied to a considerable extent at a moderate outlay.

"A scheme for condensing the exhaust steam has been approved by you, and I am getting forward with the preparations for the work. When completed, which I hope it will be by July next, it will greatly improve the running of the engines, and will have the effect of saving at least 25 per cent. of the consumption of coal.

"P. Walter D'Alton, Engineer-in-Chief.

"Stowage Wharf, Deptford, March 10, 1892."

The Engineer's Report is followed by a note from Dr. Fleming:—

"I have read the Report of your Chief Engineer, and, having been associated with him as your scientific adviser in the working of the system during the past year, I generally concur in that Report.—J. A. Fleming, M.A., D.Sc., University College, London, March 11, 1892."

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "The Electrician" Electrical Trades Directory and Handbook, 1892, pages 308-322, *&c., &c.*]

ASSAM-BENGAL RAILWAY COMPANY (LIMITED).—This Company was registered on March 18, 1892, with a capital of £1,500,000, in £10 shares, by Freshfield and Williams, 5, Bank-buildings, E.C. Among the objects is included that of purchasing, taking on lease or otherwise acquiring, working, and turning to account telegraph and telephones, and "to carry on in all their respective branches all or any of the businesses of manufacturers of engines and all kinds of rolling stock, mechanical engineers, electrical engineers, electricians, manufacturers and purveyors of electricity for the purposes of light and power," &c.

CHANNEL TUBULAR RAILWAY PRELIMINARY COMPANY (LIMITED).—This Company was registered on the 17th inst. with a capital of £40,000, in £4 shares, by W. Wills, Broadway Chambers, Westminster, S.W. The objects are to acquire the patents or rights to use and exercise the patents, concessions, rights and business of the submerged tube system of railway between England and France (Sir E. J. Reed's patent), and to take all necessary preliminary steps required for the construction of a tubular railway through the Straits of Dover as a means of communication by steam or electric locomotion.

ELECTRIC LIGHTING AND GENERAL DEVELOPMENT SYNDICATE (LIMITED).—This Company was registered on March 21, 1892, with a capital of £700, in £10 shares, by C. W. and H. B. Taylor, 31, Crutched-friars, London, E.C. The objects are to acquire, by grant, purchase, transfer, lease, hire, or otherwise, from any sovereign government, corporation, municipality, authority, or otherwise, concessions, licences, grants, decrees, rights or privileges, public and private, and to exercise, manage, carry on, promote or form in any part of the world, any business, undertaking, company, or trade, in pursuance of any such concessions, licences, &c. The number of Directors will be as far as possible kept to not less than three, the first being William Warriner, E. J. Rhodes, and George Morison. Remuneration, £2 per cent. upon whatever net profits are divided by the Directors among the shareholders. Registered office: 31, Crutched-friars, London, E.C.

MERRYWEATHER AND SONS (LIMITED).—This Company was registered on March 22, 1892, with a capital of £110,200, divided into 6,000 £6 per cent. preference or "A" shares of £10 each; 200 management or "B" shares of £1 each; and 5,000 ordinary, or "C" shares of £10 each, by Peake, Bird, Collins, and Peake, 6, Bedford-row, W.C. The objects are to enter into and carry into effect an agreement between James C. Merryweather of the one part, and the Company of the other part, and to carry on in the United Kingdom or elsewhere, the manufactures, trades and businesses acquired under the said agreement, including that of fire engine manufacturers, fire escape manufacturers, hydraulic engineers, electrical engineers, general engineers, pump-makers, hose-makers, coppersmiths, boiler-makers, makers of all classes of fire-extinguishing appliances, and other allied businesses carried on by the said J. C. Merryweather at London, Greenwich, and elsewhere, under the style of "Merryweather and Sons." The number of Directors is not to be less than three nor more than seven, the first being J. C. Merryweather (the "governor"), A. Essex, E. P. Williams, C. J. W. Jakeman, and L. Miller.

NEWPORT METAL STAMPING COMPANY (LIMITED).—This Company was registered on the 21st inst., with a capital of £3,000, in £50 shares, to carry on the business of mechanical and electrical engineers, iron workers, brass founders, tin stampers, lamp manufacturers, &c.

EASTBOURNE ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of the above-named Company, made up to November 8, 1891, was filed on February 25, 1892. The Company was registered on February 15, 1882, with a capital of £50,000, in £10 shares. At the time of making up, 1,017 ordinary and 40 preference shares had been taken up, the full amount called, and all calls (£10,570) paid.

Digitized by Google

ELECTRO-CHEMICAL SYNDICATE (LIMITED).—The following letter has been received by the Registrar of Joint-Stock Companies:—"The Electro-Chemical Syndicate (Limited) *did not go to allotment*, and has never transacted any business." The Company was registered on October 16, 1890, with a capital of £5,000, in £1 shares, and has never filed any returns.

ELIESON ELECTRIC COMPANY (LIMITED).—A letter has been received from the late secretary (T. P. Gower) of the above-named Company, stating that the Company "has ceased to carry on business for two years past."

INTERNATIONAL ELECTRIC SUBWAY COMPANY (LIMITED).—The registered office of the International Electric Subway Company (Limited), formerly at 43, Threadneedle-street, London E.C., is now situated at Albany Buildings, 39, Victoria-street, Westminster, S.W.

LAURENCE, SCOTT AND COMPANY (LIMITED)—The annual return of the above-named Company, made up to January 6, 1892, was filed on March 7. The Company was registered on August 10, 1868, with a capital of £30,000, in £10 shares, under the title of "Laurence, Paris and Scott (Limited)." At the time of making up, 1,205 shares had been taken up, of which 300 had been issued as fully-paid as part of the purchase consideration. Upon the remaining 905, the full amount has been called and all calls have been paid.

MEXICAN GAS AND ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of the above-named Company, made up to December 23, 1891, was filed on March 9. The Company was registered on April 24, 1883, with a capital of £100,000 in £20 shares, to acquire the exclusive privilege of lighting the capital of Mexico, and the cities of Puebla, Orizaba, Cordova, and Jalapa, in the Republic of Mexico. At the time of making up, all the shares had been taken up, and all were issued as fully paid, in full satisfaction of the purchase price. Of the 5,000 shares, A. O. H. Gibbs, of 15, Bishopsgate-street Within, London, E.C., holds 4,994. Registered office: 15, Bishopsgate-street Within, London, E.C.

NEW TELEPHONE COMPANY (LIMITED).—The following notice was filed on February 22, 1892:—"At an extraordinary general meeting of the New Telephone Company (Limited), duly convened and held at 147, New Bond-street, London, on January 26, 1892, the subjoined special resolution was duly passed, and at a subsequent extraordinary general meeting, also duly convened and held at 3, Carlton House-terrace, London, on February 16, 1892, the subjoined special resolution was duly confirmed:—'That the Bill submitted to the meeting, entitled "A Bill to provide for dissolving the New Telephone Company, and for re-incorporating the Company, and defining its capital, objects, and powers," be, and the same is hereby approved, subject to such additions, alterations, or variations, as Parliament may think fit to make therein, and the Directors shall sanction.' Signed Marlborough, Chairman."

NORTHERN ELECTRIC WIRE AND CABLE MANUFACTURING COMPANY (LIMITED).—The annual return of the above-named Company, made up to February 24, 1892, was filed on March 8, 1892. The Company was registered on June 25, 1889, with a capital of £20,000, divided into 660 vendors' and 3,340 ordinary shares of £5 each. At the time of making up, all the vendors' and 1,512 of the ordinary shares had been taken up, of which the vendors' shares had been issued as fully paid. Upon the remaining 1,512 ordinary shares £2. 10s. per share had been called, resulting in the payment of £3,777. 10s., and leaving £2. 10s. per share unpaid.

ORIENT ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of the above-named Company, made up to December 31, 1891, was filed on March 16, 1892. The Company was registered on November 29, 1887, with a capital of £5,000, divided into 20 shares of £250 each, to engage in preliminary investigations and negotiations in India, Burmah, and elsewhere, with a view of initiating a business on a large scale for the application of electricity for lighting and other purposes, and to carry on in the United Kingdom, India, Burmah, Ceylon, and elsewhere, the business of electricians, mechanical engineers, suppliers of electricity and manufacturers of and dealers in electrical apparatus. Thirteen of the 20 shares have been taken up, £100 called on each share, and all calls paid. Registered office: 2, East India-avenue, Leadenhall-street, London, E.C.

PLANET ELECTRICAL ENGINEERING COMPANY (LIMITED).—The annual return of the above-named Company, made up to December 31, 1891, was filed on January 12, 1892. The Company was registered on March 26, 1889, with a capital of £20,000 in £5 shares. At the time of making up (December 31, 1891), 2,757 shares had been taken up, of which 800 had been issued as fully paid. Upon the remaining 1,957 shares the full amount had been called, resulting in the payment of £9,535 and leaving £250 in arrears.

PORTLAND ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of the above-named Company, made up to January 14, 1892, was filed on January 21st following. The Company was registered on November 30, 1887, with a capital of £45,000, in £5 shares, to enter into contracts for electric lighting and for the supply of electrical energy. At the time of making up, seven shares had been taken up, the full amount called, and all calls (£35) paid. No agreements for the acquisition of any contracts, business, plant, &c., have been filed.

CITY NOTES, &c.

ANGLO-CANADIAN ASBESTOS.—A dividend of 20 per cen for the year 1891, free of income-tax, has been declared by the Directors of this Company, being the same as for 1890.

A. AND J. STEWART AND CLYDESDALE.—At the annual meeting of the shareholders of this Company on Monday a dividend of 10 per cent. for the half-year, equal to 9 per cent. on the whole year, was declared, against 12½ per cent. last year. The difference was said to be due to the higher rate of labour, and to the fall in prices obtained for their production. The net profits for 1890 were £97,210, whereas last year they were £85,460, being a difference of £11,750. Depreciation now stands at £65,567. £4,000 was voted as Directors' fees for this and last year.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED). (Four and a-Half per Cent. Perpetual Debentures).—Letters of allotment and regret have been posted.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended March 20th were £897, as against £767 in the corresponding period of last year, showing an increase of £130. The total receipts to date, from January 1, 1892, are £9,727, against £8,481 for the corresponding period of 1891, an increase of £1,246.

COMMERCIAL CABLE COMPANY.—The following synopsis of the Directors' report, which was submitted and adopted at the annual meeting in New York on the 21st inst., has been published:—The year's earnings amounted to $1,904,717; the working and other expenses for the year amounted to $819,392, leaving a balance of $1,085,325. Dividends of 1¾ per cent. each were paid for the quarters ended March, June, September, and December, being a total of 7 per cent. on the capital stock of $7,716,000, and absorbing $540,120. The balance of the year's profits, amounting to $545,204, together with $29,796 from the profit and loss account of 1890, aggregating $575,000, was transferred to the reserve fund. On January 15, 1891, debenture bonds were redeemed to the amount of $600,000, and provision was made for the redemption of $600,000 of bonds on January 15, 1892.

PACIFIC TELEGRAPH COMPANY (LIMITED).—The subject of the laying of a Pacific cable has from time to time been mooted, and it may be interesting at this juncture to set out particulars relating to the Pacific Telegraph Company (Limited), which was registered in November, 1886, with a capital of £2,000,000 in £10 shares, to establish, make, maintain, work, and use telegraphs, telegraphic, telephonic, or other communication, submarine and overland, in and between Australia, New Zealand, and other islands and places in Australasia or the Pacific Ocean, Africa, America, Europe, or any of them; to enter into, make and fulfil any contracts or arrangements with the Imperial Government of the United Kingdom, or any Foreign or Colonial Legislature or Government, or other public authority, relative to the construction, acquisition, letting, hiring, use or working, of any telegraphs, or other communication used, or intended to be used, in connection with the objects or purposes of the Company. The subscribers to the Memorandum and Articles of Association were the Earl of Miltown, Sir James Corry, Bart, M.P.; Sir Daniel Cooper, Bart.; Viscount Folkestone, M.P.; Hugh G. Reid, J.P.; Sir Alfred Slade, Bart.; J. Henniker Heaton, M.P.; C. M. Young (banker), Captain E. Palliser, Randolph C. Want, W. J. Clarke, P. Perkins of Brisbane, S. Wilson, Murray G. G. Finch Hatton, and George Coote, F.S.I., and each of the above took one share in the Company. The number of the Directors was not to be less than three nor more than nine, the first to be appointed by the subscribers, and until such appointment the subscribers themselves were to act. The first registered office was situate at 34, Clement's-lane, Lombard-street, E.C. The last return made up to April 23, 1891 (filed on May 20, 1891), shows that out of a capital of £2,000,000 18 £10 shares had been taken up, and the full amount called, resulting in the payment of £130, and leaving £50 in arrears. The following are the only shareholders, each holding one share:—

Countess of Miltown, 2, Buckingham Gate.
Sir J. P. Corry, Bart., Dunraven, Belfast.
Sir D. Cooper, Bart., 6, De Vere-gardens, London.
The Earl of Radnor, 8, Ennismore-gardens, London, S.W.
H. G. Reid, J.P., Warley Hall, near Birmingham.
J. Henniker Heaton, M.P., 36, Eaton-square, S.W.
E. M. Young, 21, Palace-gate, Westminster, banker.
Major Edward Palliser, 91, Earl's Court-road, S.W.
R. C. Want, 32, Victoria-street, S.W., solicitor.
Sir W. J. Clarke, Bart., 27, Queen's-street, Melbourne.
The Hon. J. Perkins, Brisbane, Queensland.
Sir S. Wilson, M.P., Grosvenor-square, W.
The Earl of Winchilsea, Haverholme, Sleaford.
G. Coote, Smeetham Hall, Sudbury.
Sir Donald Smith, K.C.M.G., 88, Cannon-street, E.C.
Sir Sandford Fleming, C.M.G., Ottawa, Canada.
Owen Jones, Esq., Thatched House Club, St. James's-street.
Arthur Blackwood, Melbourne Club, Melbourne, merchant.

No agreements of any kind have been entered into. Present registered office unknown.

ROCKHAMPTON (QUEENSLAND) GAS AND COKE COMPANY (LIMITED).—In the report of this Company for the seven months ended December 31st last the Directors state that "Since the last general meeting a definite step has been taken in the matter of the electric light. After careful consideration it was decided to instruct the Company's London agents to invite applications for the position of electrical engineer to the Company; and out of a large number of applicants, Mr. A. E. Neal, of Birmingham, was selected. He has reported on the systems of electric lighting most suitable for Rockhampton. As the early introduction of the electric light will be advantageous to the Company in a variety of ways, the Directors have decided to proceed with it without delay, and have accordingly purchased a quarter of an acre of land in Alma-street,

Digitized by Google

between William and Denham streets, for the erection of the works. Upon the frontage of this site, general offices and show-rooms will be erected for the convenience of the numerous customers in both sections of the Company's business, and the Directors are strongly of opinion that the removal of the offices to a more central position than the present one will be conducive to an increase of business. The Directors have undertaken to supervise, through the electrical engineer, the electric light operations at the Mount Morgan Gold Mining Company's works." The Company pays a dividend of 10 per cent., free of income tax, and carries forward £16. 16s. 9d.

STOCK EXCHANGE.—The following have been placed by the Committee of the Stock Exchange for quotation in the Official List:—Elmore's French Patent Copper Depositing Company's vendors' shares, Nos. 66,751 to 100,000; and General Hydraulic Power Company's additional shares, Nos. 60,001 to 70,000.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the fortnight ending March 15, 1892, amounted to £2,908, as compared with £2,986 in the corresponding period of last year, a decrease of £78.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ending March 18, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,181.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 724.—Vol. XXVIII. FRIDAY, APRIL 1, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The candour and frankness of Mr. Graff Baker's remarks at the discussion on Mr. Reckenzaun's Paper were thoroughly appreciated, and we hope that his statements will appear in full in the *Journal* of the Institution of Electrical Engineers. He had declined to give the figures of the Leeds line to the author of the Paper, since they needed certain preface and qualifications, and some men having given these explanations would have withheld the statistics. It is easy to understand that a 200 H.P. engine running at 75 H.P., cannot be expected to work economically. It is clear that American wheels may not be suitable for English rails. It is less easy to understand the difficulty of getting men to look after motors; and we cannot understand why so many details, which have been worked out with so much care by the Thomson-Houston Company, are found to give very inferior results when put to work in this country. We say that we cannot understand it, but we are not surprised at it. Three weeks ago we drew attention to the wide and still increasing divergence between American and English engineering.

There can be little doubt that accumulator traction must cost more than the overhead system in actual running expenses, exclusive of cost of plant. The North Metropolitan Tramway Company offered 4½d. per car mile for the electrical working of their line; and the contracting company, while realising that the number of cars was too small to make this pay, accepted the figure as a reasonable one, and attained a very fair degree of success. But Mr. Graff Baker, with the very latest equipment fresh from the land of electric railways, spends 6·63d. per car mile. This result is very interesting. We have been taunted by our American friends for our backwardness in electric traction, and it was supposed that the Leeds line was going to show us how to do it. We shall wait with interest the developments and improvements which are sure to be made, and the success which will in every probability attend Mr. Graff Baker's efforts. But if it is a matter of starting at 6½d. per car mile, and then developing and improving, why, we could do that without American assistance!

It is unmistakable that the Thomson-Houston system is all cut and dried so far as its use in America is concerned, and it is equally clear that the conditions of traction in England have been completely misunderstood by the engineers of that company. No sooner was the City and South London Railway open than the New York papers were full of schemes for a similar and practically identical line for that city. The case of the Leeds tramway may, perhaps, be a proof of the contention which we have so often put forward, that little or no useful comparisons can be made between English and American electrical engineering practice. We must gang our ain gait.

The debate in the House of Commons on Tuesday evening, which resulted in the rejection of Dr. Cameron's motion for the purchase of the telephones by the Government by 58 votes, was maintained at a high level of accuracy and interest by no means usual when a question involving technical knowledge is discussed by the Legislature. Dr. Cameron stated his views in a few well-considered words, and Mr. Quilter did not fail to make the utmost of the case for the National Telephone Company. Sir James Fergusson, while unable to accede to the motion, had a friendly word to say for everyone concerned, and especially for the telephone companies themselves.

The Chancellor of the Exchequer was of opinion that the Civil Service might well be congratulated on the fact that the House was so very ready to trust a vast and novel business to the management of the best abused of all public departments, and one which already employed 100,000 men, an army which the Government hesitated to increase. In the result, the country was committed to the Government half-way house scheme, from which sanguine Post Office officials appear to anticipate a sort of telephonic millennium, notwithstanding that almost every speaker was in favour of State control, and prophesied that in the end the Government would have to take another and a bolder step.

"A good deal of my life," said Mr. Forbes at the meeting of the shareholders of the London Electric Supply Corporation on Friday last, "has been passed in trying to make the best of a bad business, and it seems to me that that is what I have got to do to-day;" and without doubt the present situation of the Deptford scheme was bravely faced, and all the consolation that was possible was extracted from the succession of misfortunes that has beset it. Even after having to announce that a £50,000 five per cent. loan was to be raised

Digitized by Google

by mortgaging the entire property of the Company, the chairman's armoury of philosophic dicta was not exhausted. A despairing shareholder was told that misfortunes were only to be redeemed by knowledge, and by courage; the Company could only be redeemed by people with sound information, not by mere talk; the Directors believed "in sticking to the thing;" some said he (the Chairman) was too sanguine, but the world was not carried on by "wet blankets," and his sanguineness was founded on his knowledge of difficulties overcome in other things. It is evident that the round peg is in the round hole this time.

It has been suggested by one of the learned counsel in the Lane Fox case that after the admirably clear and complete judgment which has been delivered, we ought to withdraw our remarks about Mr. Justice A. L. Smith's knowledge of electrical science. But does not the perfect lucidity and accuracy of this judgment redound greatly to the credit of the members of the Bar (to say nothing of the witnesses) who have succeeded in fifteen days in imparting a sound and sufficient knowledge of electricity, a clear notion of the charging and discharging, the practical use of secondary batteries, and a very clear grasp of the working of a supply system? What professor could do as much for a class? What crammer has done so much for a student? Those who are paid by results may well long for such a receptive and patient pupil.

When a committee of experts was nominated in connection with the Crystal Palace Exhibition, we remarked that there was a splendid opportunity for doing something, but we could not say what. A good suggestion or two appeared to be urgently wanted. Four months have passed, and not only have no tests been made, but no suggestions even have been heard of. All the meters in the Exhibition might have been coupled up in series on a bank of lamps, or a resistance, or a suite of furnished rooms. Even if the committee of experts did not decide as to which of the records was the most accurate, the readings might have been published, and the makers left to fight it out amongst themselves. The plebiscite system might be introduced, and a gold medal awarded for the meter which came nearest to the average of the whole. The voltmeters, ammeters, and other instruments might be judged in the same way. The jury would be saved a great deal of trouble, and the farce would not be much greater than it promises to be at present.

Kilkenny.—The Town Council have decided to borrow £12,000 for the purpose of establishing electric lighting works.

Gearless Motors.—The Short Electric Railway Company, of Cleveland, has secured from the Minneapolis Street Railway Company an order for 120 of their gearless motors.

The Government and the Telephones in Holland.—The Haarlem Chamber of Commerce has petitioned the Dutch Government to purchase the telephones, on the ground that the present service is both inefficient and expensive.

Physical Society.—Owing to the pressure on our space this week we have been compelled to hold over the discussion on Mr. R. W. Paul's Physical Society Paper on "Some Electrical Instruments," which will be found in the present issue.

Electric Traction in the Malay Peninsula.—It is proposed to build a light passenger electric railway from Singapore to Kranjie, connecting therewith a steam launch running to Johore. A concession has been granted, and the line commenced.

The General Electric Power and Traction Company.—We regret to learn that the works of this Company have been closed by order of the Board. We understand that the business of the Company will be carried on by the Electric Construction Corporation.

Gutta-Percha Cultivation.—M. Serullas, who received a subsidy from the Société d'Encouragement to assist him in his researches on the cultivation of gutta-percha in the Malay Peninsula, has written to the president of that society announcing successful results.

Sir John Pender, K.C.M.G.—During Sir John Pender's recent visit to Constantinople the Sultan conferred upon him the gold and silver medals of the Order of Imtiaz. This distinction is usually reserved for such of his Ministers as His Majesty honours with his personal friendship.

Nottingham.—Owing to the fact that many manufacturers and merchants have either provided themselves with installations or have intimated their intention of doing so, the Electric Lighting Committee of the Town Council have decided to take active measures for supplying the town.

Lightning.—Captain Calvert, of the Allan Line steamer "Prussian," on arriving at Greenock from Boston, reported that on the evening of March 6th a flash of lightning struck the mizenmast, stripping away about 12 feet of the timber, and setting fire to some hay which was below.

Taunton.—At a special meeting of the Town Council last week it was decided to employ an expert to prepare a report upon the suitability of the present buildings and plant for the lighting of the town by electricity, and that another special meeting of the Council should be held on Thursday, April 21st.

Electrical Bills in Parliament.—At a meeting of the Committee of Selection the following members were appointed to serve upon the Joint Committee of the Lords and Commons upon Electric and Cable Railway Bills:—Messrs. Stansfeld, Whitmore, J. S. Gathorne-Hardy, T. H. Bolton, and Story-Maskelyne.

University College, Liverpool.—Prof. Lodge has, with the approval of the Senate, appointed to the Demonstratorship in Electrotechnics Mr. Francis Gibson Baily, B.A., Assoc.I.E.E., late scholar of St. John's College, Cambridge. Mr. Baily took first-class honours in the Natural Science Tripos, and is now in the employ of Messrs. Siemens Bros. and Co.

Electrical Standardizing, Testing, and Training Institution.—The annual dinner of the students of this Institution was held on Wednesday evening at St. James's Hall. Lord Castletown of Upper Ossory took the chair, and among those present were Lord Russell, Prof. Robinson, Major Waller, Mr. Robert Hammond, Mr. Harrison, and Dr. Fleming.

Royal Society.—The following Papers were down for reading yesterday before the Royal Society:—"An Improved Apparatus for ascertaining the Sensitiveness of Safety Lamps when used for Gas-Testing" (and two other Papers), by Prof. F. Clowes; "Aberration Problems," a Discussion concerning the Motion of the Ether near the Earth, by Prof. Lodge, F.R.S.

Asbestos Porcelain.—On page 189 of our issue of December 25, 1891, we gave some particulars of a kind of porcelain made from pure powdered asbestos by a M. Garros. The conductivity of this material, when employed as the porous pot of a primary battery, has been tested at the Laboratoire Centrale d'Electricité, and found to be 2·75 greater than that of the porous pots usually employed.

Report on the Thunderstorms of 1888 and 1889.—A report, by Mr. William Marriott, on the systematic investigation of thunderstorms, has been issued in the Journal of the Royal Meteorological Society. No very definite conclusions have been arrived at; but attempts have been made to ascertain the paths and rate of travel of thunderstorms, and their relation to the distribution of atmospheric pressure.

Digitized by Google

Liverpool.—It will be remembered that a short time since fires occurred in some of the junction boxes in Liverpool. Major Cardew was recently sent down by the Board of Trade to make an examination, and a copy of his report has been submitted to the Watch Committee of the Corporation, and the city engineer has been instructed to make an inspection of the street boxes, and present a further report to the Committee.

O.S.A. Smoking Concert.—One of the best concerts ever given by this society took place on Friday last at Masons' Hall Tavern. Messrs. Adams, Deane, Dundas, Fitzgerald, and Russell were the vocalists. Mr. Melrose was excellent in the humorous sorgs, Mr. Crawley gave some very original recitations, and Mr. Slocombe was the violinist. Messrs. Lamb and Norman acted as accompanists. The next smoking concert will be the last this season.

Erding.—The town of Erding in Upper Bavaria has decided to adopt electricity for both public and private lighting. Power will be derived from a waterfall, a little over two miles distant. Messrs. Siemens and Halske, of Berlin, will carry out the work on the "drehstrom" system. The primary current will be conveyed at 1,000 volts, being transformed down to 115 volts. Applications have been received for connecting a large number of motors. The firm has undertaken to complete the work within six months.

Electricity in Ceylon.—Progress is being made with the work of utilising water-power to supply electrical power to Mariawattee factory, says the *Indian Engineer*. A water-course is now being constructed, and buildings are being erected for the turbines and dynamos. It is proposed to obtain 200 H.P., 50 H.P. for each of the two factories belonging to the Company, and 100 H.P. available for others in the neighbourhood who may wish to hire power from them. It is estimated that the cost of the installation will be £4,000.

Gas and Electricity in Paris.—In a recent report to the Conseil Municipal of Paris M. Paul Brosse gives some statistics with regard to the relative positions of gas and electricity in that city. The consumption of gas continues to grow, although the rate of increase is somewhat less than it was. The Paris central stations have at the present moment plant capable of developing 17,500 H.P.; when complete this figure will become 32,000. During 1891 the gas consumed in Paris amounted to 10⅗ million thousand cubic feet. Out of 85,000 houses only 20,000 are fitted with gas.

The Benevolent Fund of the Institution of Civil Engineers.—This fund has entered upon its twenty-eighth year. The invested capital is £[illegible]8,137. 0s. 2d., and the dividends realised on this account in 1891 amounted to £1,359. 18s. 11d. The annual subscriptions, derived from 768 subscribers, yielded £1,548. 18s. 6d., or not quite one moiety of the income. The actual receipts during the year were £3,413. 9s. 11d. The payments included grants aggregating £3,245. 5s., in 55 cases. The auditors call attention to the small cost of administration, which is only 3 per cent. of the receipts.

Telephone and Electric Light Wires in Germany.—The induction between electric light and telephone circuits has been the subject of considerable investigation and discussion in Germany, due to the intention of the German Postal Telegraph authorities to push a Bill through the Reichstag, giving them the power to do pretty well what they like with overhead or underground conductors carrying "energetic currents." There is great opposition to the Bill, its opponents alleging that the telephone wires can be properly protected against induction without the exercise of any such powers as are asked for.

Coast Communication.—On Tuesday last Sir E. Birkbeck asked the First Lord of the Treasury whether, in view of the great importance of rendering every facility for the better preservation of life and property round the coast of the United Kingdom, he would be good enough to grant an early opportunity for a debate on the question of coast communication. Mr. Balfour said it was impossible for the Government to make an exception in favour of a particular resolution, although they were in hearty sympathy with the objects in view, and he hoped that something material would be done towards carrying them out.

The London and Paris Telephone Line.—Experiments have been recently made by the technical staff of the Post Office on various forms of transmitters in connection with long-distance telephony. The two circuits were coupled together at Paris, and speech was transmitted over about 620 miles of line, from one room in the General Post Office to another. Conversation has been carried on with complete success between London and Marseilles on several occasions; but it is not intended to open this route to the public at present. The Post Office pattern of Gower Bell, and a modification of the Hunnings transmitter are found to be as good as any other on this line.

Cable Interruptions and Repairs:

* Not yet re-established.

The School of Electrical Engineering and Submarine Telegraphy.—We are informed by Mr. L. Drugman, Manager of the above school, that, as the result of the recent examinations held by Mr. Gisbert Kapp, the following gentlemen have obtained the certificate:—Messrs. P. W. Burman, W. J. Davy, W. Dickinson, L. Goichot, C. H. Gray, L. Leskovic, S. E. Linsell, and R. A. Smith. The examination consisted of a Paper in mechanical engineering, a Paper in electrical engineering, a *viva voce* and practical examination; also engineering design done during the term and average of two test examinations; 66 per cent. of the marks were necessary for the obtaining of the certificate.

Underground Mains in Paris.—According to *l'Industrie Electrique*, the Compagnie Continentale Edison has had difficulties with its underground mains. The type of conduit originally adopted (see *The Electrician*, Vol. XXIII., p. 250) was very similar to that known to us as the Crompton system. But in Paris, as in London, want of space precluded its universal use. The Company, therefore, looked out for a system which, while occupying less space, should still allow of bare copper conductors being run everywhere. At this juncture Jacob Frères, of Pouilly-sur-Saône, suggested rectangular earthenware troughs. These were used in places, and at first gave good results. After a time, however, the insulation fell, owing to infiltration and chemical action, and the Edison Company has now reverted to its first plan.

The Thomson-Houston Company at Work in Germany.—At Berlin, says our correspondent, the "Elektricitäts-Gesellschaft Union," that is the Thomson-Houston Company, is busy preparing for an important move. There is a rumour to the effect that this Company will swallow up several of the smaller fry, who are at present doing a good business, though without the necessary capital behind them. The German capitalist "sits upon his money," and the civic authorities also sit upon their's, and both of them are waiting for the production of electricity to become cheaper and for the experts to agree upon one system as being the best. At present if three of these learned gentlemen are consulted they give three different answers, and as each of these answers takes a whole year to be fully digested the whole matter is relegated into the distant future.

The London County Council Subways Bill.—The Select Committee of the House of Commons, presided over by Mr. H. Gladstone, resumed their consideration of this Bill during the week. Sir Frederick Bramwell, who was the first witness, said there was an essential difference between a gas or water pipe and an electric main. He pointed out that an electric main was a comparatively small object, and that the capacity of a system of electric mains could be added to without breaking up the streets, which was not the case with gas or water

Digitized by Google

pipes. If it were rendered obligatory to remove the mains into the subways the public would be exposed to a great deal of annoyance, and the companies would be put to a large expense. Dr. Hopkinson, Prof. Kennedy, Major-General Webber, Mr. R. E. Crompton, and Mr. F. Bailey also gave evidence against the Bill.—On Wednesday the Committee decided not to exempt the electric lighting companies from the operation of the Bill, but decided that any cost which they might be put to in complying with the provisions of the Bill was to be borne by the County Council.

The Chicago Exhibition.—The Electrical Committee appointed by the Royal Commission for the Chicago Exhibition met on Monday, the 28th ult. The Chairman (Mr. W. H. Preece) reported that he had received information from Chicago that one of the engineers of the electrical staff of the Exhibition was about to be sent over to this country to confer with the Committee on the question of arranging for some portion of the Exhibition to be lighted by European firms. It was agreed to postpone the consideration of this question pending the arrival of the gentleman in question. The Chairman also informed the Committee that there was every prospect of the electrical industries of this country being adequately represented. Several of the newest forms of engines and dynamos for electrical installations would be shown; and it was probable also that arrangements would be made for showing a series of rooms, furnished in the English style, and fitted with the most recent applications of the electric light. The Attorney-General stated in the House of Commons a few days ago that the Royal Commission had asked for a substantial increase of the Government grant.

Relation of Voltaic E.M.F. to Molecular Velocity.—In a recent research published in Vol. VIII., p. 63, of the *Proc.* Birm. Phil. Soc., 1892, Dr. Gore shows by means of an extensive series of 64 tables of measurements of mean volta E.M.F., that the dilution of the liquid of a voltaic cell by means of water or alcohol, the liquefaction of either the positive or negative metal of the cell by means of mercury, the dilution of either of these amalgams by means of mercury, the dilution of one solid metal by means of another in an alloy, is universally attended by an increase of mean E.M.F. of the diluted and diluting substances, and consequently also of the actual E.M.F. of the diluted one, provided that in all cases no chemical union or other chemical change occurs in the mixture. The manifest explanation of this extensive general result is, that by the act of solution or dilution, the molecules of the active substance are separated farther apart, and consequently acquire increased velocity of motion. In proportion, however, as chemical union occurs, the gain of E.M.F. diminishes, and is converted into a loss, and the loss is larger in proportion as the chemical union is stronger. The method enables chemical compounds in alloys, amalgams, and electrolytes to be distinguished from mere mechanical mixtures.

Engines for the Electric Light.—A correspondence has been recently running in the columns of the *Engineer* on the subject of engines for electric lighting purposes. The following is an extract from "A Volt's" latest contribution to the controversy:—

"I am quite content to concede that the Willans engine will run for 10 years, or even 20 years, if that will satisfy 'I. I. I.;' but even he will admit, I suppose, that the Willans engine is not immortal; and as he evidently knows all about it, is it too much to ask him to tell your readers in what way it generally fails when it does fail? If it does not go to pieces all at once, then it fails by degrees—a bit at a time. I want to know which bit, in his experience, fails first, and has to be replaced. The simplest plan would be to say what is the maximum sum he has known to be paid for repairs of a Willans engine of fair size, say indicating 50 H.P. in any one year. This is information that will go home to the hearts of steam users. I know of an instance in which a slow-speed horizontal mill engine by a Belgian firm ran for 10 years without the outlay of one sixpence in repairs. The letting of the brasses together was done on Sundays by the engineer in charge. The piston was not drawn for ten years, and it was in fair condition and steam-tight at the end of that time. I myself indicated and reported some years ago on a Watt engine, made in 1819, which had worked twelve hours a day for 44 years, and had the original brasses in. This engine had cost next to nothing for repairs. I do not suppose that any high-speed engine will give such results as this. But I gather from 'I. I. I.'s' letter that something like it may be expected. But I do not want to know what may be expected. I want to know what has actually taken place. Surely your correspondent, or someone else who has used the Willans engine, can give some information. I am told many things good and bad of it. Let us have the facts. One thing, for example, that I have heard is, that dirty steam will ruin the piston valves, even going so far as to set them fast and lead to a breakdown. Has this ever happened? Would I be quite safe in putting a Willans engine to work with a water-tube boiler, which primes furiously if it is not cleaned out once a fortnight?"

The Influence of Polyphase Currents on Telegraphic and Telephonic Circuits.—During the working of the Lauffen-Frankfort transmission plant the German postal telegraph authorities carried out a series of experiments with a view of testing the effect upon their lines of circuits carrying polyphase currents. On the first four single-wire telephone circuits selected, which varied in length from 1 mile to 3½ miles, and which were at an average distance of 10 metres from the disturbing circuit, a constant humming was heard, which in wet weather rendered all conversation impossible. Tests were next carried out on two private telephone lines. One of these started at a great distance from the polyphase current wires, and crossed them at a given spot. The other line ran alongside the Lauffen-Frankfort circuit at a distance of from 5 to 15 metres for a little over half a mile. Both lines were rendered useless. On the Heilbronn-Mosbach circuit, 18 miles long, telegraphic communication was exceedingly difficult. On several other telegraph circuits whenever 25,000 volts were applied to the Lauffen-Frankfort line, the armatures of the electro-magnets kept up a continual vibration. Experiments were also carried out on the Stuttgart-Heilbronn double-wire telephone circuits (7½ miles). With 10,000 to 15,000 volts on the Lauffen line a noise was heard which increased with the voltage applied until with 25,000 volts on all conversation was rendered inaudible. The general conclusions to be drawn from these experiments are as follows:—(i.) The influence of polyphase currents (increasing with the voltage) was felt on lines traversed by telegraphic and telephonic currents and placed at an average distance of 10 metres from the disturbing circuit, for stretches ranging from ½ to 18 miles. (ii.) Lines merely crossing the Lauffen-Frankfort wires were disturbed, as well as complete metallic circuits.

The National Telephone Company.—The London general staff of the National Telephone Company held their annual dinner in the Chapter-room of Anderton's Hotel, Fleet-street, E.C., on Friday last; the chair being occupied by Mr. Dane Sinclair, and the vice-chair by Mr. Thomas Fletcher. Amongst about 70 members of the staff present were Mr. Calder, Mr. Turner, Mr. Phillips, and other heads of departments. An excellent dinner was provided, after which the evening was devoted to music and speech-making. The latter function is usually somewhat depressing; but on this occasion the chief members of the Telephone Company's staff gave expression, in tones of unmistakable sincerity, and in forcible language, to their views upon the rights and wrongs of the "Telephone Question." After the usual loyal toasts, Mr. Fletcher proposed, in a brief speech, "The National Telephone Company, its President, Vice-President, and Directors;" and in replying to this toast the Chairman went sympathetically into the burning question of the opposition to the National Company—more especially the opposition of the Post Office. It was claimed by Mr. Sinclair that the difficulties which have been overcome, and which have to be overcome before the telephone can attain its perfect success, are known only to the men whose every day duty it is to face these difficulties. He then dwelt upon the personal popularity of the President and Vice-President of the Company, and upon their willingness to meet in every possible way the wishes of subscribers to the telephone, if only Parliament would aid them in so doing. Without such aid complete success was impossible. If the Post-Office decided to take over the telephones, this aid from Parliament would be not a whit less essential to that Department. The speaker also feelingly referred to the assistance rendered to the chief officials of the Company by the "most capable and complete telephone staff in the world," and concluded by inviting those present—and especially the young men—to stand by the Company and manfully support them in their efforts to secure a perfect telephone service, in spite of the opposition of those who, now that success was within sight, wished to snatch the credit of this success from them. Mr. Sinclair was warmly applauded, a proof that he correctly gauged the feelings of his audience.

NOTES ON SUBMARINE CABLE WORK.

BY H. D. WILKINSON.

(*Continued from page 517.*)

6. Buoying the Cable.—Some reference to the preparations made on board for buoying cable may be of interest. The buoy is first got ready, the flagstaff and flag put on, and the buoy slung on to a block and tackle secured to a convenient place in the rigging. In this position the buoy is outside the shrouds and resting on two wooden skids ready for lowering, the fall on the block being of sufficient length to lower the buoy into water. Fifteen fathoms of mooring chain are reeved through the eye at the bottom of the buoy and fastened at the top in one of the slip links, while a short length of bridle chain is attached to the other slip link on the buoy and shackled below to the mooring chain as shown in Fig. 22. The bridle-chain and slip links do not come into use till the ship is about to heave up the cable-end again, after having completed the repair on the other end; but their use may be briefly explained. When the ship is up to the buoy on the return journey, a boat is put off with hands to attach a line from the ship to the bridle chain. The line is connected to the drum of the picking-up gear on board, and after heaving up a little, the bridle chain is freed from the buoy. The strain of the cable is then taken by heaving up a little more, and the mooring-chain can then be disengaged from the buoy.

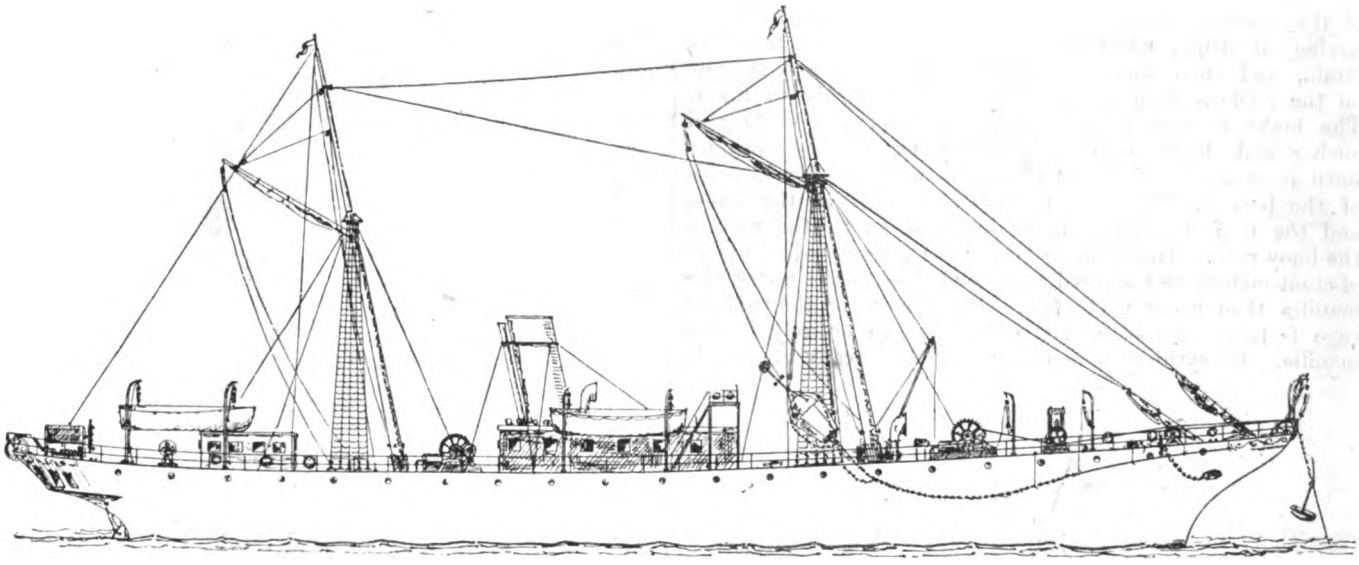

FIG. 21.—Cable Ship preparing to Buoy Cable.

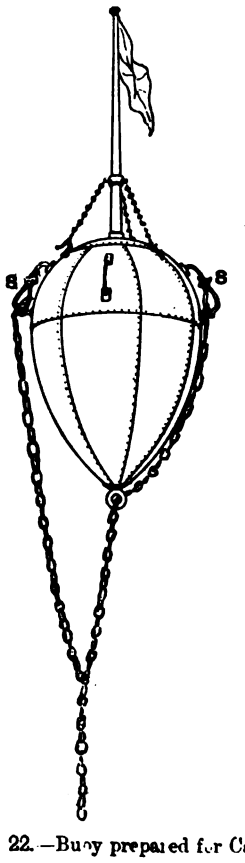

FIG. 22.—Buoy prepared for Cable.

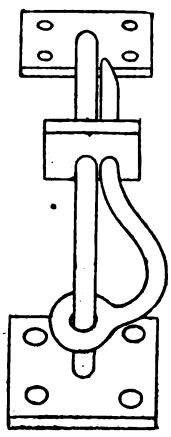

FIG. 23.—Snatch Link on Buoy.

The slip links (S S, Fig. 22) are for disengaging these chains easily, when freeing the buoy. One of these links is shown in detail in Fig. 23. The link is in two parts, one of which is a loop of iron rod fixed permanently on plates rivetted to the buoy, and the other a piece of bent rod tapered at one end and working on the lower part of the fixed loop. The diagram shows the link as fixed, and held together by a square washer holding the tapered end of the moveable loop against the fixed one. To open the link this washer is given a smart blow upwards, when the moveable part falls and disengages the chain.

Another way of attaching the bridle chain to the buoy without the use of a slip link is practised with buoys having rigid iron stays, supporting the flagstaff ring, instead of chains, as shown in the engraving. Such buoys are only provided with one slip-link, which is used for the mooring chain, but have in addition a chain permanently fastened round the body of the buoy, to which the bridle chain is attached a few feet from its end by a seizing of spun yarn. The few feet of slack on the bridle chain are then made fast to one of the rigid flagstaff stays by taking two round turns on the stay and then two seizings of spun yarn. When the ship is up to the buoy on the return journey a boat with hands is put off to the buoy, one of whom cuts adrift the seizings to the stay, and unwinds the round turns. He then has the few feet of slack chain over the bow of his boat, and shackles the end of the same on to the drum line of wire rope thrown from the ship. While he is doing this there is no downward pull on the chain, as it is still held by the seizing on the buoy chain. As soon as shackled the ship heaves in a little on the drum line to take up the slack, and on the word of command from the ship the man in the boat cuts the last seizing adrift. The ship now has a clear way to take the strain of the cable, and after heaving up a little more to take the strain off the mooring chain on the buoy, the man rows round to the slip link on the other side of the buoy, and on the word of command from the ship to "knock up," gives the washer on the slip link a blow upwards, opening the link, and allowing the mooring chain to slip off, leaving the buoy quite free.

But to return now to our preparations for buoying. On the end of the mooring chain about 20 fathoms of rope are attached, and the chain and rope so attached to the buoy are

Digitized by Google

led along outside the ship to the bows and held a few feet above the water by pieces of small line tied to the gunwale, a few feet apart. The appearance of this is sketched in Fig. 21, which represents a cable ship preparing to buoy cable. Meanwhile the end of the cable at the bows is prepared for mooring. The mushroom anchor is attached directly to a length of mooring chain, while a few fathoms away from the mushroom another chain is attached to the mooring chain, the other end of which is made fast to the cable. The chain is put on the cable with back hitches and stoppered on with spun yarn. The free end of the mooring chain is shackled to a rope wound over the paying-out drum, which is heaved in a little to take the strain, and then heavily braked. The stopper first put on the cable is then cut adrift, and all is ready to lower. The brake is now released gradually, and the cable and anchor sink below water, while the paying-out continues until it is known that the anchor is within a few fathoms of the bottom. The rope is then stoppered at the bows, and the nearest thimble in it shackled on to the end of the buoy rope. The bight so formed is then secured to a piece of stout manilla and lowered overboard close to the water, the manilla then being made fast. The stopper on the paid-out rope is then released, and the strain taken entirely by the manilla. Everything is now overboard and ready to launch,

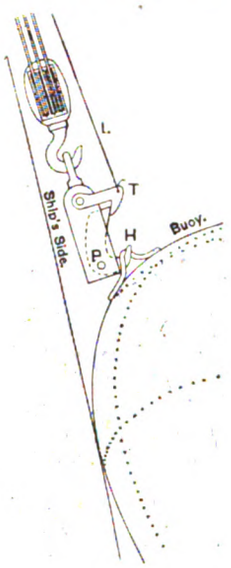

Fig. 24.

and it only remains to lower the buoy into the water by the tackle. The buoy is slung to the tackle by a detaching hook, H (Fig. 24). This is set into a ring on the buoy as shown, and is pivotted at P, and kept in an upright position by the trigger, T. To free the buoy, the line L is pulled on deck, lifting the trigger and freeing the hook, which, pulled down by the weight of the buoy, turns over on the pivot and allows the buoy to fall into the water. This done, the manilla is cut adrift, and immediately the small rope supports holding up chain and rope to ship's side are torn away by the strain, and the buoy, with the cable anchored below, floats free of the ship.

(To be continued.)

SOME ELECTRICAL INSTRUMENTS.*

BY ROBT. W. PAUL.

The increasing number of cases in which accurate electrical measurements have to be made, render it more than ever necessary to devote attention to the design of instruments, with the object of making their use more convenient and expeditious as well as accurate.

Consider, for example, the form in which the standard ohm is usually constructed, the coil having two or more layers of many turns each; in using such a coil for accurate measurements there is considerable delay in waiting for the temperature of the coil and water-bath to become uniform and equal, and even then an uncertainty remains as to whether the turns near the top of the coil are at the same temperature as those at the bottom.

After heating the bath, even with stirring, the water at the top may be at a higher temperature than that at the bottom. The

Fig. 1.

surface from which heat generated in the coil may be got rid of by conduction and convection, is comparatively small.

Prof. Fleming, in a Paper read before this Society in November, 1888, pointed out these disadvantages, and described a coil in the form of a ring of square section, which to a great extent obviates them. But even this coil has some length, and it has seemed possible to go still further in this direction, and at the same time to simplify the construction.

In the ohm coil shown in Fig. 1 the wire is wound in a flat spiral, being first doubled on itself in the usual way to avoid self-induction; the spiral is enclosed between two thin brass plates, forming part of a very thin, flat, water-tight box, and the electrodes pass up the central tube. The wire is thus at one level in the liquid, and has, therefore, a better opportunity of acquiring a uniform temperature, which may be accurately ascertained by a delicate thermometer passing down the centre, with the bulb at the level of the spiral; a second thermometer, in the water, at the same level, serves to check the uniformity of temperature. In order that the width of the coil may not prevent

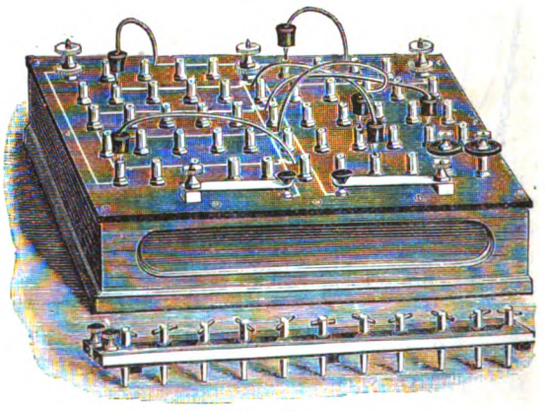

Fig. 2.

any slight convection currents from having free play, the screws which hold the plates together have large holes through them. Following Prof. Fleming's suggestion, the upper ebonite insulator is formed into a cup to contain paraffin oil to prevent surface leakage through deposited moisture.

The resistance box shown in Fig. 2 is the outcome of some attempts to improve the ordinary form. The coils are arranged in sets of ten each, and their ends are connected to sockets

* Paper read before the Physical Society, March 25, 1892.

Digitized by Google

fixed in rows on an ebonite board. Successive coils are put in circuit by placing a plug, attached to a flexible cord, in the required socket. Thus the resistance may be increased from 1 to 11,110 ohms by steps of one ohm if necessary. The advantages which accrue from this arrangement are found to be as follows:—The danger of surface leakage across the ebonite from block to block in the ordinary form, where the narrow gap between them is not easily kept clean, is obviated by the large open space between the sockets. The contact resistance in circuit is constant and easily measured; it is reduced to a minimum by each plug fitting solidly, the contact being over the whole of its circumference instead of on about one-third of it, as in the ordinary form. The hole between the blocks of an ordinary resistance box alters its form with temperature, or any warping of the ebonite board, but the contact resistance at these sockets is not affected thereby. A rise in temperature of 20° C. will make the longer diameter of an ordinary resistance box plug-hole one-half per cent. greater than the shorter, owing to the difference between the coefficients of expansion of ebonite* and of brass. The flexible cords each consist of between two and three hundred strands of fine copper wire, and are not found to be affected by use.

In using the set of coils as a Wheatstone bridge, or as an ordinary resistance box, the rapidity and ease of adjustment of the well-known "dial" form are preserved, while the instrument is more compact and portable; the plugs, being attached to the instrument, are not liable to be mislaid.

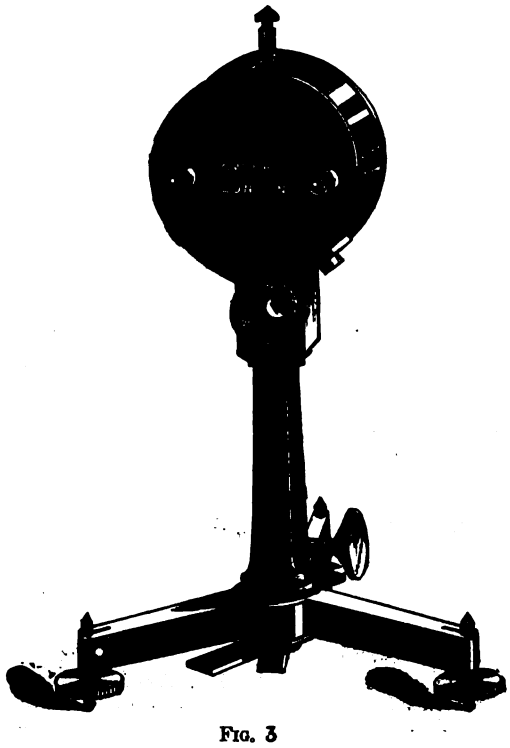

Fig. 3

But the arrangement of the instrument renders it available for several other uses. By means of the special contact bar shown in the illustration, from 2 to 10 coils in each row may be placed in parallel, thus making the instrument available as a conductivity box of large range for measuring low resistances. For the measurement of currents by the voltmeter method, 10 one-ohm, or 10 one-tenth ohm coils may be placed in parallel to give accurate resistances of 0·1 and of 0·01 ohm good carrying capacity. Several derived circuits may be made in the one resistance box.

By means of the contact bar, large ratios between two resistances of great importance in the construction of high resistances may be accurately obtained. To do this the method described by F. Kohlrausch† is employed; for example, one set of ten coils being put in parallel so as to nearly equal the other set of ten coils in series. The small difference (error) between the two is ascertained by Foster's method. Then each of nine of the higher resistances being checked against the first of its series, all the data for finding the exact proportion between the first coil of the one set and the other set of ten in parallel are ascertained.

The set of coils may be used as a potentiometer by connecting the battery to its terminals and using a pair of travelling plugs, between which any resistance from 0 to 10,000 ohms may be included.

The reflecting galvanometer, illustrated in Fig. 3, has coils enclosed in ebonite boxes turned out to fit them. They are wound in accordance to Sir W. Thomson's law for the greatest magnetic effect at the centre, each being provided with terminals, they can be joined up as desired, and a pair of high or of low resistance coils may be used in the same instrument. When used as an astatic galvanometer, one of the needles is placed at the back of the mirror which moves in the thick metal box below the coils, and the plug which carries the window in front may then be pushed in to aid in damping the vibrations of the needle by air-friction. The needle may be easily removed, the suspending fibre passing through a slot in the case. It can be replaced by a ballistic needle, in which case the mirror carries no magnets, and the air-damping can be minimised by sliding out the plug. This part of the instrument is mounted on an ebonite pillar to give good earth-insulation, and the directing magnets are placed at the base, so that they may be adjusted without setting the instrument in vibration.

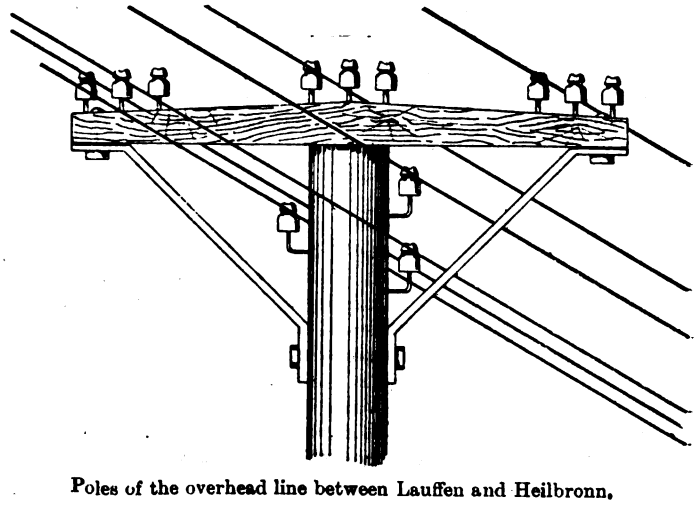
THE LAUFFEN-HEILBRONN TRANSMISSION PLANT.

[Communicated.]

The "drehstrom" installation at Heilbronn is working, though not working equally well in all its parts. The total water-power of the Portland cement works at Lauffen some 6 miles off,



Poles of the overhead line between Lauffen and Heilbronn.

is 1,500 H.P., of which 600 H.P. are used by the works themselves, the rest remaining available for electrical purposes. There are five 300 H.P. turbines, running at 35 revolutions. One of these drives an Oerlikon dynamo, giving 50 volts and 4,000 amperes at 150 revolutions, with a frequency of 40 ∿. The 50 volts are transformed up to 5,000 volts for transmission. It is a remarkable fact that the oil insulation has been taken away from all the high-pressure converters, practical experience having shown several inconveniences, of which, however, Herr O. von Miller does not like to give detailed accounts. At least, Herr Meissner, his engineer, who gave these details at a meeting of the Elektrotechnische Verein at Frankfort, did not answer any of the questions, asking for the causes of the failure of the oil insulation. Oil is, however, still retained within the line insulators. The line (*see* figure) consists of three bare copper wires ¼in. in diameter, which had to be placed 5ft. above the trees, and 12ft. above the houses, which entailed the use of poles 36ft. to 48ft. high. Each of these poles carries

Digitized by Google

mine oil insulators, thus providing for a future increase of the plant. At the lower part of the poles there are small wires for measuring purposes and telephonic communication between the town and the generating station, the former only being able to call the latter by disconnecting the voltmeter leads and thus making the voltmeters at the station swing back to zero. The line terminates before it reaches Heilbronn at a small cottage containing the step-down transformers which convert the 5,000 volts into 1,500. From this cottage triple concentric cables lead to the places where the tertiary transformers are banked, each sub station containing at present only one 40 kilowatt transformer and space for a second one. These tertiary transformers step down from 1,500 volts to 100.

All the house-wiring is done upon the three-wire system, with three-pole fuses. Installations under 10 lamps are wired upon the two-wire system only; but three wires enter the house, and from the main fuse that part is taken which experiment shows to be the best. The incandescent lamps are now burning well, though they are sometimes subjected to fluctuations of pressure of from 3 to 4 volts. Before the equal distribution of the lamps upon the two sides of the three-wire network had been thoroughly carried out these fluctuations amounted to 7 volts. The calculated losses in the leads are 14½ per cent. in all, of which 10 per cent. takes place in the overhead wires, and 3 per cent. in the 1,500 volt cables, leaving 1½ per cent. to be debited to the distributing mains, a loss which, in face of the above-mentioned fluctuations, seems a trifle under-estimated. The line has withstood a heavy snow. Of "drehstrom" motors there are three at work, two of 2 H.P. each, and one of 6 H.P., the former without the latter with sliding rings. The 6 H.P. motor is said to take nearly 50 amperes for running without load, but not much more if running under full load. The meters used are of Dr. Aron's well-known type.

ELECTRIC LIGHTING BY WIND POWER.

The windmill which was erected by Messrs. Carwardine and Co. at their flour mills in the City-road, London, some two years ago, has for the last three weeks been connected to an electric lighting plant, which is now running successfully. The windmill was erected by Messrs. Alfred Williams and Co., of Great Eastern-street, and is of the American wheel or disc type. The lathes are self-adjusting, to suit the varying pressure of the wind, and the mechanical construction is very substantial. A framework of 10in. timber is carried on an upper floor to a considerable height above the roof. The power which has hitherto been used for milling and hoisting is now employed to drive an Elwell-Parker dynamo by means of a countershaft and belt. An automatic switch is connected to the dynamo, and cuts in when about 70 volts is reached, dropping out again at about 50 volts. A battery of 28 E.P.S. cells is used, and the dynamo charges them with a variable current which rises during a fair breeze to 30 amperes. On the overhanging end of the dynamo shaft a centrifugal governor, such as is used for train-lighting, is mounted. When a certain speed is exceeded a switch arm is pushed over and puts resistances into the shunt winding of the field-magnets. Two arc lamps and a number of glow lamps are run off the batteries, and the light is highly appreciated by the proprietors of the mills. The electric plant was put down by Messrs. Wenham and Co., of Upper Ogle-street, W.

A Paper was read by Prof. J. Blyth at the Royal Scottish Society of Arts in January last, on some experiments on the application of wind power to the driving of dynamos, and a very large mill erected by Mr. Brush at Cleveland was described in *The Electrician*, Vol. XXVI., p. 290. Very little practical advance has however been made in this direction. There are several difficulties to be met in making the apparatus perfectly automatic; and it appears that if wind power is to be seriously used for country houses, &c., it would be better to stop charging while the lights are being used. In any case, the first cost must be considerable, and while windmills are being replaced by steam-engines, even in Holland, where the use of wind power is best understood, it does not seem profitable to attempt to do more than 3 or 4 H.P. by this means.

Windmills have shown themselves to be better adapted for pumping than for any other work. A curious example has been described of a Californian windmill. It was desired to store up the power, but as water was very scarce, the wheel was arranged to hoist dry sand into a reservoir, and this was used to drive an overshot wheel when power was wanted. The Genevese system of hydraulic storage might, perhaps be successfully applied to windmills. A three-throw force-pump might be provided with a variable stroke or its equivalent, in connection with a governor. With light winds the back pressure would not pull up the mill, but it would continue to store, though slowly. Every stroke of the force-pump would deliver a definite quantity of water, whether the mill was running fast or slow, and no waste would occur, as when resistances, cut-out switches, and batteries are used. A single pipe only would be needed for both storage and delivery, and the lights could be run from a turbine-driven dynamo whether the windmill were pumping or no. The only drawback, but one which is so fatal in tide-mill schemes, is the first cost.

NORMAL AND HISSING ARCS.*

BY J. R. CRAVATH.

The electric arc has heretofore been investigated more from a purely electrical than from a broad physical standpoint. The relation of voltage, current, resistance, &c., in different arcs has received more attention than the action taking place in the arc itself. In other words, the arc has been dealt with through the agency of the voltmeter and ammeter, rather than "face to face." The electrical part of the work having, therefore, been pretty thoroughly done, this Paper will treat only of the action of the arc itself.

The normal silent carbon arc, Fig. 1, consists of a stream of carbon vapour appearing to arise from the boiling crater on the positive carbon and touching the white hot point on the negative. This cone-shaped stream of vapour burns where it comes in contact with the surrounding air. The whole surface of the crater is in a steady

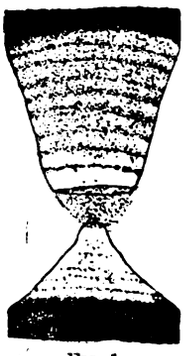


FIG. 1.
The Normal Silent Arc.

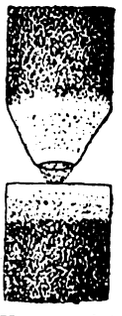

FIG. 2.—Upper pointed carbon positive. No hissing when positive carbon is moved horizontally.

boil and gives off vapour equally from all parts. However, under certain conditions, the arc will hiss and become unsteady.

The conditions which produce hissing are: first, air currents, carbon impurities, &c.; second, shortness of arc. The following simple tests were devised by the writer during his investigations to locate definitely the part of the arc which is responsible for the hissing. Owing to the fact that hissing is always accompanied by unsteadiness, it was reasoned that it might be due to the changing of position of the vapour stream on either the positive or the negative carbon tips, and that the sound was caused by either the heating or cooling of the hot carbon, or by condensation of vapour on the negative.

An ordinary arc lamp was so fixed that one of the carbons could be moved in a horizontal direction without changing the length of the arc. It was then fitted with carbons, as shown in Fig. 2, using an ordinary carbon (burned to the regular shape) for the positive, and one having a flat end for the negative. If now an arc be struck between these carbons any horizontal movement of one of them will simply change the spot on which the vapour strikes the negative without influencing the positive in any way. This movement was made when the arc was burning silently, and the arc continued

* From the *Electrical World*

Digitized by Google

to burn silently during the movements, showing that the hissing was not due to condensation on the negative.

The carbons were then reversed, using a pointed one for the negative and a flat ended one for the positive, as seen in Fig. 3. In this case, of course, the positive crater will be obliged to change its position at every horizontal movement of the carbons. In this test every movement was accompanied with a hiss, showing that hissing is caused either by the sudden heating of the carbon to the boiling temperature of the crater, or by the sudden cooling of the boiling carbon formerly in the crater. The former theory seems most probable, for if the latter were true every arc lamp would hiss when the current is turned off; and this is not the case.

In the light of these experiments there is no difficulty in discovering the immediate cause of the hissing in short arcs. In looking at one (Fig. 4), we see that, instead of a stream of vapour coming

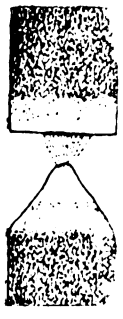

FIG. 3.—Upper flat carbon positive. Hissing caused by moving positive carbon about.

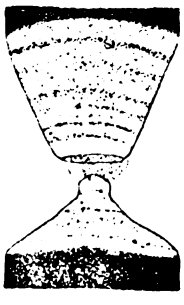

FIG. 4. The Hissing Arc.

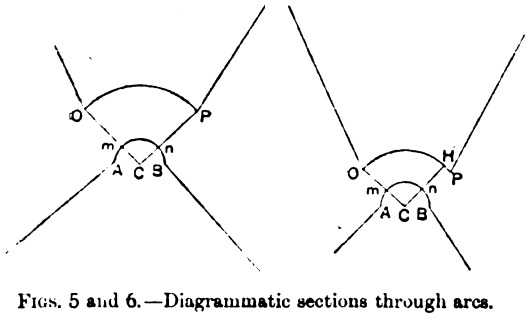
from the entire surface of the crater, there is a stream coming from only a part of the surface, and that the rest of the surface is at a temperature below boiling. The immediate cause of the hissing must be the fact that the boiling surface is constantly changing its position in the crater, and so constantly raising cool carbon to the boiling point.

The question still remains, Why does not the evaporation cover the crater surface in the case of the short arc as in the case of the normal arc? With the idea that the vapour stream might have a certain geometrical relation to the crater, a system of measurements was begun on normal arcs, using the same current and quality of carbon. The measurements taken were on the diameter of crater, depth of crater, length of arc and diameter of the knob on the negative carbon. Fig. 5 is a diagrammatic section through an arc. The figures from which this was drawn were obtained by measurements of normal 10 ampere arcs, using a good quality of soft carbon. O P is, of course, the crater, and A B the negative tip or knob; O *m n* P is the vapour of the arc. The striking thing about this diagram is that C is the centre from which *m n* and O P are described. This, however, shows what might be expected, namely, that the arc burns away the carbon, so as to keep all points at an equal distance from each other.



FIGS. 5 and 6.—Diagrammatic sections through arcs.

When it comes to the short hissing arc the measurements are more difficult—that is, the measurements taken on the normal arc will not amount to anything because the vapour stream, as was said before, does not come off from the entire crater, but only from a part. Of course, exact measurements of the area of evaporation could not be made, but by examining the crater after the current was turned off the area of the evaporation surface, just before it was turned off, could be noted by the peculiar appearance of the crater. By taking a number of measurements in this way, accurate enough results were obtained to draught a diagram shown in Fig. 6. It will be seen that the angles *m* C *n*, in Figs. 5 and 6, are nearly equal, and I think it is safe to assume that if O H, Fig. 6 (the area of evaporation in the short arc), could be obtained with absolute accuracy, the angle at C would be equal in both cases. The diameter of the crater O P is smaller in the short than in the normal arc, but there seems to be a point beyond which the crater ceases to decrease in diameter to correspond with the size of the vapour stream.

At this point the evaporating surface not being confined to a particular area, the arc begins to hiss. It is manifest that as the arc shortens, the crater will become more and more concave, and of course, its edges will necessarily become sharper. The heat of the arc tends to wear away the edges of the crater; but as the arc is shortened and the cavity becomes greater, the edges do not wear away fast enough to keep down the crater surface. In the short arc the heat at the carbon tips is less than in the normal, and this fact will help to keep the crater edge from wearing. I use the word "wearing" to cover the three processes, namely, evaporation, combustion, and disintegration, which consume the carbon outside of the crater. By evaporation in the crater I mean the active boiling which takes place there, though evaporation in general does not imply boiling. The decrease of heat which accompanies the short arc can be accounted for by the decrease of boiling crater surface.

The wearing of the crater edges will also depend on the quality of carbon used, and this is one of the reasons why some carbons will burn quietly with a much shorter arc than others.

The facts brought forth here do not pretend to be the results of any elaborate investigation, as they are no more than can be found out by anyone with the use of an ordinary arc lamp. At any rate, it is safe to say that there is much yet to be written and discovered about the common every-day direct-current arc.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.—TUESDAY, MARCH 29TH.

The Post Office and the Telephones.

On the motion for going into Committee of Supply on the Civil Service Estimates,

Dr. CAMERON rose to call attention to the relations subsisting between the Postal Telegraph Department and the telephone system, and to move:—

"That the Post Office system of granting licences to private telephone companies having resulted in the restriction of telephonic communication in this country, and a costly and inefficient service, this House is of opinion that, alike in the interest of the postal telegraph and the telephone service, the telephonic monopoly possessed by the Post Office should be worked directly and in connection with the Postal Telegraph Department."

After referring to the decision of Mr. Justice Stephen declaring that telephones were telegraphs within the meaning of the Telegraph Acts of 1863 and 1869, Dr. Cameron said he did not blame the Government for taking this course, because they were bound to protect, as far as possible, the ten millions of public money which they had expended in acquiring their telegraph rights. It must be taken into consideration that the Post Office telegraphs were at the present moment barely paying their working expenses, and that if telephonic competition was brought to bear against the telegraphs the Post Office must necessarily sustain heavy loss. But, on the other hand, if the Post Office authorities had acted in an ordinary prudent and businesslike manner, they would have been able to acquire all the rights of telephone inventors at a very reasonable rate, and thus have done a good stroke of business. The Government had already in existence a network of telegraph wires all over the country, and had suitable buildings and a sufficient staff at all the towns in the United Kingdom, and, therefore, if they had acted judiciously and with a due appreciation of the wants of the public, no private company could have hoped to compete with them. The Government, however, adopted a different course, and, instead of offering an equitable compensation to the telephone inventors, proceeded to set up some form of telephonic service themselves, and placed a crushing tax of 10 per cent. on the gross receipts upon the telephonic companies. The invention, however, was too valuable to be crushed by even such an exorbitant tax, and the telephonic service as supplied by private companies had extended in spite of that tax. In the meantime the 13 companies which were carrying on the service in the United Kingdom had come to a nice comfortable arrangement among themselves, which had resulted in the establishment of a great monopoly. The right hon. gentleman now proposed a policy the effect of which would be simply to consolidate and perpetuate the telephone monopoly which at present existed in this country. The result of the present state of things was the crippling of the progress of the telephone in this country. It had often been said that the telephone was the luxury of the rich; it had been made the luxury of the rich in this country by high charges and the high taxation of the Post Office. There was no reason why the use of the telephone should not be as general as the use of the telegraph, and why it should not prove much more useful to the poorer and the less educated classes of the community, who were not skilled in compressing their ideas into telegraphic form. When the public had once learnt the convenience of a good system of telephone communication they would not allow that system to be curtailed by the Post Office, and in self-protection the Post Office would be obliged to acquire entire rights over it. In 1880 the telephones might have been acquired for a few hundred thousand pounds; but the Post Office had continued putting off the inevitable step, and now, of

Digitized by Google

course, a very much larger sum would have to be paid. In asking the House to affirm his resolution he was asking it to assert that the Post Office ought to do something to justify its monopoly, and to relieve the community of a system of dual control which had in the past wrought so much mischief.

Mr. HENNIKER HEATON in seconding the motion, said the present was a great opportunity for the House of Commons to strengthen the hands of the Postmaster-General by insisting that the entire system of telephonic communication should be taken over by the Post Office.

Sir A. ROLLIT said it was to be regretted that the house had not received longer notice that the question of the telephones was to be brought forward, as there was no question of greater importance to the community generally. He had had the opportunity in the London Chamber of Commerce and elsewhere of ascertaining very clearly the wishes of the community in regard to the telephones, and he did not hesitate in the least to say that the general feeling was that, not only might the present telephone service in England be improved, but that it would bear no comparison with the development which it had attained in other countries Of course, at the present time a much larger capital sum would be required for the purchase of the telephones than would have been necessary some years ago. He thought that the Government ought to do for the community that which it could do better and more cheaply than individuals could do for themselves. He believed the telephone would be, if not cheaper, better conducted by the Post Office than by the telephone companies. The great objection was that the principle was being carried too far, and the impression was that the commercial community had been taxed for the benefit of the Post Office. This was the system against which protests were raised, and he thought a very decided protest would be raised against the appropriation of the returns merely to revenue. What the country wanted was the best and cheapest form, and that was why he supported the principle.

Mr. LABOUCHERE agreed with his hon. friend that monopolies had their duties, and in this case the question seemed to be whether the State should impose conditions on private companies or do the work itself. The hon. gentleman opposite had elaborated a very interesting Socialistic view of the duties of the State. He agreed with him generally, but he would point out that this was essentially a luxury of the rich. He remembered speaking to Mr. Raikes, who pointed out that personally he was in favour of taking up the whole thing; but the Treasury was not in favour of it, owing to the great expenditure, which, for, say, 200,000 subscribers, would require an expenditure of £8,000,000. Therefore it was a matter to be seriously considered. From the general statement the Postmaster-General made the other day, he felt the Bill met a very difficult question very fairly.

Mr. QUILTER said he felt it his duty, as a Director of the National Telephone Company, to reply to some of the statements that had been made. It was wonderful that the Company with which he was connected had developed to such an extent seeing the hindrances with which it had had to contend, and that it had to do all its business on sufferance. During last year 160 million messages, at a cost of under ¾d. a message, had been transmitted over the wires of the Company. That was on the basis of each question and answer being two messages. With regard to the question of inefficiency, and on the question of the trunk wires being unremunerative, he would point out that in one day between Liverpool and Manchester 42,000 messages were sent. Again, when the Company opened its exchange in Leicester in July, 1890, Her Majesty's telephone office had 130 subscribers. The Company's exchange had now been opened 18 months, and there were 275 subscribers, while the subscribers to Her Majesty's office, which was said to be so much better conducted, had fallen to 100. Yet the Company had not the same privileges the Post Office had. He could not understand how, in a free country like this, the man who was a licensee and paid 10 per cent. of his profits to the Government, should not be entitled to the same privileges of communication with the post-offices as the subscribers to Her Majesty's Post Office. In spite of all its dead weight, the Company had made marvellous way. He admitted that the service in London fell far short of what was wanted. But the Company would be perfectly able to do the work if the Post Office would delegate to them those powers which he humbly contended every licensee of the Government ought to possess.

Mr. GRAHAM said this did not appear to him entirely a question of profit and loss. In spite of the statements of the hon. member who had just spoken, he held that it was best for the community at large that all means of communication should be in the hands of the State.

Sir J. FERGUSSON said that in the statement which he had made a week ago the Government had desired to take the House completely into their confidence by explaining the scheme which they had in view, and the Bill which would be introduced would by no means cover the whole scope of that scheme. The matter was one which, if properly handled, would really conduce to the prosperity of the country. The course previously taken by the Post Office with regard to this matter might or might not have been the best one. Telephones might have been conveniently conducted along with the telegraphs, to which they were really akin; but that course had not been taken, and they had to deal with existing circumstances, involving a considerable amount of inconvenience. On the one hand, a considerable property had grown up in the hands of licensees of the Post Office, while, on the other, that system had failed to produce such an extensive use of this most useful invention as had been anticipated by the Government, and as had been the case in other countries. He thought that it was altogether unjust to hint that the object of the Post Office had been to stifle invention. No man, for instance, could have been more disposed to encourage invention than the late Mr. Fawcett. It was not correct to say that the Post Office had plundered at once the companies and the inventors. That was altogether a misapprehension of the facts of the case. It had been asserted that the Post Office had acted capriciously in the matter of granting licences. There had no doubt been different policies at different times, and applications had been dealt with under those different policies. But it could not be said that licences were granted too sparingly when they had been granted to 13 companies. In determining now not to grant licences in a wholesale way, the Department was, in his opinion, quite right. Nothing could be more erroneous than the suggestion that the possession of the trunk lines by the Government would be detrimental to competition. It was, on the contrary, the very circumstance likely to encourage competition. A new company with no trunk lines could not compete with an older company that had trunk lines. It was the object of the Government, after having established trunk lines, to connect together the local exchanges in every part of the country. Whilst the Government proposed that the companies should be allowed, by becoming connected with the Post Office, to achieve a new development in their industry, they only intended to grant the privilege to companies that were ready to join in a system of free and unrestricted communication. Complaint had been made of the royalties which companies were made to pay, but the sum paid had never exceeded £46,000 in a year. This could hardly be deemed an extravagant figure when it was borne in mind what dividends the National Company was paying. The great development of telephonic communication in Paris had been alluded to. Under the Paris system there was no restriction upon free communication with the Post Office, and it was the very system which the Government desired to establish in this country. Having acquired the trunk lines and mains, the Government would be able to promote free competition and the commercial development of telephones. They were in possession of a telephone between London and Paris, which was doing very satisfactory work. They had found it necessary to establish a second metallic circuit; there were 120 conversations a day, and the charge made was 8s. for three minutes' conversation. He anticipated that, when the Government should have completed their system, there would similarly be constant conversations between all the great towns in England. The Post Office possessed the right of laying down underground wires in towns. These wires they would let to the Companies for the development of their exchanges, but this arrangement as to mains was not essential to the scheme. The desire of the Post Office being to facilitate the work of the companies' exchanges, they were ready to undertake the laying down of wires in towns. He recognised that this country owed much to companies, and it would, in his opinion, be most short-sighted and ungrateful to treat all companies as if they were leviers of blackmail, or sharks, or monopolists. The Government had no desire to restrict unduly the operations of the companies, which they hoped would conduce to the public service; and, therefore, they were willing to place a liberal interpretation upon the agreement as far as the areas within which the companies might lay their main wires were concerned. The hon. member for Canterbury had expressed his desire that the Government themselves should take over the telephones, and, following the example that had been set with respect to the telegraphs, should make them national undertakings. He was afraid, however, that such a proposal would be a very far-reaching one. He did not suppose that in order to carry out a telephonic system anything like the large capital that had been invested in the telegraph system would be required; but, at the same time, the House would hesitate before it authorised the Government to largely increase its Post Office capital or the number of people in the Post Office employment. He thought that it was undesirable that there should be a direct employment by the State of a great number of *employés*. He submitted that the Government had acted prudently in endeavouring to restrict the number of persons in their employment, as long as the public service was efficiently provided for. In these circumstances the Government had resolved not to acquire the capital of the companies, but to permit them to continue to carry on the services under their licences. Turning to another point, it was quite evident that there would be a number of telephonic districts which would not pay if they were in the hands of the Government. Of course, if it were desired that both the telegraph and the telephone systems should be carried on by the Post Office, irrespective of the amount of profit revenue to be derived from them, the public want could be easily provided for. No doubt in certain of the Australian colonies the Government undertook to work the telephone service as they undertook to work the railways; and, perhaps, in an undeveloped country it was desirable that the Government should undertake many matters which could be better managed in this country through private companies In this country the work could not be done as cheaply by the Government as it could by private companies, and he did not think that even in Australia the undertakings had been commercial successes, it having been found necessary in that part of the world to reduce the accommodation on the railways and to increase the fares. It was for these reasons that Her Majesty's Government had not thought it prudent to undertake this great additional service, and had decided to leave the working of it to private companies. Her Majesty's Government, in these circumstances, felt bound to oppose the motion of the hon. member. With regard to the profit revenue that was likely to be derived from supplying the public demand for a telephonic service, it was a remarkable fact that an extension of the service beyond a certain point involved a reduction of revenue. A Director of two American telephone companies had informed him that it sometimes took three years of the amount of a subscription to pay for a fresh installation, and that it was not until the lapse of that period that any profit began to be derived from the particular subscriber. These things ought to operate as some excuse for the companies not having brought the cost of their service within what some would call reasonable bounds. He would, however, try to improve the system, and he was bound to say that in a short time telephone communication would proceed at a rate hitherto unknown. There were one or two points upon which there was some misapprehension which it was desirable should be removed; and if he opposed the motion of the hon. gentleman, he thought it right to show that the offer of the Government was not illusory, and that they had the

Digitized by Google

same object as the hon. gentleman had at heart. They proposed that telephone communication should be established as widely as possible between one part of the country and another. There was no reason why new companies should not be formed to create new exchanges. He had not the least doubt that in a very short time we should hear of the establishment of new companies and new exchanges, although the existing companies could establish new exchanges with special advantages. And behind the companies was the power of the Government to erect telephone exchanges. Undoubtedly, if people desired to have telephone exchanges in their towns, and could not conveniently establish companies of their own, or if the existing companies did not supply their wants, the Post Office would come in as at Newcastle and Hull and supply telephone exchanges and perfect the system between towns. The safeguard for the taxpayer was that any profits derived from this action of the Government would be in the hands of the Post Office and would go to the direct benefit of the revenue. No part of this policy required the sanction of Acts of Parliament; all these things were entirely within the existing powers of the Government. They were a new development of the system already pursued by the Post Office under the authority of Her Majesty's Government. But undoubtedly the House of Commons would have to be consulted with regard to the mode of carrying out the system; and as there would be an increase of the Post Office vote *ad hoc*, Parliament would be asked to endorse the action which might be proposed. The Government intended to relieve the cost of the heavy obligations which rested on the companies for way-leaves. He believed and he hoped that competition would not be diminished, that profits would not be decreased, and that all would share in the advantages of the extension of the system which was so much desired, and which he was satisfied would place this country in as full possession of telephonic invention as any country in the world.

Mr. PROVAND said that the telephone had become the monopoly of the Government some years ago, but they had licensed 13 companies, out of which only three or four survived at present. The Post Office had the option of buying up these companies only every seven years, and the next opportunity they would have would be six years from the present time. The question had been actively before the Post Office for the last 18 months, and some measure ought, before now, to have been submitted for the consideration of the House. He could not vote for the motion of the hon. member for the College Division. That motion meant that the Post Office was to start telephonic exchanges in opposition to those of the companies to whom licences had been issued; and that would not be equitable, because the companies already paid a 10 per cent. royalty to the Post Office. If the motion had not that meaning, it meant that the Post Office was to buy up the telephone exchanges, and he could not support any such proposal unless it were accompanied with the terms on which the purchase was to be made.

The CHANCELLOR of the EXCHEQUER said that as the matter under discussion so deeply concerned the finances of the country, the House would perhaps allow him to supplement the statement which had been made by his right hon. friend. The Executive Government and the Civil Service might well congratulate themselves on the fact that the House was so very ready to trust a vast new business to the management of a public department. It might have been thought, in view of the many complaints which had been made of Post Office administration, that any proposal to extend the operations of that department would have been severely criticised by the House. But it was evident that, in spite of these complaints, the House placed considerable confidence in the Post Office, and was not afraid to give into its hands a new and increasing business. But that principle ought not to be pushed too far; and he was not prepared to accept in an indefinite degree the constant placing of new duties upon the State. The Postmaster-General was at present at the head of an army of 100,000 men; and no one ought to look with a light heart on the unlimited increase of such a vast army. The House ought to be extremely careful before asking the Government to put its hand to new work of such vast dimensions. It was not a Post Office question, so much as a question of public policy. The scheme of his right hon. friend would show the House to what lengths the Government were prepared to go. The hon. member who had spoken last had raised two very pertinent questions, in referring to the alternatives of buying up the telephones or of competing freely with the present companies. Of course it would be impossible for the companies to compete with the Government; and if the Post Office took action on its own account, it would be necessary to make some money payment to the private companies. He remembered the purchase of the telegraphs, and he shuddered at the recollection of the enormous price which the Government had to pay for them. The public at that time were determined that the telegraphs should be taken over, and the Government could not proceed with sufficient caution. He did not wish the Government to be placed in a similar position with respect to the telephones. They offered to the public a plan which combined the simplicity of Government control with the expansion to be expected from private enterprise. His right hon. friend had explained how the trunk lines would be taken over by the Government, leaving to the localities the working of the local exchanges. If that were done, he believed that the public would be better served than if the Government were to take over the entire system; because there would be a competition in the localities to serve the public as well as it could be served. The attitude which the Government would then take up towards the local authorities would insure that if a town was badly served there would be another Company to meet the want; while if the town were sufficiently served there would not be the inconvenience of multiplying wires and taking up the streets which was inevitably attendant upon the establishment of competing companies. It had been suggested that the local authorities themselves might be willing to undertake the telephone business; and he saw nothing to contradict the Government's policy to such a proposal. If there were a town in which a telephonic system had not been established, and in which the local authority wished to undertake the system, there was no reason against such a course, the communication with the rest of the country being established by the trunk lines in the hands of the State. It was absolutely necessary that the Government should take the trunk lines into their hands. If that were not done they could not have that competition which it was desired they should secure. While the National Company had a monopoly it was impossible for the other lines to compete. A telephone circuit was only half useful unless it was put into telephonic communication with the rest of the country; and unless that were done the people of a locality not in communication with the whole of the country would be only half served, and therefore it was why in one sense the Government would have to take the trunk lines into their own hands as a means by which to secure free trade. On the other hand, they wished the local authorities to exercise supervision. He did not know whether the House was aware of the powers which the Government possessed in this matter, but the powers rendered it unnecessary to introduce a fresh Bill. In the licence which was granted it was clearly provided that nothing in the licence should affect the right of the Postmaster-General to establish, maintain, and work any system of telegraphic communication as he shall in his discretion think fit. Therefore, the licensees had been warned that the Government retained the power in their hands. He thought that it would be evasive of the spirit of the licence if during the continuance of the licence they took the whole of the telephonic arrangements into their hands to the detriment of those who on the faith of the licences had been extending the system up to the present moment. This was the compromise they offered, and he thought they had gone a long way. They had great confidence that they should be able to work the system with great elasticity, though he was fearful of the effect of the telephone on the telegraph revenue. But they had come to the conclusion that financial considerations ought not to prevail against the extension of the telephonic system, which was considered by the public to be a convenience.

Mr. ROBY hoped the mover of the resolution would press it to a division. He thought the Chancellor of the Exchequer would find that in the long run he would have to go a step further, and that the only difference would be that the interest they would have to purchase would be much greater than it was now. As the telephones were competing with the telegraphs it would be better to make a good mouthful of the business.

The House divided, and the numbers were—

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, April 1st.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Smoking Concert at St. James's Hall Restaurant.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Motion of the Ether near the Earth." By Prof. Oliver Lodge, F.R.S.

SATURDAY, April 2nd.

INSTITUTION OF CIVIL ENGINEERS.

6.30 p.m. Annual Dinner of the members, in the Town Hall, St. Martin-in-the-Fields, Charing Cross Road.

MONDAY, April 4th.

SOCIETY OF ENGINEERS.

7.30 p.m. "Electrical Traction and its Financial Aspect." By Stephen Sellon; conclusion of discussion. A Paper will afterwards be read on "The Application of Electricity to Hoisting Machinery." By Reginald Bolton.

TUESDAY, April 5th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary meeting. Paper to be read: "The Sewage Farms of Berlin." By H. Alfred Roechling, Asoc. M.Inst.C.E. At this meeting the monthly ballot for members will be taken.

WEDNESDAY, April 6th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "The future Trade Relations of Great Britain and the United States." By Robert McCornick, Resident Commissioner for Great Britain from the World's Columbian Exposition.

THURSDAY, April 7th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. "Load Diagrams of Electric Tramways and the Cost of Electric Traction." By A. Reckenzaun, Member. Continuation of discussion.

FRIDAY, April 8th.

PHYSICAL SOCIETY.

5 p.m. Ordinary meeting. Papers to be read: (1) "Note on a Law of Colour in its relation to Chemical Constitution." By William Akroyd. (2) "On the Construction of a Colour Map." By Walter Baily, M.A. (3) "A Mnemonic Table in connection with Electrical Units. By William Gleed, M.A.

ROYAL INSTITUTION

9 p.m. Evening Discourse: "Electric Meters, Motors and Money Matters." By Prof. W. E. Ayrton, F.R.S.

THE LANE FOX CASE.

It is not until an important Patent Case has dragged on through the Courts of Chancery and Appeal and the House of Lords that it can be said to be over; and even this routine may be varied by the ordering of a new trial. But we are permitted by custom to comment upon it after judgment has been delivered, whether the usual course in such important cases is proceeded with or no. The judgment, which was delivered on Wednesday last, went against Mr. LANE FOX, in the first place on the ground of disconformity between the provisional and the final specifications as amended. It was decided that the system described in his patent was impracticable; that during the thirteen years which had elapsed no practical examples of its use could be pointed out; and that an intelligent workman could not successfully carry out the instructions without experiment and further invention. The "earth" was the only point which was given in favour of the plaintiff.

There are four points of view from which the Lane Fox case may be regarded,—the historical, the scientific, the moral, and the commercial. Historically, the use of the term "earth," the various attempts to use earth return in practice, and the details of the earliest examples of incandescent lighting, were interesting; but the important feature, and one about which much more might have been told if it had entered directly into the recent lawsuit, was the discovery of the parallel system of distribution. It cannot be denied that in the interval between the filing of Mr. LANE FOX's provisional specification, 3,988, 1878, and of the final, the whole assembly of scientific men who gave evidence on the practicability of electric lighting before the Select Committee of the House of Commons were intent upon arc lighting. It is all very well to say that there were no glow lamps worth considering, and that if there had been "there would have been no difficulties." The recollection of COLUMBUS and the egg is irresistible. Of course, the connection of circuits in multiple

arc, as it was called, was well known to telegraphists; but the idea of low-resistance mains with a constant difference of potential, and high-resistance glow lamps, was conceived by LANE FOX as a practical system, and proved to be so by him, in spite of the incredulity of dozens of scientific authorities who thought that the whole current would run by the shortest route through the first lamp. Not only was it proved to be practicable, but the whole of our present glow-lamp distribution is the result. WOODWARD and WERDERMANN had suggested parallel working; but Mr. LANE FOX did something more: he showed that the principle was sound and practical. But a principle cannot be patented. On page 290 of the first volume of the present series of *The Electrician*, Nov. 9, 1878, the Werdermann lamp is illustrated and described: "The method of dividing the lights is that known and used to so great an extent in every branch of electricity, viz., 'the multiple arc system.'" But we find that early in 1879 the following statements were made at a lecture at the United Service Institute: "The ease with which a wire can be maintained incandescent has led many to believe in the possibility of the extreme subdivision of the light. There is, however, no difficulty in showing that this hope is quite inadmissible, according to our present knowledge . . . It is easily shown that in a circuit where the E.M.F. is constant and we insert additional lamps, then, when these lamps are joined up in one circuit, *i.e.* in series, the light varies inversely as the square of the number of lamps in circuit; and when joined up as in multiple arc, the light diminishes as the cube of the number inserted. Hence the subdivision of the light is an absolute *ignis fatuus* . . . Although the extensive subdivision of the light must be ranked with perpetual motion, squaring the circle, and the transmutation of metals, yet no one will say it is 'impossible;' but all must say 'not yet.'" So anxious were our eminent electricians to shelter an ignorant public from the chimerical schemes of inventors! A collection of the criticisms of the day on incandescent lighting would be very amusing. One serious objection was based on the C^2R law; we remember hearing this enunciated at the time, but it is as difficult as a dream to reconstruct from memory The recent trial has not shaken Mr. LANE FOX's claim to the discovery of the practicability of parallel distribution at constant pressure, but, on the contrary, has established his position on surer grounds.

It is difficult to point to any one prominent scientific feature in this case. The weakest point of the plaintiff seems to have been in the liability of secondary batteries to sulphation unless occasionally charged up to 2·5 volts per cell. It was rather rash on the part of his witnesses to suggest that any useful charging can be effected with a one per cent. increase of pressure. The questions at once arise—one per cent. above what? and how is the one per cent. measured? Can it be done except on a laboratory scale? From one point of view this was fatal to the plaintiff's case; but the ATTORNEY-GENERAL put forward the most ingenious argument that, while it is desirable to keep the batteries in health, and while recent knowledge has shown how this may be done, nobody suggested that the cells act differently when they are in that condition, and that it had no relation to the use of batteries either as reservoirs or as regulators. As soon as it was known that batteries ought to be occasionally charged up to 2·5 volts per cell, the use of switches for altering the number of cells was an obvious improvement. Experiments were carried out during the trial by Mr. LANE FOX's friends to show that charging and discharging could be carried out within the Board of Trade limits of variation of pressure; but the results were not put in, and wisely, we think, since the necessity for thorough charging ought to be frankly admitted. The experiments, however, were in themselves interesting; and we hope, on a future occasion, to publish the results. Of the scientific aspect of the earth-plate question there is little to be said. The rather hasty guess of Prof. PERRY is more pardonable than the suggestion that a coil of bare wire thrown into a river would form a good earth-plate. Its effective area would of course be about the same as a disc of metal of the same diameter. Still more misleading was the twice repeated tale that no current whatever could be induced to pass through an earth return; for the Judge could not be expected to understand, unless the point had been carefully explained, how the fact that in both cases a series-wound dynamo was used, completely explains the failures.

It was not the business of the Court to consider the moral side of the question. This ceased indeed to be anybody's business as soon as the Lane Fox Electric Company began to take legal proceedings. When Mr. LANE FOX first employed a firm of Westminster engineers to negotiate with the Brush Company for the re-assignment of the patent, no exorbitant demands were contemplated. The inventor of the application of the system of parallel working at constant pressure, in combination with secondary batteries, was, we think, morally entitled to some recognition and remuneration, in spite of the fact that he assigned away his legal rights to an apathetic or adversely interested company. The suggested sum of £300 a year for two years from the Kensington Company, and a like sum from the others, would not have been oppressive; and if private consumers had been let alone and if straightforward arrangements had been made through a solicitor, it is not improbable that the affair could have been settled. Mr. CROMPTON on the other hand has something to say. He acknowledges Mr. LANE FOX's early inventions; and admits, we believe, that our modern methods are the outcome of them. But the present system, as exemplified by the usual arrangement of machinery and apparatus, has not grown of its own accord; it has been the fruit of years of hard work, of thousands of pounds spent, of continual experiment, and of accumulated experience. Mr. LANE FOX, in Mr. CROMPTON's view, has contributed to none of these, while he claims that the result is his; and that the elaboration, to which Mr. CROMPTON justly points with pride, consists of more or less useless and adventitious complications. Mr. LANE FOX's moral claim and perhaps his legal case would have been strengthened by the acknowledgment of the improvements which have been brought about since he ceased to concern himself with secondary batteries.

The mention of the terms which were asked by the Lane Fox Electrical Company brings us to the commercial point of view. At a meeting held in July, 1890, it appeared that the royalty asked from supply companies was one farthing a unit for the two remaining years of the patent, amounting, in the case of the Kensington and Knightsbridge Company, to £300 a year. Some such sum as this might fairly have been paid; but 1s. 6d. per lamp was being asked from owners of plant for private houses, and 2s. 6d. per lamp for clubs, hotels, &c. This was not only a much more serious demand, but it was peculiarly vexatious, since such users could not be expected to know anything about the existence of the patent, or even of the talented inventor himself. It is doubtful whether previous to the opening of negotiations after the conclusion of the litigation between the Brush and the Edison-Swan Companies, there were twenty persons in this country who knew that the patent was still alive. Such resuscitations are very rare, or there would be ample justification for an extension of the statute of limitations to such cases

Digitized by Google

However much the industry may have been indebted to Mr. Lane Fox, his equitable right to demand oppressive royalties has been greatly diminished by the absence, during the past ten years, of any demand for payment, or warning that a claim might some day be made. Royalties on various scales were proposed from time to time, and these will be found recorded in the earlier numbers of our twenty-fifth volume. During the negotiations, the annual royalty demanded from the Kensington and Knightsbridge scapegoat rose to one penny on each unit sold, equivalent to some £1,200 on last year's output. For the suggestion of this exorbitant sum we believe Mr. Lane Fox has to thank his commercial advisers. It was this that compelled the supply companies to form a Defence Association, and it was this that has led to the waste of time and money on litigation.

The subsequent patents of Mr. Lane Fox are full of the development of details, and show a wonderful foresight which has been recognised both by the opposing counsel in this case and by the Judge. But some of these have lapsed, and others were bad and would have needed a serious amount of pruning by disclaimer. No. 4,043 of 1879 contains amongst other suggestions the method of heating water by an enamelled wire placed at the bottom of the vessel, the very plan now adopted in the electrical cooking demonstrations at the Crystal Palace. But electric lighting was in its infancy in those days, and it was practically impossible to protect so wide a system as that of parallel distribution except by a vast number of patents for details; and details such as those on which important patent cases have been won are rarely to be found in the patents of Mr. Lane Fox. It is perhaps well that broad patents are difficult to secure, and that principles cannot except in very rare instances be patented. Monopoly in such cases generally offers a serious impediment to trade. To restrict the facilities offered by the Patent Office would be to restrict the exercise of inventive faculties; but principles are discovered, not invented, and the making of discoveries cannot be checked. Unlike invention, discovery needs no artificial stimulation; when the time is ripe for a new scientific revelation it will, in the nature of things, be made, if not by one particular man, then by some other. In 1878 the world was not ready for parallel distribution. To Mr. Lane Fox belongs the honour of the discovery, and essential parts of it are the high-resistance filament and the constant potential.

REVIEWS.

"Modern Practice of the Electric Telegraph." By F. L. Pope. (New York: D. Van Nostrand Company.)

If there is any advantage in a new work on a subject already flooded by text books, it may exist in a more lucid manner of treatment, or in the pieces of practical experience the author gives by way of leading his readers on step by step. We find nothing beyond the mere text book style in the first six chapters, treating on the Sources of Electricity, the Theory of Quantitative Electrical Measurement, the Laws and Conditions of Electrical Action, and the Laws of Electro-Magnetism. One oasis appears in the fifth chapter, where directions are given how to construct a tangent galvanometer, but this the author gives as "taken in part from S. R. Bottone's 'Electrical Instrument Making for Amateurs.'" On page 61 we find the words: "From the above explanations and examples it will be seen that a standard galvanometer may be constructed from which it is always possible, knowing the force of the earth's magnetism, to determine the value of any electric current in amperes." Looking back for these explanations we find nothing of the kind of information the student wants. He would want to know whether it was worth his while to start making such an instrument; and, if so, some directions as to proper proportion of size of coil, size of wire, and size of needle, &c., and some hints as to how to start about it, and what to do with it when completed. Finding no "explanations," we turn to the theoretical "examples," and find that, "given the number of turns, and the mean radius of the coil of the tangent galvanometer, the observed deflection, and the horizontal force of the earth's magnetism at the place of observation to find the current in amperes," the following rule must be applied:—"Multiply together the mean radius in inches, the tangent of the deflection, and the magnetic force of the earth in dynes, and divide the product by the number of turns in the coil. The quotient is the current in amperes." This can only be characterised as the most careless and misleading, not to say ignorant, treatment of the subject. To put inches instead of centimetres after the disquisitions on pages 36 to 38, on the C.-G.-S. system of units, may be passed over lightly in comparison to the error of putting the C.-G.-S. unit of current as equivalent to one ampere. But the case is even worse when the constant 2π is omitted, for it leaves the statements, rules, and examples absolutely devoid of reason. It is a relief to turn to chapters VII., VIII., and IX. on telegraph circuits, the equipment of American telegraph lines, and testing telegraph lines, where the author is apparently more at home, and where some good practical data are given as to the working of lines which the American telegraphist should find useful. But the author fails, even here, to give any precise details. The Blavier test, given on page 202, is dismissed by saying that "it presents some difficulties for the reason that the resistance of the fault is usually variable." There is nothing original in the illustrations, which are wearying to look upon, so often appearing and re-appearing in different works; and, with the exceptions named, the book can only be regarded in character as general and superficial.

"Electricity up to Date." By J. B. Verity. (London: F. Warne and Co.)

A rather rash title has been chosen by Mr. Verity, who thus lays himself open to any amount of criticism; but the little book is accurate enough for the purpose, which is to add one more to the host of popular books on the subject. With a mistaken modesty, the author has omitted all reference to cost of wiring and fittings and price of electric supply, matters on which he is so thoroughly competent to deal, and on which his opinion would be worth having. The scientific part is rather weak, and contains such statements as the following: "The points of the carbon rods become highly incandescent, and, in addition, the space between them is filled by a sort of flame or cloud of particles of white hot carbon. From these particles of incandescent carbon, forming as they do one dazzling mass of brilliancy, more light is emitted than from the points of the carbons themselves." He reproduces the illustration which appeared in Deschanel's book some fourteen years ago, and has done good service in more than half the books on electric lighting which have been published. It is hardly necessary to say that no such cloud of particles appears in the excellent illustration. A good summary of the supply companies is given, together with a coloured map of the London districts.

The Occlusion of Hydrogen by Nickel.—In *Il Nuovo Cimento* (Vol. XXV., p. 222) MM. Bellati and Lussarra describe some interesting investigations carried out by them in connection with the occlusion of hydrogen by nickel. The experiments were carried out with nickel wires used as negative electrodes of a voltameter. After a current had been passed through the voltameter for 200 hours one of these wires had absorbed about 100 volumes of hydrogen. The occluded hydrogen was not given off freely; on the contrary, the wires became oxidised on exposure to the air. While the process of occlusion was going on the wire elongated in eleven days by ·000036 of its length, so far as could be ascertained. The resistance of the nickel augmented as occlusion went on, its temperature coefficient diminishing.

MATHER AND PLATT'S ALTERNATOR.

Messrs. Mather and Platt, of the Salford Iron Works, Manchester, have recently constructed two large alternate-current machines for a central station for lighting the borough of Redfern, Sydney, New South Wales.

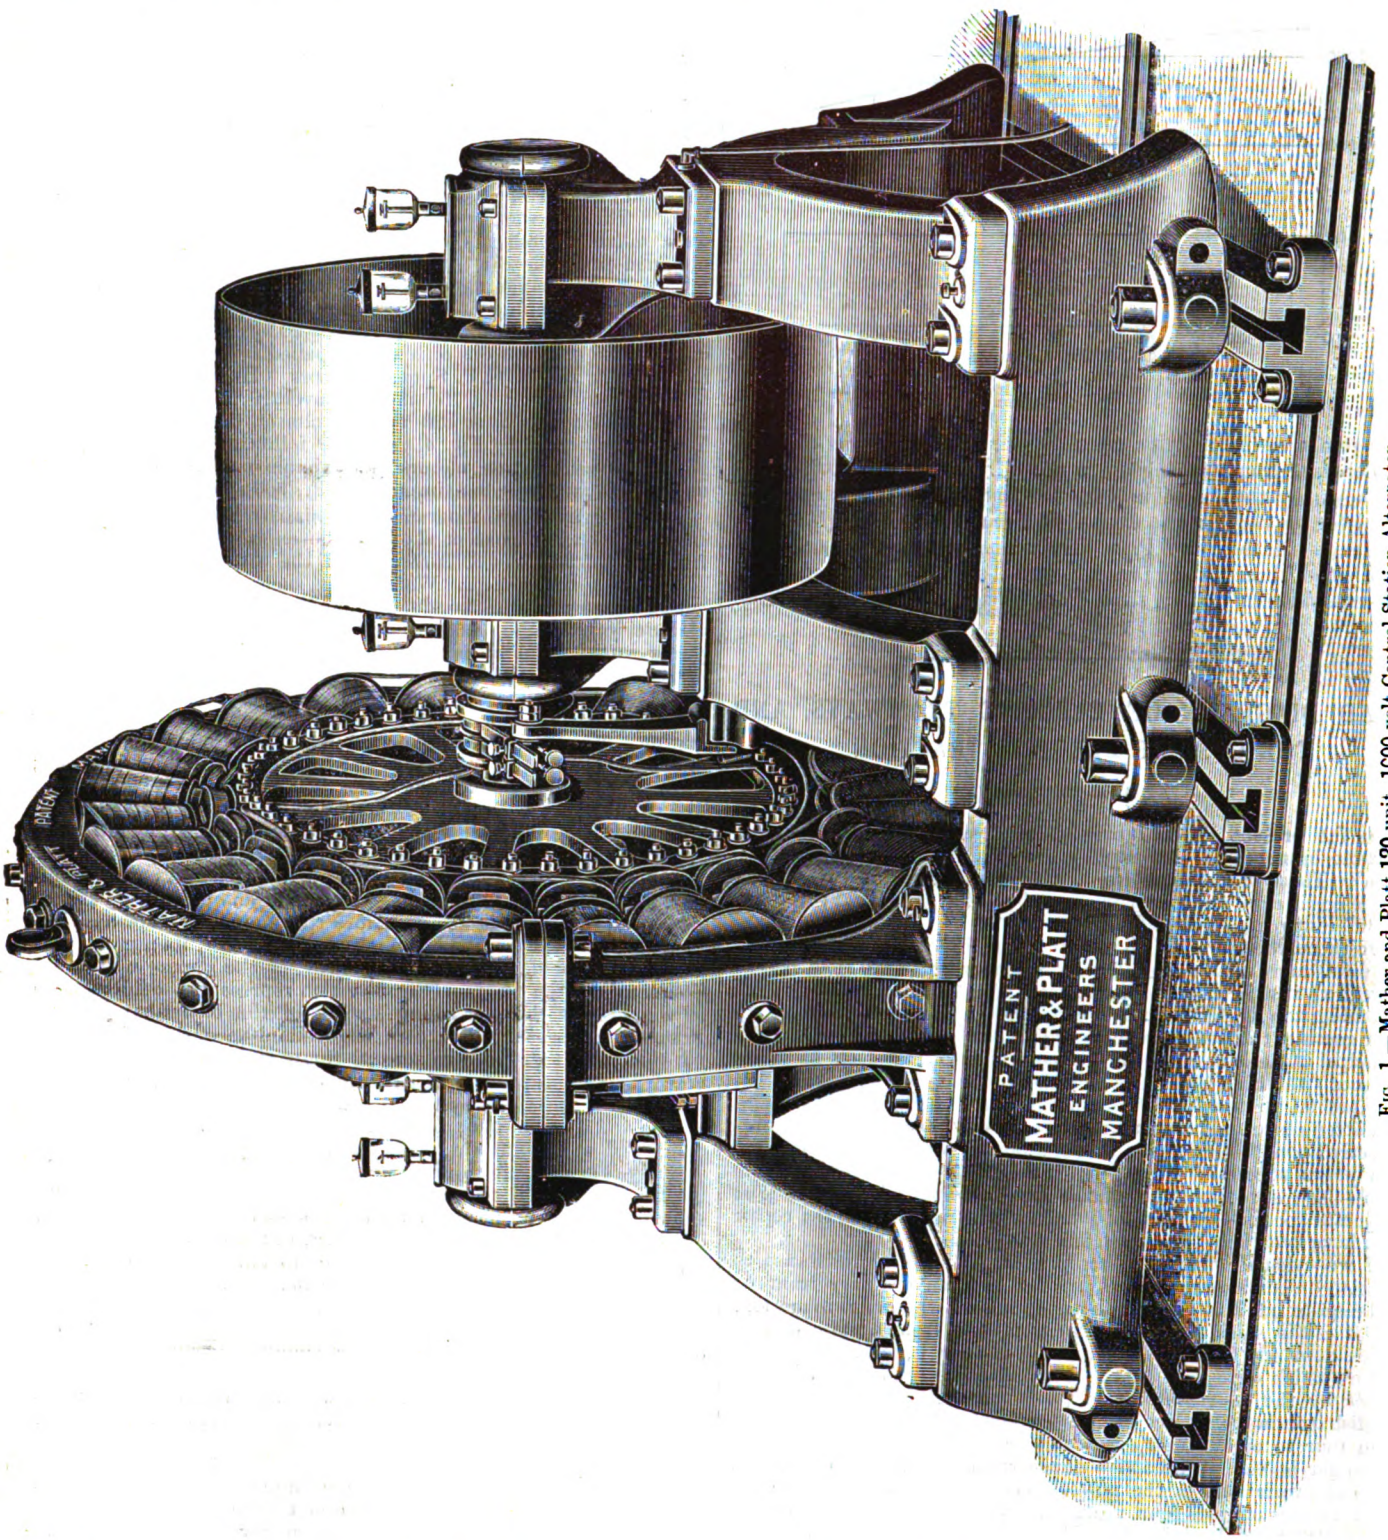

FIG. 1.—Mather and Platt 120-unit, 1000 volt Central Station Alternator.

As is the case with most alternators in which the cores of the armature are of iron, the armature revolves, and the magnets are fixed. The magnets are of wrought iron, and arranged round the armature exterior to it, and are attached to a massive cast-iron ring, which forms the yoke connecting the limbs. The attachment is so arranged that any of the magnet cores can be removed without disturbing the remainder or taking out the armature. The yoke ring is made in halves, so that the upper part may be lifted to allow of the easy removal of the armature.

The armature itself is constructed of two plates or discs keyed on to the shaft, between which the armature cores are held by bolts. As is the case with the magnets, any section of the armature can be removed without disturbing the remainder. Apertures in the discs allow free ventilation of the interior of the armature.

The machines in question (*see* Fig. 1) are manufactured under the patents of Dr. John Hopkinson and Dr. Edward Hopkinson, and are designed for an output of 120 kilowatts, at 1,000 volts, when running at 400 revolutions per minute. There are 24 poles, so that the number of reversals is 9,600 per minute, corresponding to a frequency of 80. The resistance of the magnets is 16 ohms, and of the armature 0·11 ohm, and the exciting current is 5 amperes.

Digitized by Google

Careful tests have been made on the commercial efficiency of a similar machine of somewhat smaller size by driving it from a motor of known efficiency and absorbing the power generated by the alternator in a non-inductive water resistance. These tests show a commercial efficiency of 92 per cent. The fall in

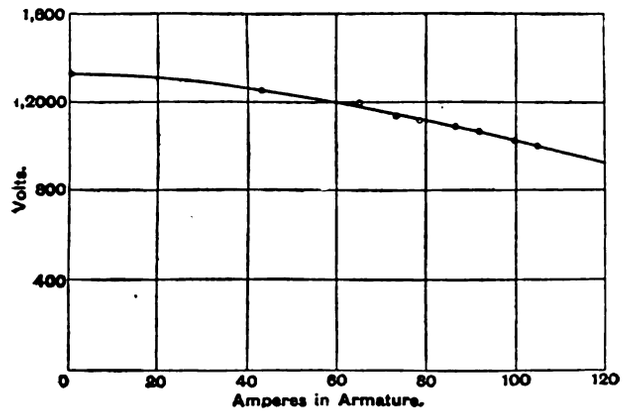

FIG. 2.—Curve shewing fall of volts as load increases.

electromotive force with a constant exciting current as the load is increased from nothing up to the full current of 120 amperes is shown by the curve in Fig. 2. In practice this is compensated for by varying the exciting current.

Messrs Mather and Platt have constructed a considerable number of these alternators for central-station work, and make the machines in various sizes, from 16 kilowatts up to 200 kilowatts.

LOAD DIAGRAMS OF ELECTRIC TRAMWAYS, AND THE COST OF ELECTRIC TRACTION.*

BY A. BECKENZAUN.

In the present Paper I propose to draw attention to two important branches of this rapidly growing subject, "electric traction." These branches relate to the energy consumed in propelling electric cars, and the commercial results of several tramways in different parts of the world.

Of the errors into which the pioneers in electric traction fell none was more serious, and I may say more general, than that of providing insufficient motive power. The early motors were all too small, too lightly built, and consequently were not durable. In spur gearing, the double-reduction gear has been abandoned by the principal American firms on account of its great cost of maintenance; the high speed at which the motor pinion had to run was detrimental to the life of the mechanism. A reaction has set in, and attempts are being made to drive cars by placing the armatures directly upon the axle. It is questionable whether this method will prove successful in the long run. But the single-reduction gear—that is to say, one pinion and one spur wheel running at moderate speeds—appears to give excellent results, and the repair bills have been largely reduced in consequence.

If we calculate from the accepted coefficients of resistance to traction on common tram rails, we find that an ordinary tram-car will require but 3 to 4 H.P. for its propulsion when once in motion. But it is the setting of a vehicle in motion from a state of rest which demands the greatest amount of energy; and the electric motors which were built in the early days were soon knocked to pieces by the enormous strain put upon them on starting. On English tramways, it has been computed, a tram-car has to stop from four to eight times every mile, according to the amount of passenger traffic. With a view of ascertaining the exact conditions as to the variations in the power consumed on an electric car, I made a series of tests four years ago with an electric car in the public streets of Philadelphia. Fig. 1 represents a portion of a diagram obtained from careful readings with reliable instruments. The whole trip lasted 71 minutes, but the diagram (Fig. 1) represents only the first 19 minutes. Readings were taken and recorded every three seconds. The maximum current, it will be observed, reached at times 120 amperes. This occurred when starting on curves and gradients. Frequently it dropped to zero, and, in fact, these gaps, representing periods when no current was used, gave, on being added up, 45 per cent. of the total. The car contained 84 storage cells weighing 3,400lb., and it carried an average of 26 passengers. The aggregate weight propelled was 7 tons. The distance covered during the entire journey was 7 miles, giving a mean speed of only 6 miles per hour; and this had to be maintained on account of the horse cars which ran on the same line. Averaging the current consumed, we find it to be 31 amperes. The maximum E.M.F. was 160 volts, and the mean 157 volts, giving an average of 6·52 E.H.P. used by the car motor. The maximum current of 120 amperes into the minimum E.M.F. of 140 volts would give 22·5 E.H.P.; but this occurred only nine times during the journey, and each time but for a second or two. Currents of from 60 to 100 amperes were recorded more frequently.

The next three diagrams are exceedingly interesting, as they represent the working of three different systems of electric cars on an overhead conductor line at Des Moines, U.S.A. These tests were made on the same day, over the same length of track, with the same number of passengers carried, and the same kind of car body The cars were operated by the same man, and the readings were taken by officials of the tramway company. Fig. 2 was obtained from the car fitted with two 15-H.P. Thomson-Houston motors. The maximum current at any time was 75 amperes, the mean 22·4, dropping at times to zero, while the E.M.F. varied between 360 and 520 volts on a run of 20 miles. Fig. 3 gives the curves from observations on a car propelled over the same distance by means of two 15-H.P. Sprague motors. Here again we observe a maximum current of 75 amperes, average 25·95 amperes, with E.M.F.'s varying from 320 to 560 volts at the motor terminals. Tests, represented by Fig. 4, gave the following results with two 15-H.P. Westinghouse motors:—Maximum current, 95 amperes; mean, 31·3 amperes; maximum E.M.F., 560; minimum, 360.

I could give more diagrams of a similar kind, but these will suffice for the purpose of showing the enormous and remarkably frequent fluctuations of current, and the attendant rise and fall of the energy consumed. With several such cars running on a line with overhead or other conducting medium for the transmission of electricity from the generating station to the moving cars, the peaks would occur at more frequent intervals, filling the great gaps in proportion to the number of cars running simultaneously. Little reliance, however, should be placed upon the possibility of obtaining even a moderately constant load at the generating station. From numerous experiments, I have found that it takes about 20 seconds to bring a tram-car from rest to its normal speed; during this period the current drops gradually from its maximum, due to the ohmic resistance of the circuit, to a value corresponding with the load upon the car motor at its normal speed. The stoppages on tram lines with much traffic are so numerous that it will often happen that a large percentage of the cars start simultaneously, when for a moment the engines and dynamos have to exert their utmost power, and before the engine governor has time to act the current may be down again at, or below, its normal.

I am indebted to Mr. Gibson Carey, of the Thomson-Houston Company, for the diagram (Fig. 5) which represents the fluctuations of the load at the generating station of the Roundhay Electric Tramway at Leeds. Five cars were simultaneously on the line, yet the current dropped to zero 20 times within the space of one hour. These abrupt changes have the effect of reducing the average efficiency of the whole system to a comparatively low figure. The engine and dynamo must be able to furnish the maximum energy demanded at any instant, whilst the mean power in many cases scarcely comes to one-third of the maximum. Measurements made by Dr. Louis Bell on several American electric tramways have shown that the efficiency of an entire system, taking the B.H.P. of the car motors, divided by the I.H.P. of the engine at the generating station, amounts in some cases to only 25 per cent., and that in no case does it reach over 40 per cent. in every day practice on a tram line. With electric railways having fixed stopping places at long intervals, with the time-tables so arranged that only on rare occasions several trains start simultaneously, a higher efficiency may be aimed at.

Electric light engineers will look with amazement, and perhaps envy, upon the variations in the voltage marked on Figs. 2, 3, and 4; but these are exceptionally great fluctuations, and there are many electric tramways where the volts do not vary more than 15 per cent. A sudden call for large currents always lowers the potential, and this is partly due to the feeders being proportioned to the average output, and partly to the momentary slowing down of the engine. When the governor begins to act, the excess load has very often already disappeared, and then there is a tendency to racing for the next moment, and a simultaneous rise of E.M.F. above the normal. At the City and South London Electric Railway, which is only 3¼ miles in length, the deflections on the voltmeter vary between 370 and 500, notwithstanding compound-wound generators, and a regular schedule time of running the trains. Several years ago I suggested a remedy for equalising, to some extent, the load upon the generating plant of an electric tramway with overhead conductors; but my sugges-

Digitized by Google

tion has not been adopted. I advised the use of secondary batteries to act as regulators—not batteries of large capacity, but such as would give a very high discharge rate. Plain lead plates of very large surface, formed on the Planté or any similar process, would certainly add to the smooth working of any railway or tramway where great fluctuations of load are unavoidable, and compound winding insufficient. An accumulator of this description could be made very cheaply, and, by allowing sufficient material, it can be of any durability desired. The diagrams show that the large excess of current is only required for a few seconds at a time; therefore a storage battery of large surface would furnish this in a far more rational way than the best designed dynamo worked by the most delicately governed steam engine. It would save engine power. and reduce the chances of breakdowns due to sudden shocks to the generating plant.

Again reverting to our diagrams, which, to the practised eye, reveal a number of interesting points, we find that, on starting a single car, from 20 to 50 E.H.P are absorbed, and this occurs just when the motor is giving a comparatively small mechanical power at its minimum efficiency; this energy is absorbed in producing the initial statical pull, which must be created by many ampere turns. Now, in order to get many ampere turns without excessive currents, I designed, some eight years ago, a switch which throws the motors in series when starting, and in parallel (when two or more motors are used) when a sufficient counter E.M.F. is created by virtue of a certain speed. I also subdivided the field-magnet coils, in order to obtain several graduations and regulate the fields to the requirements of the load and speed. Up to that time electric engineers used idle resistances for varying the speed and power. Mr. Sprague and others have adopted a similar method of regulation. The Thomson-Houston Company use resistance coils up to a certain point, after which portions of the divided field coils are thrown out of circuit. By a judicious arrangement of field windings to suit the exigencies of a given road, a very fair all-round motor efficiency can be obtained.

The battery car, from which diagram Fig. 1 was obtained, required for its propulsion 1·086 electrical H.P.H. per mile run, with an average load of 7 tons over a line having no gradient above 4 per cent. The figures obtained by Mr. O. Crosby on three American lines with overhead conductors accord with the above very closely. Thus, on the Richmond line the readings were 1·18 H.P.H. per car mile, at Cleveland 0·9, and at Scranton 0·94 H.P.H. These cars were very much lighter than the one driven by accumulators, but there is a gradient of 9 per cent. at Richmond, and one of 7 per cent. at Scranton, while the Cleveland line is tolerably level; the speeds at Cleveland averaged 9 miles per hour, and at the other two lines six miles per hour. The coal consumption measured at the generating stations came out as follows:—For the Cleveland line, 8lb. per car mile; and at Scranton, 5·6lb.; that of Richmond could not be ascertained, as the same boilers were used for both the tram line and the electric lighting plant.

On the Frankfort-Offenbach Tramway, and on the Mödling line, near Vienna, both built by Messrs. Siemens and Halske, the coal consumption varies between 7 and 8lb. per car mile. Unfortunately, I have not been able to ascertain the evaporative quality of the coals used in these places. Mr. J. S. Badger, in a highly interesting recent communication, relates that the very best station performance he met with in the United States was 1 E.H.P. for 5lb. of slack coal evaporating 7½lb. of water. Writing on the consumption of fuel in general on a number of American tram lines, he found that it varied between 4·3lb. to 12·2lb. per car mile, according to the quality of fuel and the nature of the road and load. Many of the American tramways have recently adopted large cars up to 25ft. in length inside, whereas the usual standard type of car is only 16ft., carrying a proportionately smaller number of passengers, although I have frequently seen 70 passengers occupying a 16ft. car intended to seat 22 people. Overcrowding is not allowed on English tramways.

I have collected a very large amount of material with regard to the all-important question of operating expense, and I am greatly indebted for information given by Mr. Alexander Siemens, Dr. E. Hopkinson, Mr. Holroyd Smith, the Allgemeine Elektricitäts-Gesellschaft, Mr. J. S. Badger, and Mr. Robert W. Blackwell. Full tabulated statements are appended: to read the same would occupy more time than is at our disposal; moreover, it would add to the monotony of an already very dry paper. With your permission, I will only make such observations regarding each table as may render some assistance to the study of them. Due regard should be taken, in each of the lines, to local conditions. In Germany, for instance, the wages, which form the principal item in the operating costs, are about one-half those paid in the United States. Wages and salaries in England take an intermediate position. Again, the cost of fuel varies in almost every city in the world.

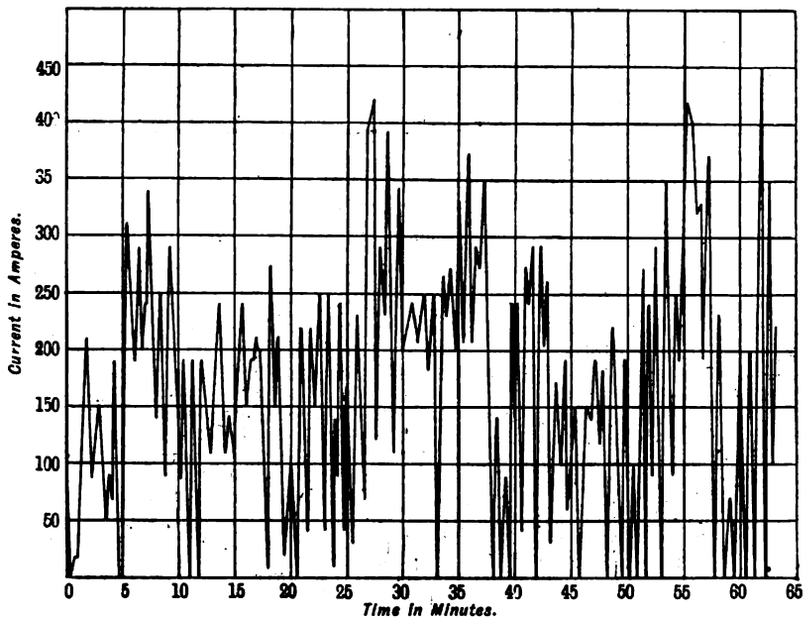

Fig. 5.—Roundhay Electric Tramway, Leeds. Ampere Readings at Generating Station, with five cars on the road. Mean E.M.F., 280 volts.

One of the oldest electric tramways in the world is that of Frankfort and Offenbach, in Germany. It was built by Messrs. Siemens and Halske, and opened to the public in April, 1884. Table I. shows the detailed working expenses for the year 1890, giving the sum of 4·608 pence per car mile, including all charges. The first financial year—1884-85—gave a much higher figure, namely, 8·256 pence per car mile; and it is interesting to note that the working expenses were reduced year after year: this was largely due to improved appliances and the consequent reduction in the maintenance items, as well as in wages. The expenses of the other tramways in the city of Frankfort (which are worked

with horses) for the year 1890 amounted to 9·022 pence per car mile, or nearly double that of the electric line. The slotted-tube overhead-conductor system is used here, and the entire rolling stock consists of only 14 cars—10 of which are fitted with electric motors, serving as tow cars—holding 24 passengers each. About 1,050,000 passengers are carried per annum; this is considered a very low figure, and is partly due to the competition of a local railway. In consequence of this small traffic, the ratio between expenditure and revenue is as high as 70 per cent., notwithstanding the moderate traction costs.

A more recent and equally interesting example of electric tramway enterprise in Germany is that of the city of Halle. The cars on this line were originally drawn by horses, but a year ago the municipal authorities gave permission to the Allgemeine Elektricitäts-Gesellschaft to erect overhead conductors on the plan adopted by Mr. Sprague in America. I am indebted to Mr. Emil Rathenau for a detailed statement of working expenses ranging over six months—from July 1st until the end of December, 1891. Table II. gives the averages per month and per car mile. The general expenses include taxes, municipal charges, and water-rates. The water is obtained from the town supply, the sinking of a well having been found impracticable. The rolling stock consists of 25 cars; the average number actually running was 20·55. They carry drivers, but no conductors, and this fact renders the wages account remarkably low, the entire working expenses coming to only 2·624 pence per car mile, or 54 5 per cent. of the gross revenue. It must be observed, however, that no allowance has been made for depreciation, which, if included, would add nearly another penny per car mile to the expenses account. Incidentally it may here be mentioned that the Imperial German Government stopped the running of the electric cars immediately after the opening ceremony because they interfered with the proper working of the telegraphs and telephones. The case came before the law courts, when the judges decided in favour of the tramway company, stating at the same time that the streets of a city were intended for general traffic, that their course could not be altered, but that the postal authorities could easily arrange the telegraph and telephone wires so that they should not be influenced by the electric lines, which use the rails and earth for the return circuit. The alterations were made, and the tramway has had a good time ever since.

The most remarkable of European electric tramways is that of Budapest, which was constructed by Messrs. Siemens and Halske, of Berlin. A few months ago I visited the Hungarian capital, and I was delighted with the perfect working of the electric cars. Underground conductors are used in this case, and the conduit is immediately underneath one of the tram rails, so that there is no additional slot in the roadway. About 50 electric cars are now in operation over 20 miles of track. The system is exceedingly popular, and it carries a larger number of passengers per mile than the horse tramways. This is probably due to the greater speed, the electric cars being allowed to run 11 miles per hour in some of the streets. I have not been able to obtain detailed working expenses, but I have been informed that the same never exceeded 50 per cent. of the revenue since the opening of the line two years ago. The ratio of working expenses and revenue on the horse-car lines at Budapest is 72 per cent.

Another among the numerous Continental electric tramways is that running between Florence and Fiesole, a distance of 4·5 miles, which was the first continuous steep-grade electric line in Europe. The Sprague system is used in this case. Table IV. is prepared from data contained in a recent Paper by Mr. C. P. Sheibner, of the Institution of Civil Engineers. The author of this interesting Paper gives, under the heading "Motive Power," the sum of the expenses arising through wages at the generating station, wages of car drivers, fuel, water, repairs, &c. These I have divided in my table in order to facilitate references with data obtained from other lines. It would be an excellent thing if all the electric tramways would keep a uniform record of all the details of working expenses, in the manner done by the existing horse tramways under the Board of Trade rules.

Coming now to electric traction enterprises in the United Kingdom, we find, in Table III., referring to the Blackpool Tramway, that the gross expenses amounted last year to 9·91 pence per car mile, or 57·8 per cent. of the gross receipts. This is a most satisfactory result, considering that the winter traffic of this seaside resort is only just sufficient to cover operating costs, and all the profits have to be earned during the holiday seasons. This is the only line in England, and the oldest line in the world, worked with underground conductors in a slotted conduit. The rent charged by the Blackpool Corporation for the use of the line forms a considerable item—1·773 pence per car mile—in the sum of the working expenses. Directors' fees and secretarial charges also seem to be liberally arranged, making 1·187 pence per mile.

On the Bessbrook-Newry Tramway, where water-power is used for driving the generators, the haulage costs during six months ended December 31, 1890, amounted to 3·97 pence per train mile. This includes water rent, rental of buildings; wages of driver, guard, and dynamo attendant; maintenance and repairs to dynamos and conductor; oil, tallow, and waste. During the period stated the train mileage was 10,400; the number of passengers, 50,800; and goods carried, 8,600 tons.

Table II.—The Halle Electric Tramways.

Working Expenses for Six Months ending December, 1891.

Average number of cars running	20·55
Total car miles for six months	266,796
Average number of car miles per month	44,466
" " " day	1,449·3
Daily average mileage for each day per car	70·6
Total gross receipts for six months	£5,354. 8s.
Average gross receipts per month	£892. 8s.

LEGAL INTELLIGENCE.

Lane Fox v. Kensington and Knightsbridge Electric Lighting Company (Limited).

WEDNESDAY, MARCH 30TH, 1892.

JUDGMENT.

Mr. JUSTICE SMITH: This is an action brought by Mr. St. George Lane Fox, an electrician of high repute, to test the validity of a patent taken out by him on October 9, 1878. The plaintiff alleges that he then hit upon the idea that by utilising secondary batteries as invented by Planté, and coupling them up to the mains which conveyed the E.M.F. in his system of distribution of electricity, such force could be kept constant in the mains, and then an even steady light would be had in incandescent lamps which otherwise would not be. The Attorney-General designated this invention as being one to keep a constant potential at the lamps with a variable load. It has been proved the system of distribution of electric current for incandescent lighting in conjunction with the use of secondary batteries by reservoirs was a novel and valuable suggestion, which has aided the perfecting of that science which has culminated in the incandescent lighting of the present day; and it certainly appears to me that if the plaintiff did invent and carry to a practical result what is now claimed for him, he is an inventor of very great merit. Some ten years prior to the year 1878 Gaston Planté had invented and brought into use what is known as a "secondary battery," that is, a reservoir in which the electric current emanating from a generator could be stored. Daniell, my brother Grove, and Smee had also invented cells to act as accumulators of electrical energy; and these were in common use in telegraphy and other electrical work. The use of switches was also well known. They were means by which an electric current could be turned on or off, whether into or out of an accumulator, or in any other circumstances in which it was desired to turn on or off the electric current. Prof. Forbes told me the switches were as commonly used in electricity as water taps in the distribution of water. This secondary battery of Planté consists of a number of cells joined together, each cell holding sulphuric acid, in which are immersed plates of lead rendered porous and oxidised by a process fully described by him. These secondary batteries had, before 1878, been used for the storage of electric energy, and utilised, among other things, for the purpose of ringing bells or kindling lights, the energy then wanted being let out of the secondary battery by the pressure of a button, as is well known to many. Prior to 1878, attempts had been made at lighting by electricity, the means adopted being to place arc lamps into what is called series, that is, into line, and to pass the electric current through each lamp, and thence to what is known as earth. This system, though suitable to the lighting of lamps in streets, and such like, was not adapted to the lighting of the interior of houses and other buildings, as is now done by incandescent lighting; and, to use the words of Sir Frederick Bramwell, a Director of the defendant Company, "the great question of the day was the distribution of electric light." In this state of circumstances the plaintiff took out his patent of October 9, 1878. In it, among other things, he sought to bring about a distribution of the electric current, or, in other words, to divide the main current into a number of small currents, branching off from the main current, and again branching off from them, so that by placing his lamps into what is called parallel, that is, at the side of the main current, instead of in a line with it, each lamp might be fed by a small current, which, when it had performed its mission at the lamps, and exhausted its energy, or, in technical language, had reached "zero potential," should pass on therefrom to earth. By this means of distribution of the electric current, and the other means stated in the specification, the plaintiff designed to light by incandescent lighting towns and other inhabited districts. The name the Attorney-General gave to the proposed system was "the multiple parallel incandescent bridge." The plaintiff, as before stated, for the purpose of carrying out his proposal, determined to couple up the secondary batteries of Planté to his system of distribution. The complete specification as it now stands, page 5, lines 42 to 44, states that "the purpose for so doing was to distribute and regulate the electric current for obtaining light by electricity." The plaintiff's case is that by coupling secondary batteries to the mains, the electric energy therein would flow from the mains into the batteries when the energy in the mains was above equilibrium, and also inflow from the batteries into the mains when the energy therein was below equilibrium, and that thus a constant potential would be kept in the mains, and the light in the lamps steady. The defendants, in the first place, assert that the specification shows that Planté batteries were resorted to by the plaintiffs, not for the purpose, as he now states, of regulating the electric current, but for the purpose of storing up what excess motive force might emanate from the generator when the load upon the main was light, or, in other words, when the lamps were off; and of using such stored up force when the load upon the mains became heavy—that is, when the lamps were on or when the generator was not at work. They say that the present claim of the plaintiff as to using secondary batteries for regulating the electric current is not to be found in the complete specification as it originally stood, and then it is only rendered possible by an adroit amendment made therein in the year 1883, when the second disclaimer took place. It becomes necessary to see what the complete specification did contain when filed on April 9, 1879. The Attorney-General, in opening the case, and again at the end of his reply, told me that if Mr. Lane Fox had now, in the year 1892, to sit down and re-write a provisional and complete specification of his invention of 1878, with all his subsequent knowledge, he would write it again in the same words and the same form. This statement in reply somewhat stretched my credulity, seeing that he and Sir Horace Davey had occupied me for fifteen days in trying this case, a very considerable portion of which had been taken up in discussing what the two documents meant. By the complete specification Mr. Lane Fox claimed for improvements in electric lighting by, amongst others, the six following means:—First, by means of the distribution of electric energy by mains of branches and sub-branches; second, by means of this distribution in conjunction with incandescent lamps; third, by means of an apparatus for measuring electricity; fourth, by means of the employment of secondary batteries as reservoirs in combination with his system of distribution; fifth, by means of the use of a regulator and other mechanism wherewith to regulate the E.M.F. in the mains; sixth, by means of mechanism wherewith to convey electric energy. On the 26th January, 1882, the plaintiff disclaimed his claim to his appliances wherewith to measure and to convey electric energy; and on July 30, 1883, he further disclaimed his claim to his distribution of the electric current, whether alone or in conjunction with the incandescent lamp, and also his claim to the regulation and other mechanism which I shall hereafter for the sake of brevity call the electrometer. It will be seen that all that was left of his patent, as the specification now stood, was his claim for distributing and regulating the electric current for obtaining light by electricity by means of the employment of secondary batteries as reservoirs of electricity in combination with a mode or system of distribution of electric energy. In the specification, after describing a lamp and the way of distributing the electric energy and the means for measuring it, the plaintiff makes this statement: "The E.M.F. of the electric conducting mains should be kept as nearly as possible constant at, say, 100 volts of British Association units of E.M.F." The Attorney-General in opening this case stated that this invention of 100 volts showed the foresight of Mr. Lane Fox, for it was the pressure now universally adopted. This, upon the evidence, appears not to be so, nor does there seem to be any special virtue at all in having a pressure of 100 volts. Dr. Hopkinson told me that at Paddington they are working a pressure of 130 volts; in the Law Courts a pressure of 85 volts; and in his own house he uses a pressure of 50 volts; but be this as it may, it has nothing to do with what I have to decide, as I stated during the progress of the case. Mr. Lane Fox then proceeds to deal with secondary batteries as follows, line 51, page 4, to line 6, page 5:—"A number of secondary batteries, such as Planté's (lead and sulphuric acid), such batteries being joined together in series between the main and the earth will serve as a kind of reservoir for the electricity. The cells should have a very large conducting surface, and there should be several batteries connected up at the various points of the mains, so that by increasing the E.M.F. during the hours when not much electricity is being used they will become charged, and the electric force will be stored up in them, so that a sufficient supply will be available when the E.M.F. falls owing to the draught from the mains when the force is most used and needed. The number of cells in each of these batteries will depend on the E.M.F. of the mains. Fig. 5* is a diagram representing a secondary battery joined up between the main and the earth for the purpose above described. E indicates earth, and L lamps." It is true that in the paragraph about secondary batteries Mr. Lane Fox does not mention anything about their being employed to keep the E.M.F. in the mains constant; but later on, at lines 14 to 16, page 5, he is explicit on the matter. He says: "In order to keep the E.M.F. in the electric mains constant, it is desirable to have, in the first place, several generating machines; also a number of reservoir batteries as before explained." He then goes on to disclose his electrometer, as follows:—"Next it is necessary to have some regulators such as that about to be described. In my regulator, I make use of what is known as the quadrant electrometer." He then describes the mechanism of the instrument, and finishes: "The E.M.F. can be regulated either in this manner or by otherwise effecting the action of the electric generators through the instrumentality of the currents set up by the pegs above described, so as to increase or diminish the action of the generator." It was known to electricians at that time that by reason of the resistance of the mains the farther the electric currents travelled up them from the dynamo, the less was the potential in that current, or, in other words, that by reason of the resistance of the mains the farther the lamps upon circuit were situated from the dynamos the less illuminating power they received. This, upon a long circuit, was matter of moment. Anxious as I am to read the specification in favour of the patentee, I cannot do so without seeing that Mr. Lane Fox, when he drafted it in April, 1879, had in his mind as regards the matter now in hand, two separate and distinct ideas. The one was that, by coupling up secondary batteries to his system of distribution of electric current, he might be able to neutralise the pressure of the mains, and thus render constant the E.M.F. therein (this would be in aid of the dynamo, as Prof. Perry stated). The other was to regulate such E.M.F. in the mains (and this, as it seems to me, was for the benefit of the lamp). These ideas are separate and distinct. Prof. Forbes stated, if it be evidence (which I think it is not), that his reading of the specification was that Mr. Lane Fox meant a constancy of pressure all over, and at all times; and Mr. Lane Fox, in cross-examination upon his lecture delivered at the Royal Institution in 1832, stated to the same effect. In my judgment the defendants are not correct when they state that Mr. Lane Fox, by this specification, only claimed the use of secondary batteries as reservoirs, for by these batteries he also claimed to keep the E.M.F. in the mains constant. I am against the defendants upon this point. The defendants, however, say that if the specification is to be read as I read it, the patent is bad, because the complete specification, as it now stands, is not in conformity with the provisional. This point appears to me to be a formidable one for the plaintiff. It is unnecessary to go over the earlier cases cited by counsel on either side, for they are dealt with in the late case in the Court of Appeal of *Nuttall* v. *Hargreave* ("First Chancery Division, 1892," page 23). The law is clear. It is this. A patentee must describe the nature of his invention in his provisional specification; he need not go into details, but he must describe, as I have said, the nature of his invention. In his complete specification, when going into detail, he must describe the

* See *The Electrician*, Feb. 26, 1892, p. 438.

Digitized by Google

same invention—if not, the patent is bad. Now, what has Mr. Lane Fox done here? In his provisional specification he states, "The E.M.F. for the electric conducting mains should be kept as nearly as possible constant, at say, 100 volts, or British Association units of E.M F. A number of Planté's (lead and sulphuric acid) cells joined together in series between the main and the earth will serve as a kind of reservoir for the electricity. In order to keep the E.M.F. in the electric mains constant it is desirable to have, in the first place, several generating machines." It must be noted that he does not here state that secondary batteries are available for this constancy, as in his complete specification he does, but proposes that the generators should keep the E.M.F. constant, and not even in conjunction with the secondary batteries. He then goes on to state that it is necessary to have the electrometer for the purpose of regulating the E.M.F This provisional specification, reading it most favourably for the plaintiff, can only be read to claim for the invention of using secondary baateries, the keeping of the E.M.F. constant. I have no doubt that in the complete specification, as originally filed in April, 1879, the words "regulating the electric current," at page 3, line 16, and at page 5, line 44, were solely applied to the electrometer. What has been done is this: Upon disclaiming the electrometer on July 30, 1883, four years after the complete specification, it was sought to apply the words "regulating the electric current," which had been theretofore applicable solely to the electrometer to secondary batteries, so as to claim for them not only the power of keeping the force constant in the mains, but of regulating it therein. The question is, does the plaintiff now claim for the same invention in his complete specification as it stands as he did in his provisional specification? I say he does not. In the provisional specification he claimed as his invention the use of secondary batteries in aid of the dynamo to keep the E.M.F. in the mains constant; whereas he now by his amendment of his complete specification claims as his invention the use of secondary batteries, not only to keep the E.M.F. constant in the mains in aid of the dynamo, but also to regulate the E.M.F. in the mains for the benefit of the lamps. The case is this: In the provisional specification he claimed by his use of secondary batteries, invention X in the Provisional Specification, he further claimed by his use of the electric meter, invention Y. In the complete specification he now claims by his use of the secondary batteries, inventions X + Y. How can it be said that he now claims in the complete specification the same invention as he did in the provisional, unless X and Y are the same invention, which, in my judgment, they are not, and what is more the evidence leads me to conclude that secondary batteries, when coupled up to a main, will under certain conditions bring about some of the regulating force originally claimed for the electrometer, but automatically will not bring about the constancy originally claimed for them. The eminent electricians called by the plaintiff in conjunction with those called by the defendants, have satisfied me that in some circumstances, especially when fully charged secondary batteries coupled to the plaintiff's system of distribution, have an inherent power of regulating the E.M.F. in the mains, but the amount and value of such power was matter of keen dispute. The evidence shows that the batteries, automatically worked, will not keep the E.M.F. in the mains constant. As to the power of regulation, Professor Perry, called by the plaintiff, stated that the compensating effect was a very important one, and that the advantage of the patent was to prevent flickering. The plaintiff declared this invention was a departure from many of the things written before 1878; and as regards that part of his invention for distributing electric current, together with coupling of secondary batteries to mains, I think may be so. Professor Silvanus Thompson stated that with batteries so placed the regulating effect is a necessary consequence. Professor Barrett stated that secondary batteries, he knew, would operate to bring about a constant pressure; and Professor Forbes said that they had the regulating effect spoken of by the witnesses, and he added, "I have always considered secondary batteries most essential for steadiness of light," and went so far as to say that he had never seen a steady light without secondary batteries. He then alluded to the lights of the Court in which I was sitting, and for which no secondary batteries are used, and told me that the lights were varying from 15 to 20 volts In my judgment, if this were so, for all practical purposes the light was an even and steady one, and as good as could be desired. The witnesses called for the defendants did not deny that secondary batteries had some regulating effect. Sir Frederick Bramwell said, "I think they may be acting as regulators in part. I think the batteries would help to maintain the constant pressure at the mains. I think the secondary batteries would tend largely to correct the rise and fall of voltage when lamps were turned on and off, the batteries would maintain or tend to maintain a constant E.M.F. at the lamps." He also stated that they could not be used automatically. Dr. Hopkinson upon this point stated:—"Secondary batteries will always diminish the flicker, if there were a flicker; they would have exactly the same effect with a steam-engine as with a gas-engine. If the batteries were taken away there would be absolutely no difference upon the pressure in the mains. There are scores of stations without batteries." Mr. Crompton stated that secondary batteries with switches remaining constant did not tend at all to diminish flicker. Mr. Miller, the resident engineer at Kensington Court station—that is, the defendants' station—stated that secondary batteries do not automatically regulate the potential, although he said in cross-examination if there be a change of pressure in the mains the secondary battery minimises the effect. Mr. Swinburne declared you could not use secondary batteries for storage so as to be of use against flickering. Mr. Kennedy, the civil engineer, who had made tests wholly unconnected with this action, produced them to explain the extent of regulating a secondary battery was capable of, and he stated that a secondary battery will help in regulating small variations, and he adds, "For very small variations such as continually occur in a circuit with many lamps, the secondary battery will help to steady the lights, they do not keep the pressure constant." Mr. Drake, who had been working practically at batteries since 1884, and has had hundreds of batteries under his charge, and who was, to my mind, a peculiarly intelligent witness, stated, "There is a prevention of flicker by use of secondary batteries if fully charged, even though the motive force be a steam engine and dynamo, that is, if the actions are very quick. If a few lamps are shut off in a small system so that the shutting off of a few lamps affects the light, the secondary batteries would help to regulate, but only for a few moments," and Mr. King, who had had great practical experience in manufacturing secondary batteries since 1883, and had made upwards of 38,000 experiments in charging and discharging them stated in cross examination, "I will swear there would be more variation (that is in the voltage in the mains) with secondary batteries than without them. I say the secondary batteries, the current running constant, tend to cause a variation rather than diminish it." It was proved that many installations were worked without the application of secondary batteries at all, the Law Courts being amongst the number; and, as before stated, Dr. Hopkinson deposed to scores of stations existing without secondary batteries. It is true that secondary batteries are extensively used, though obviously by no means universally. Mr. Drake told me that he was connected with about 250 installations of incandescent lighting, of which about one-third had no secondary batteries, and the other two-thirds had. He also stated, and I have no reason to doubt him, that the object of using secondary batteries was to serve as reservoirs to enable the engine to be stopped, and yet to have the incandescent lighting continued from the motive force stored up in the batteries. In cross-examination he said that he had some batteries on with the dynamos going, but that he charged them by day and worked them off by night. Sir Frederick Bramwell, Mr. Crompton, and others, gave strong evidence that the principal use of secondary batteries was as reservoirs, and this appears to me to be the case. Scientific evidence was given to show what was the real rise and fall of voltage in the batteries and mains upon the application or withdrawal of the E.M.F. therefrom. This evidence was illustrated by diagrams which it is impossible to reproduce here even if it were desired to do so. In my judgment the plaintiff as to the controlling effect of secondary batteries has placed his case too high, and that the real truth is that if there be a short quick flicker at a lamp, a secondary battery coupled up with the main will at times help to diminish it; but the secondary batteries, as designed to be used by the plaintiff, that is, without mechanical and manual devices, will not bring about that constancy of pressure which the plaintiff claimed for them in his original specification. The result of the evidence upon this head I may, I think, accurately sum up in the words of an article in the *Engineer* newspaper of December 26, 1890, which the Attorney-General used largely in cross-examination of the defendants' witnesses. Mr. Crompton, Mr. Miller, and Mr. Kennedy said that the words were fairly accurate. They are as follows:—"One of the advantages found by having more than one pair of batteries attached to the system at points totally wide apart is, that the effect of the regulating movement of switching in an extra cell which would show a difference of two volts on the lamp is partly neutralised by the distant battery." Mr. Lane Fox, in his declaration made in March, 1883, stated that the effect of the change of about one volt upon a lamp was practically nothing; and if Prof. Forbes was correct in stating that there was a change of from 15 to 20 volts in my Court, it is obvious that a two-volt change is of little importance. The Board of Trade sanctions a change of 4 volts up and 4 volts down. In my opinion, the point taken by the defendants is fatal to the plaintiff's case, and that the complete specification as it now stands does not claim the same invention as the provisional.

I might stop here, but, as others may not agree with me, I shall give judgment also upon some of the other points raised. The next question which I take is that the plaintiff has claimed as an essential part of his system of distribution a return by the soil of the earth and which the defendants say is impracticable; the part of the specification which deals with this is as follows: "The way in which I distribute the electric energy so as to work a number of these lamps from a single source of electricity is represented in the diagrams Figs. 3 and 5, and is as follows: from one pole or electrode of the electric generator or generators situate at "A" (Fig. 3) proceed one or more large conductors from which branch out at various points where lights are desired smaller conductors which again may have conductors branching off from them, and so on. The other pole or electrode of each electric generator is connected with the earth, so that the conductor and its branches and sub-branches will be perpetually in a state of electric tension, tending to develop currents in every direction to the earth. One pole of the electric lamp is connected with the earth "E," and this may be conveniently effected by means of gas or water pipes when such exist, so that whenever the circuit is complete between the lamp and any of these branches a current of electricity will pass through the thin strip or wire, rendering it incandescent and so produce light." It was clearly proved that as regards the effective distribution of the electric current either of the three well known return conductors if practicable would be equally efficient, the three being the soil of the earth, an insulated or an uninsulated metallic conductor. It was also clearly proved that the plaintiff's system of distribution of the electric current ended at the positive pole of each lamp. The defendants assert that the plaintiff claims as part of his system of distribution a return by the soil of the earth; and secondly, that if he has not claimed the soil of the earth as the sole return conductor, still, he has claimed it as being one amongst others to be used, and that as the soil of the earth cannot be used for the purpose claimed, it makes the specification bad; and they cite *Simpson* v. *Holliday* ("English and Irish Appeal Cases," (page 315), in support of that proposition. An enormous amount of evidence was given as to what technical meaning was or was not to be attached to the words "earth," or "the earth." I am not going to review it, and the following are the conclusions I have arrived at. It was established that the word "earth" in a specification without a controlling context would have indicated to an electrician in 1878 that any of the then well-known return conductors, that is the soil of the

Digitized by Google

earth, an insulated or an uninsulated metallic conductor, might be used. It was also proved that the like might be said of the words "the earth." It is true that at times the word "earth" is used in this specification; but when it is used in that part of the specification which specifically deals with the mode of distribution of the electric current, it is always "the earth." "The other pole of the electric generator is connected with the earth." "The conductor, &c., will be perpetually in a state of electric tension, tending to develop currents in every direction to the earth." "One pole of the electric lamp is connected with the earth, and this may be conveniently effected by means of gas or water pipes." It is common ground that the way a return current is connected with the soil of the earth is by what are called earth-plates, that is, a metallic plate or plates by which a good connection with the soil is attained for the return current. The way I read these last lines is, "One pole of the electric lamp is connected with the earth, which connection (I put in those words) may be conveniently effected by means of gas and water pipes;" or, in other words, the gas and water pipes are to act as earth plates. If the return connection has to be by a return other than the soil of the earth, as now suggested by the plaintiff, the stipulation for a connection with the earth by way of earth-plates would be meaningless, for no such provision would be required. I have no doubt that the words "the earth," read as they must be in connection with the context, mean the soil of the earth, and that alone. It is further argued by the defendants that the plaintiff must be taken to claim a return by the soil of the earth as essential to his invention because of the well-known expense attending the other returns in the case of lighting by electricity. Sir Frederick Bramwell has stated that out of a capital of £135,000 or £140,000, his Company has had to pay, for its return conductors alone, no less than £35,000 or £40,000. Other witnesses spoke to the great cost of metallic returns for lighting by electricity. I may point out that Prof. Perry, when pressed in cross-examination as to the meaning of the words "the earth," stated, "I have no doubt he (the plaintiff) intended to use the earth as a return conductor, that is, the earth as it exists." Prof. Perry was correct when he gave that answer. This being my reading of the term "the earth" in this specification, I have to inquire whether a return by the soil of the earth in a system of incandescent electric lighting such as designed by the plaintiff, could be worked. The evidence as to this is in reality all one way. One or two of the plaintiff's witnesses did at first make an effort to support the theory that it could be used, though not one single instance of the soil of the earth being used in the case of incandescent lighting as a return conductor was or could be produced. Dr. Hopkinson told me that the soil of the earth could only be worked on a very small scale, and could not be practically worked upon a system such as is represented by Mr. Lane Fox. Sir Frederick Bramwell also stated that a return by soil was not practicable for incandescent electric lighting, by reason of the large number of amperes that have to be dealt with, and that he had never known a return by soil successfully used in electric lighting. It is true that in telegraphy the soil is an effective return, but in such case the return current may be measured by a very small fraction of an ampere; whereas, to supply even the 328 lamps shown upon Mr. Lane Fox's Figure 3, and which represents only part of a larger system, it would require at least 125 amperes. In my opinion, it is not practicable in Mr. Lane Fox's system to obtain or use earth plates of sufficient size so as to make an efficient connection with the earth, on account of the magnitude of the current which would have to be provided for; and, even if it were, such a voltage would have to be used to get through the earth plate as to be out of all reason. In my judgment, a return by the soil of the earth has been proved to be unpracticable for the plaintiff's system. But although this is so, should I hold that the plaintiff claims a return conductor by the soil of the earth as being an essential part of his system of distribution? for if not, the point will not avail the defendant. The Attorney-General has satisfied me that I should not, and for this reason. It is the fact, as stated by Mr. Swinburne, that in 1878 any electrician would know, that if he did not want to use the earth—that is, the soil—he could use any other return conductor. It was proved by Sir Frederick Bramwell that "when you got your current into the return wire all object of subdivision has ceased. What you want to distribute is the current with potential in it—that is, with the effective energy in it." "It does not matter one farthing," says Sir Frederick, "if the return is soil or an insulated or uninsulated conductor." "The unsuitability of a soil return is because of the magnitude of the currents you are dealing with." This coming from a witness of the defendants' is conclusive. So it appears to me to show that a return by the soil of the earth is not an essential part of the plaintiff's system of distribution of electric currents. I notice that in the specification Mr. Lane Fox has claimed for distributing the electric current by "earth," which would not necessarily mean in the context the soil; so also as regards the distribution in connection with his lamps. I hold that Mr. Lane Fox, as part of his system of distribution which terminated at the positive pole of the lamp, did not claim a return by the soil of earth as an essential part of his system of distribution; and I decide this point in his favour. The case of the *Electric Telegraph Company* v. *Brett*, ("10th Common Bench," page 838), is somewhat similar to the present case, and, as far as it is similar, it is an authority for what I hold. I now come to the question upon which evidence was adduced, partly of a highly technical and partly of a practical kind, the question being whether, if Mr. Lane Fox's specification were followed out (apart from the question of the earth, about which I have nothing more to say) it could be made to work; and, if so, whether sufficient information was therein given to enable the intelligent electrical workman of 1878 to make it work. I was surprised to hear the Attorney-General, in reply, suggest that the specification did not claim for the automatic action of the electric current between the mains and the batteries. For fifteen days I had laboured under the impression that the plaintiff's case was that he did, and upon referring to my notes there can be no possible doubt upon the subject. The Attorney-General, when opening the case, stated, "It is not saying too much to say, my lord, as skilled electricians will tell your lordship, that, remarkable as it may be, every system of modern successful electric lighting which proceeds from generators, dynamos, and which is absolutely maintained at a constant pressure—what I call automatically maintained, without other devices for keeping the current constant, is an exemplification of Mr. Lane Fox's discovery and system." Again, "The number of cells in each of these batteries will depend on the E.M.F. of the mains." "That means," says the Attorney-General, "that these secondary batteries are in the position described, 100 lamps are on, they do not require more than one-tenth of the current which is being generated, the rest of the current goes into the secondary batteries, night comes on and 2,000 lamps are on instead of 100; and, accordingly, then, all the current is required, both coming from the engine and coming from the secondary batteries, and the engine and the secondary batteries give off at a constant pressure of 100 volts the current required for the lamps." The case proceeded upon this assumption of automatic action, and hours were occupied in giving evidence and discussing as to what plate area in the cells was required to bring about this automatic action. It is true that switches were referred to, but they were mentioned as being possible improvements upon Mr. Lane Fox's patent, and having been in common use in 1878, it was said that an intelligent workman would use them if he found he needed them to aid the automatic action. Prof. Perry, the first witness in the case, when asked to describe the plaintiff's invention, stated, "When the engine which drives the dynamos goes a little too fast, so that the pressure in the main tends to be too great for the lamps, the battery stores the surplus supply of energy; when the dynamo goes too slowly, giving out too little energy, the battery unstores, helping the dynamo." He then made a sketch showing how it acted, and added, "the secondary battery is an automatic regulator, in fact." The plaintiff in chief also described his system in such terms as only to describe an automatic action, and during his cross-examination he said to me, "I say in the specification it is stated that as an increase or decrease of energy is wanted in the mains, it is given out or taken in automatically." This is the plaintiff's own definition of what his own specification would bring about, and Prof. Barrett said, "In my opinion, switches seem only a cheap way of doing what Mr. Lane Fox proposes to do without them, and that it is better without switches." The Attorney-General's suggestion in reply is not well founded. The defendants' case was, that secondary batteries, when coupled up to mains with lamps on circuit, could not be automatically charged so as to be of utility, because to charge a secondary battery in such a position, such a voltage or pressure would have to be used as would destroy the lamps on circuit, unless resort were had to a system of manual and mechanical appliances, in the form of extra cells and switches, to keep the voltage off the lamps when the batteries were being charged. It appears to me that in 1878 Mr. Lane Fox had not rightly ascertained the voltage required to efficiently charge a secondary battery when coupled up to a main, and that he was then under the impression that a very slight excess of voltage was necessary either to charge or discharge it. It is manifest that he laboured under this impression, at any rate, till as late as March 14, 1883, when he made a statutory declaration for use upon the application for his second disclaimer. In this he deposed as follows:—"I say that when the E.M.F. is increased during the hours when not much electricity is being used, as described on page 4, lines 56 and 57, the few lamps turned on during the day would not be far too bright and would not be liable to break for the reason that, as would be obvious to any electrician, the increase of E.M.F. for fully charging the batteries need be very slight, less than a volt, the effect of which upon the lamps would be practically nothing." Prof. Perry also stated that with a force "of 101 volts you can charge the cells to 100 volts, that the batteries will charge and discharge with less than 1½ per cent. difference, and the plaintiff also stated "that the voltage should be kept as near 100 volts as possible." The Attorney-General, upon the seventh day of the trial, still insisted that 101 volts would charge a battery with 100 volts. Prof. Forbes, called for the plaintiff, by no means adopted this view of the case, but stated, that he had some tests which would show that you could charge a secondary battery with 5 volts excess, but that it took 20 hours to do so, and he did not state to what point upon the curve he arrived at with that voltage. It has been demonstrated to me by a large body of evidence that this suggestion of being able to charge a secondary battery at anything like an excess of one volt is an error, and that it cannot be done. I will single out the evidence of Mr. King and Mr. Drake, the most practical of all the witnesses called before me, as regards the charging and discharging of secondary batteries when coupled up to mains. Mr. King stated: "With an excess outside the battery of one volt you would get into the battery a very small amount of anything; indeed, something quite inappreciable. I say that, in practice, you have to get to 105 volts before you get any current into your battery any moment, and at this, the amount would be exceedingly small." Mr. Drake satisfied me that an excess of one volt was useless, and my impression is that Mr. King is about right when he stated that 105 volts are required before anything of utility is done as regards commencing to charge a secondary battery. It has been made quite clear to me that it requires a considerable excess voltage to charge a secondary battery, the reason being that it is necessary to overcome not only the internal resistance of the battery, but also the E.M.F. generated by the chemicals therein, which resists the entry of the electric current. The excess of only one volt, in my judgment, is practically useless. It is this initial mistake of the plaintiff which, as it appears to me, has caused him to describe in his specification the automatic action between the batteries and the main; and I may here state, for reasons hereinafter appearing, that in my judgment automatic action with lamps on circuit is impracticable. The evidence upon the question of what excess voltage is required to charge a secondary battery on the main is very voluminous, but I think I may summarise it as follows. I take what has

Digitized by Google

been called the "plateau" theory, and use for the purpose of explaining it, Prof. Ayrton's curves. Many other curves have been put in evidence, but for the purpose I have in hand Prof. Ayrton's will suffice. The first question is, to what point upon this curve must a secondary battery be charged so as to discharge with utility, by which I mean to discharge in such a way as to keep or tend to keep the E.M.F. in the mains constant when such force falls, owing to the draught upon the mains. The Attorney-General says up to point "B" on this curve* is the proper point. Mr. Finlay answers him, and says, if only up to "B" your plateau theory of the automatic discharge breaks down, for you then get next to no plateau at all upon the discharge; and in this Mr. Finlay appears to be correct, and this without taking into account the sudden drop to about 15 per cent. of what admittedly takes place when passing from the charging to the discharging of a battery. If the charging and discharging curves are examined, it will be seen that with the battery only charged to "B" on the charging curve, the whole of the plateau upon the discharging curve, namely, from "A" to "B" is lost, and a sharp decline at once begins, which obviously will not bring about the theory of constant pressure in the mains when a load is placed upon them. The evidence given leads me to the conclusion that to charge a secondary battery so that it should discharge as desired by Mr. Lane Fox, the battery must be charged at last up to "D." The uncontradicted evidence shows that to charge up to "D" requires a voltage of 120 volts, to charge up to "C" requires a voltage of 113 volts, and to charge up to "B" (the Attorney-General's limit) requires a voltage of 110 volts. I will, however, here assume for this part of the case that the Attorney-General is right, and that point "B" is the point to charge to, though I do not agree with him. There is no question that it takes a voltage of 110 volts to get there. Prof. Perry told me that 103 volts would not be a damage to the lamps, that 105 volts would destroy the lamp within a reasonable time, that if you had to go up to 110 volts it probably would break the lamps, it would smash every lamp very soon, that 125 volts would destroy a lamp under an hour, and that 150 volts would kill the lamp in a few seconds. The plaintiff put the limit at 105 to 106 volts. He said that for some time you might go up to 110 volts without danger to the lamps—it would not tend to diminish its life very much; but to 105 or 106 volts you could press without detriment to the lamps, and he added, but I think wrongly, and he disagreed with the Attorney-General's theory of charging to "B," that 105 or 106 volts would be amply sufficient to charge a secondary battery. Prof. Silvanus Thompson gave the following list to show the effect of high voltage upon a lamp:—If a pressure of 95 volts is used, the life of a 100-volt lamp is 3,595 hours; if a pressure of 96 volts is used, the life of a 100-volt lamp is 2,751 hours; if a pressure of 97 volts is used, the life of a 100-volt lamp is 2,135 hours; if a pressure of 98 volts is used, the life of a 100-volt lamp is 1,645 hours; if a pressure of 99 volts is used, the life of a 100-volt lamp is 1,275 hours; if a pressure of 100 volts is used, the life of a 100-volt lamp is 1,000 hours; if a pressure of 101 volts is used, the life of a 100-volt lamp is 735 hours; if a pressure of 102 volts is used, the life of a 100-volt lamp is 601 hours; if a pressure of 103 volts is used, the life of a 100-volt lamp is 477 hours; if a pressure of 104 volts is used, the life of a 100-volt lamp is 375 hours; if a pressure of 105 volts is used, the life of a 100-volt lamp is 284 hours. I arrive at the conclusion that 105 or 106 volts is, at any rate, the maximum pressure which can or ought, in practice, to be placed upon a 100-volt lamp. It will be seen that with 105 or 106 volts, point "B" upon Prof. Ayrton's curve is not arrived at, it requires 110 volts to get there; and this, according to the plaintiff's witness, Prof. Perry, would probably break the lamp —would smash every lamp very soon. It will be noticed that with a voltage of 105, Prof. Silvanus Thompson states that a lamp has only an existence of 248 hours. What a voltage of 110 would bring the lamp down to can well be surmised. Then how can it be successfully contended that without some contrivance to keep the pressure off the lamp when the batteries are being charged even to "B," the plaintiff's specification can be made to work? It cannot be, and from these facts alone I come to the conclusion that the defendants are correct in their contention. In these circumstances it is not necessary to go further and deal with the weighty evidence given, that, in practice, to keep the batteries "in health," as it is called, that is, capable of performing their proper functions, they must repeatedly be charged up to above "D," and, consequently, to a voltage of 125. This evidence, in my opinion, is correct. If this be so, it is, *à fortiori*, that secondary batteries cannot be efficiently charged excepting at a voltage which, according to the plaintiff's own witness, would destroy the lamps under an hour. It was then said on behalf of the plaintiffs, supposing this to be so, still, if the plaintiff's specification be followed, and the plate area in the cells be increased, so as to have "a very large conducting surface," the voltage could be reduced to such a dimension that the batteries with lamps on circuit could still be charged automatically. I cannot do better than cite from Prof. Barrett's evidence to show what difficulties the plaintiff was in when this proposition was put forward. In cross-examination by Sir Horace Davey, the following took place:—"(*Q.*) You have used the words 'sufficiently large,' 'very large,' will you condescend to particulars? (*A.*) I can only give you my own experience. I should say 'very large' means with reference to what was known and in common use at that day. I should say nothing but trials would show, probably the first trial would be successful. It is a matter of individual judgment. Say, five times as large. It depends upon the size of the mains and the current, the larger the current the larger should be the conducting surface." Sir Horace Davey then passed on to other matters, but the next morning proceeded as follows:—"(*Q.*) I was asking yesterday what very large cells meant. (*A.*) Very large conducting surface has a definite meaning, in addition to that which I gave. It obviously means that the cells should be relatively large with the installation so that by increasing the E.M.F. a sufficient supply wil be available when it falls owing to the draught in the main—that is, large enough to supply sufficient when the draught in the main is most needed." I own that neither this evidence of Prof. Barrett nor any other given on behalf of the plaintiff satisfies me that by increasing the plate area in the cells to any practicable degree the excess voltage above pointed out would be got rid of, and what is most remarkable is that no evidence was adduced to show that it had ever been attempted, that the suggested result had been produced in practice. There is another fact also, which, to my mind, is of the highest import, viz., that for the 13 years this patent has been running, with the exception of what Prof. Barrett described as a small installation in his laboratory used for lecturing and teaching purposes, not one single installation has been in actual work upon the automatic principle with success. The case of Lady Conyers' ball, in 1882, put forward as an instance of the plaintiff having been successful with his automatic system, is not, in my opinion, an instance at all, as I will presently show. In the plaintiff's installation in Paris in 1881, there was no secondary battery used. At the Crystal Palace installation in 1882 switches were used. About the installation at the Brush Company in 1882, in which at first secondary batteries were used without switches, the plaintiff stated as follows:—"There were no switches in the Brush Company at first, but they may have been put in. I think at first the light was found to be irregular. The batteries soon deteriorated and went wrong; it was then found desirable to put in switches." "It may have been that the Brush Company very soon afterwards put in switches to avoid the irregularity which existed. It may have been thought desirable that switches should be added." At the King of Roumania's Palace in 1883, the installation had a regulator on the steam valve, as also an arrangement for switches. At the installation at the Opera House in Vienna, in 1883, there was an elaborate design for switches, though it was said that these were used to produce scenic effects; and at the installation for the Drapers' Company there were also two switches. These were the instances produced by the plaintiff of the practical working of his invention, not a single one, as it appeared, worked automatically with success. At Lady Conyers' ball at Queen's Gate, in 1882, an installation of about 70 lights was put up under the superintendence of Mr. Lane Fox. It was erected for the single night, and was the first of its sort. It certainly was not a success, for the lamps all went out in the midst of the dancing; but I take it that this is to be accounted for by the fact, as stated by Mr. Lane Fox, that at one period of the evening a crowd got into the engine-room and caused a disconnection, which was afterwards put right. It is true that on this night secondary batteries were used without switches, but it is also true that these batteries were sent up to Queen's Gate from Mr. Sellon's fully charged, though, as Mr. Lane Fox says, some of the acid had fallen out on the way. Mr. Erskine told me that these secondary batteries were used because they had not a large enough engine, and that in the afternoon the lamps were not bright, and that, by bringing up the batteries and attaching those to the main, they got in the evening a good light by the extra power attained out of them, and that the voltage used was between 45 to 60 volts. Mr. Lane Fox states that the batteries, when coupled up to the mains, continued to be charged and discharged during the installation, but he made no investigation of this at the time, and I am by no means convinced that Mr. Lane Fox's belief as to the charging is accurate, In my judgment this installation cannot be taken as a practical test as to whether secondary batteries can be automatically charged with lamps on circuit as required by the specification. The small laboratory experiment by Mr. Barrett from 1886 downwards, is the sole installation which Mr. Lane Fox can find, during the 13 years his patent has been in existence, to bring before me as an instance of the practical working of his system. I cannot accept this as substantial proof of the practical working of the plaintiff's system, as I am invited to do by him. It is but a small laboratory installation, used solely for teaching purposes, to describe the system of incandescent lighting, to show the effect a battery will have upon the short quick oscillation of a gas engine, and used with one, two, or three lamps at a time, though there were 10 lamps in all upon the circuit. Prof. Perry told me, and I have no doubt truly, that in his laboratory he had found he could charge a secondary battery at an excess pressure of one volt, a fact which has been demonstrated beyond question cannot be performed in the actual practical working of mains with lamps on circuit. Prof. Barrett told me that his engine produced amperes considerably in excess of what was wanted at the lamps, that he runs with a current of 18 amperes, his lamps only requiring 10, and that his batteries were not used for helping the dynamos, for they were not wanted for that purpose. I cannot think that this one small laboratory case, under the circumstances, is sufficient to outweigh the other cogent evidence given upon this head. Prof. Silvanus Thompson, upon cross-examination, stated that he had not in his experience known of a system of secondary batteries put up without switches. I am alive to the point made by the Attorney-General that if plaintiff's invention could be made to work so as to be of practical utility, it was none the less a good invention because improvements therein were subsequently made, and I agree with his law as to this. The question is could the plaintiff's invention, as described in his specification be made to work in practice? In my judgment, for the reasons above, it could not, and that ground is also sufficient to defeat the plaintiff's patent. I now come to the last point upon which I purpose to deliver judgment in detail, and that is, supposing the specification could be made to work so as to carry out the plaintiff's invention, was sufficient information given therein to the intelligent electrical workman of 1878? I must here observe, as has been often done before, upon the difficulty the Court is in in being called upon to ascertain the state of knowledge existing at the date of the specification, and more particularly is this so in the present case, considering the length of time which the plaintiff, for some unexplained reason, has allowed to elapse before bringing the validity of his patent to the test. The law as regards the sufficiency of description in a specification is as follows:—The specification may call upon a workman to exercise all the

* See *The Electrician*, Mar. 4, 1892, p. 466.

Digitized by Google

actual existing knowledge common to the trade: but it must not call upon him to exercise his ingenuity or invention, see per Alderson, Baron, in *Morgan* v. *Seaward* (2 "Meeson and Welsby," page 544); nor cast upon the public the expense and labour of experiment and trial, per Abbott, Chief Justice, in *Rex* v. *Wheeler* (2 "Barnewall and Alderson," page 345); per Lord Abinger, in *Macnamara* v. *Hulse* ("Carrington and Marsden," page 471); per Pollock, Chief Baron, in *Stevens* v. *Keating* (2 Exchequer, page 772); and to use the words of Sir George Jessel, in *Plimpton* v. *Malcolmson* (3 Chancery Division, page 531), taken from those of Baron Alderson, it must not "take the form of a problem." It is said that the workmen of 1878 would have known two things: first, of what size the "very large conducting surface of the plates in the cells" should consist, so as to get rid of the excess voltage; and, secondly, that he would have known if he could not make the system work that he could apply extra cells and switches, so as to be able to cut the cells out from the circuit when the batteries were being charged. The evidence as to this is in conflict. The four Professors called by the plaintiff assert that there was plenty of information given in the specification, whilst the evidence for the defendants was to the contrary. As regards the state of knowledge in 1878, it must be remembered that this was the year of birth of electric incandescent lighting; and, indeed, in the next year it would appear that but little was known about it, for in 1879 a Parliamentary inquiry was held as to the practicability of electric incandescent lighting, at which some of the greatest electricians of the day gave evidence, amongst them Sir William Thomson, Sir William Siemens, and Dr. Hopkinson; and it would seem that they were by no means agreed as to its feasibility. I ask myself what would an intelligent electrical workman then know of what size and dimensions the conducting surface of the plates should be to charge a secondary battery when coupled up to a main so as not to damage the lamps on circuit? At that date he had never seen a secondary battery coupled up to the main for the purposes then for the first time suggested by Mr. Lane Fox: he knew nothing of what voltage would be required to charge such a battery in work, any more than Prof. Perry or Mr. Lane Fox did: he knew nothing of the nature of an incandescent lamp, and he knew nothing of what amount of voltage such a lamp would bear. In these circumstances how could he tell the size or dimension of plate area he should use in his secondary battery to do away with some unknown excess voltage? There is not a suggestion as to size given excepting that there should be "a very large conducting surface." In my judgment no electrical workman, nor do I believe any electrician of the highest eminence, could in 1878 have worked out Mr. Lane Fox's specification without both experiment and invention, and then he would have found that the system would not work automatically as described. Even in 1892 Prof. Barrett had but a hazy idea of what "the very large conducting surface" should consist. Upon this point I think the defendants are also in the right, and that there is no sufficient description of the invention in the specification. Now, as to the switches, the plaintiff is in this position. If his system of distribution can be made to work automatically without switches, no point arises upon them. If, however, as I hold, it cannot be made to work without them, then his system is not automatic, and upon this ground the switch point cannot avail him. I may, however, observe that although I have no doubt an intelligent electrical workman in the year 1878 would have known how to apply a switch to a secondary battery, that this by no means shows that he would have been able to apply the necessary number of extra cells and switches to secondary batteries in such a way as to effectively carry out Mr. Lane Fox's mode of distribution. It appears to me that the workman would, as regards these switches and extra cells, have been in a similar position of perplexity as the workman called upon to adjust cells with "a very large conducting surface." I need not recapitulate these difficulties, and the observations I have made thereon apply here. I hold also that in this respect also there is a deficient description. I have now held that this patent is bad upon the ground that the complete specification does not conform to the provisional, upon the ground that the invention as described cannot be made to work, and also upon the ground that if it could, no sufficient information is given as to how it has to be made to work, and I have stated my reasons fully (perhaps too fully) for so holding. It is not necessary to give any further judgment in this case; but had the plaintiff been able to surmount the above-mentioned difficulties, and had established that by his invention he could have brought about what the Attorney-General said he could, my judgment would have been that his invention was the subject matter of a patent, that it had not been anticipated, and that the defendants had infringed it. I give judgment for the defendants, with costs.

Savory and Moore v. London Electric Supply Corporation (Limited).

In the Court of Appeal, yesterday, the case of Savory and Moore *v.* London Electric Supply Corporation came before Lord Justice Lindley, Lord Justice Bowen, and Lord Justice Kay in the form of an appeal by the defendants from a judgment of Mr. Justice Kekewich (see *The Electrician*, December 25, 1891, p. 203). The plaintiffs are manufacturing chemists, carrying on business in New Bond-street, and they alleged that owing to the manner in which the defendants carried on their business, a fire occurred on their premises. They brought an action against the defendants, and Mr. Justice Kekewich granted an injunction restraining the defendants from so using certain portions of their buildings for converting electric currents in such a manner as to occasion a nuisance and a danger to the plaintiffs. The defendants now appealed against that judgment.

Mr. Moulton, Q.C., and Mr. Hamilton appeared for the defendants in support of the appeal; while Mr. Rigby, Q.C., and Mr. Warmington, Q.C., opposed it on behalf of the plaintiffs.

Mr. MOULTON was about to open the case for the defendants in support of the appeal when,

LORD JUSTICE LINDLEY suggested that the action should be settled. He wanted to know what Mr. Rigby required the defendants to do.

Mr. RIGBY said if the defendants would undertake to use their transformers where they said they were going to use them, the plaintiffs would be satisfied.

Mr. MOULTON said defendants would give an undertaking that no transformers should be put in the ground floor of their building until it was as fireproof as the basement was at present.

Mr. RIGBY said he should suggest precautions which ought to be taken to make the ground-floor safe.

LORD JUSTICE BOWEN asked if the plaintiffs would be satisfied if the defendants undertook to use no place but the basement of their buildings until the necessary precautions had been taken.

Mr. RIGBY replied in the affirmative. He would also like an undertaking that the defendants would not place combustibles where their transformers were.

Mr. MOULTON said the defendants would agree not to store combustibles in the room with the transformers.

It was eventually agreed that the injunction should be dissolved on the defendants paying the costs, and undertaking not to use any room of their building, except the basement, until a gentleman, appointed by the parties, was satisfied that proper precautions had been taken against fire, and not to store combustible material in a room in which there were transformers

CORRESPONDENCE.

ROTATING FIELD ELECTRICITY METERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As you have introduced my name in connection with an alternating current meter now being manufactured by the Ferranti Company, I think it right to state that the meter alluded to was invented by Messrs. Philpot and Alderton in conjunction with myself in 1888, and that a part interest in it was acquired by Mr. Ferranti in 1889. Since then it has been remodelled and clothed in Mr. Ferranti's patented double-sealed case.

As this meter formed one of the earliest examples of the rotary field motor which lately has attracted so much attention, and was certainly the first in Europe in which a rotating field was produced directly from an ordinary alternating current, I feel it is rather hard on my co-inventors to have it illustrated merely as a "Ferranti Electricity Meter."

I need hardly say that Fig. 3 on page 538 only represents in the very roughest way how the rotating field is produced, as no satisfactory motor or meter could be made with pole pieces constructed as shown in the figure, because probably the whole of the energy would be absorbed in heating the iron, instead of being gradually transmitted along the poles to the armature.

—Yours, &c., ARTHUR WRIGHT.

26, Park crescent, Brighton,
25th March, 1892.

ELECTRIC HAULAGE IN GERMAN MINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On page 480 of the current volume of *The Electrician* we find some particulars taken from the *Colliery Guardian* with regard to electric traction in the Neustassfurt, Zaukerode, and Hohenzollern mines. We beg to point out that all the locomotives in these three mines were supplied by this firm, and not partly, as stated by the *Allgemeine Elektricitäts Gesellschaft*. The figures given also are quite old, as they refer to about the year 1888. In the pamphlet we send herewith you will find the figures for 1891; from them you will observe the progress that electric haulage has made on these three roads.—

Yours, &c., SIEMENS AND HALSKE.

Charlottenburg, March 24, 1892.

[From the pamphlet issued by Messrs. Siemens and Halske we find that the average number of waggons hauled per day in the three mines to which we referred is at present as follows:—

Neustassfurt.	Zaukerode.	Hohenzollern.
1,200	700—800	2,000

These three lines were entirely equipped by Messrs. Siemens and Halske.—ED. *E.*]

[Owing to extreme pressure on our space, we are compelled to leave over several Letters to the Editor.]

Digitized by Google

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—The Chiswick Local Board invite tenders from electric lighting companies or other persons willing to take over the lease of the Chiswick Electric Lighting Order (1891) for the supply of electricity in the district of the Local Board, and for carrying out the duties and obligations of the Board under the Order, for a term not exceeding 21 years. Further particulars are given in our advertisement columns. Sealed tenders have to be delivered to the Chairman, at the meeting of the Board, on Wednesday, May 4th next, at 8 p.m., at the Vestry Hall. All further particulars can be obtained of Mr. Robert F. Finnis, Clerk to the Vestry, Chiswick, Middlesex.

SALE BY PRIVATE TREATY.—The machinery, plant, patterns, tools, finished and unfinished stock-in-trade, fixtures, and good-will of the National Telegraph Works Company (Limited), in liquidation, are offered for sale by private treaty, and the business is for sale as a going concern. Some further particulars are given in our advertisement columns, and full particulars can be had of Mr. James Rhodes (the receiver for the debenture holders), chartered accountant, 34, Waterloo-street; or of Messrs. Cottrell and Son, solicitors, 25, Waterloo-street, both of Birmingham.

FAILURE.—The following is the list of creditors under the failure of Mr. William D. Berry (trading as W. D. Berry and Sons), electrical engineer, Clara-street and Brook-street, Huddersfield :—

Heppenstal, G. H., Fartown	£17	0	0
Armitage, Joseph, Huddersfield	18	0	0
Liversedge, Law, Huddersfield	10	0	0
Consolidated Telephone Company, Ltd., London	39	0	0
Glover, Walter T., and Co., Salford	13	0	0
Lauder, R., and Co., West Hartlepool	62	0	0
Day, C. F., York	50	0	0
And some creditors under £10.			
Total	£342	13	9
Secured	£0	12	6
Net assets	£244	2	10

DISSOLUTION OF PARTNERSHIP.—The firm of Messrs. Dawson, Willmer, and Clift, draughtsmen and engravers, has been dissolved; and the business will in future be conducted by Mr. Leslie Everitt Clift, under the style of Leslie E. Clift and Co., at 1, Holborn-place, High Holborn, London, W.C.

BUSINESS NOTICE.—Messrs. Wynne and Barnard inform us that since the dissolution of the firm of Barnett, Wynne, and Barnard they have commenced business as electrical engineers at Grey-street, Newcastle-on-Tyne.

INCANDESCENT LAMP PATENTS.—The Edison and Swan Company issue the following caution :—"Users of the electric light are hereby specially cautioned against purchasing or using lamps now being illegally offered for sale by German makers with the assurance that they are exempt from this Company's patents. All other electric incandescent lamps than those made by the Edison and Swan Company, and marked with their name, are infringements of this Company's patents, and legal proceedings will be taken against every person found using them."

MANCHESTER ELECTRIC LIGHTING.—The Electric Lighting Committee of the Manchester Corporation have, we understand, now placed all the contracts for the work required. Messrs. Mather and Platt have received orders for two large shunt-wound-Edison Hopkinson dynamos with an output of 410 volts, 590 amperes, speed not exceeding 400 revolutions per minute, and a guaranteed efficiency of 91 per cent. These machines will be almost exactly similar to those supplied to the Central Generating Station of the City and South London Railway. The Electric Construction Corporation have also received orders for dynamos. The boilers will be supplied by Messrs. Galloway, and the machinery be driven by belts. The whole of the mains, bare copper and insulated conductors (and the laying of same), and conduits, will be supplied by the International Okonite Company. Although the system adopted by the Corporation is a low-tension one, high-class insulation has been determined upon, the specification calling for an insulation resistance of 2,000 megohms per mile. The work will be commenced directly after Easter, and the Corporation anticipate furnishing the light by about midsummer.

AN ELECTRIC SAW MILL.—An installation of wood-working machinery for Lord Rothschild has just been erected at Tring Park. The plant comprises band saw and circular saw machines, for converting logs, deals, &c., as also planing, moulding, mortising, and tenoning machines, the whole of which are driven by E.M.F. The machinery has been supplied by Messrs. A. Ransome and Co., of Chelsea, and erected under the superintendence of the resident engineer, Mr. C. Burman Callow. Although isolated machines have been driven by electricity, we believe this to be the first complete saw mill worked under these conditions.

WATER-POWER INSTALLATION.—Mr. A. A. C. Swinton has the arrangement of a water-power installation at Moy Hall, near Inverness, the residence of The Mackintosh of Mackintosh, which is being lighted with the electric light. The source of power is a water turbine, supplied by a 50ft. fall, situate at a distance of half a mile from the house. Bare copper overhead conductors, with accumulators, will be used.

THE CHICAGO WORLD'S FAIR.—We understand that the British Commissioners have decided to extend the time for receiving applications for space, and in this connection have decided to hold a meeting at Manchester. 42,000 square feet of space has up to the present been applied for, the average per exhibit being 30ft. in excess of that taken at the Paris Exhibition.—On Saturday last a credit of two million marks for Germany's participation in the World's Fair was granted by the Reichstag; and Herr von Boetticher stated that the space allotted to German exhibits at Chicago was larger than that assigned to Germany at any previous Exhibition, and that still more space would be required.

THE BRUSH ELECTRICAL ENGINEERING COMPANY, LIMITED.—This Company have contracted for the supply of electric light, plant and accessories for the forthcoming International Horticultural Exhibition to be held at Earl's Court. The actual lighting arrangements will be under the control of Mr. A. H. Wood, electrical engineer to the Earl's Court Exhibition Syndicate, Limited.

HYDRAULIC TOOLS AND MACHINERY.—Messrs. Woodhouse and Rawson United have sent us an illustrated catalogue of their Payne-Gallwey hydraulic machinery.

THE RATING OF MACHINERY.—The Rating of Machinery Bill is down for second reading in the House of Commons for Wednesday next, April 6th, and machinery users are earnestly requested to ask their representatives in Parliament to be in their places on that day to support the Bill. This is a subject which interests a large number of our readers, who will doubtless do all they can to assist the efforts which are being made to put the subject of the assessment of machinery on a sounder footing than at present.

THE ENGINEERING EXCHANGE.—A public meeting is to be held at the Cannon-street Hotel, on Wednesday, April 6th, at 2 p.m., to place this project in a complete and concrete form. The following outline of the features of the new Exchange will enable engineers and merchants to comprehend the manner in which it will serve their interests and convenience. The Exchange will form a central address and place of meeting for all parties interested in engineering business, and especially as a rendezvous for country members and foreigners visiting London on engineering matters. The rooms will be furnished with a view to meeting the requirements of members, who will find conveniences for correspondence, postage, periodicals, telephones for London and provinces, and boy messengers. Desks and lockers will be provided, as far as the premises will permit, for the private use of members paying a special fee in respect of same; and a patent and reference library will be established. A daily hour of meeting will be fixed by the Committee of the Exchange. The Exchange will be open between the hours of 10 a.m. and 7 p.m. daily, and later on special occasions, such as evening meetings of societies, &c. A complete set of rules and regulations, based upon those of other Exchanges, has been drafted by the hon. secretary, and will be submitted to the permanent committee, to be elected at the general meeting. The committee will be re-elected yearly, at a general meeting of members. The terms of membership will be as follows :— The first list of members, without entrance fee, £5. 5s. per annum; after the first list, £5. 5s., and an entrance fee of £5. 5s. per annum; authorised clerks of members, £3. 3s. per annum. Visitors introduced by members admitted for three weeks on payment of £1. 1s.

ELECTRO-HARMONIC SOCIETY.—A smoking concert will be held at the St. James's Hall Restaurant this (Friday) evening, at 8 o'clock.

COMPANIES' MEETINGS & REPORTS.

Notting Hill Electric Lighting Company (Limited).

The third ordinary general meeting of this Company was held yesterday at Winchester House, Old Broad-street; Prof. William Crookes, F.R.S. presiding.

The SECRETARY (Mr. W. H. Fox) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said: Gentlemen, it is unnecessary for me to say much about the present position of the Company, as this is so fully gone into in the report and accounts now before you. There are one or two points, however, to which I should like to draw your attention. In 1890 you subscribed about £70,000 to be devoted to lighting our district by means of electricity. To us was entrusted the very responsible task of spending your money in the most efficient manner for the furtherance of that object. We have now spent the money in the way it was intended to

Digitized by Google

be spent, in the purchasing of a site for the central station, in erecting on it substantial buildings and powerful machinery, in laying miles of culverts, copper mains, and cables, and in getting together a thoroughly efficient staff. We are now just beginning to reap the first-fruits of our labours. We may be compared to a farmer who, after buying a farm, and spending a large sum on agricultural machinery, seed, fertilisers, and labour, is now waiting confidently for the reward of his outlay in the shape of a heavy crop. We ourselves are in the transition state between the building up of a good business and reaping the benefit of our expenditure; and we must all exercise a little patience, for neither in agriculture nor in electric lighting will the crop follow immediately after the seed has been sown. The accounts are not quite so clear as I hope they will be in future, as they are for a broken period of seven months; and, owing to the large amount spent on capital account, many of the current expenses which under ordinary circumstances would have been charged to revenue account, are, in accordance with the Board of Trade regulations, charged to capital. Turning to Table No. III., capital account, you will see that by far the largest portion is for buildings, machinery, accumulators, and mains. Like the gas and water companies we must provide for the probable maximum demand during several years to come; for it would not be tolerated that the streets should be broken up at frequent intervals to keep pace with a rising demand. The proper apportionment of mains to streets was a subject of long and anxious deliberation on the part of your Directors and staff. It is not possible for any body of men to locate the position of greatest demand, to foresee all contingencies, and estimate the results of every move, especially when so much of the work is tentative, and there is no previous experience to serve as a guide. But our mistakes have been surprisingly few, and simply amount to this: we have put more copper strips and run more culverts in some of our streets and roads than we perhaps should have done had we been able to foresee the vagaries of the demand for current. When we first plotted out the mains and culverts, we naturally looked for most custom from the more highly-rented houses, and accordingly provided extra copper and culverts. To our surprise and disappointment, these roads have for the present brought in comparatively little, while streets in which we anticipated much less demand, have come forward in an unexpected manner, and have served to pull up the average. No particular harm is, however, done. We have only anticipated a demand which is bound to come before long. In Table No. IV., revenue, the total on each side is for seven months. Twelve sevenths of these totals come to—Expenditure, £3,733; income, £2,780; debit balance, £953. In this form the table is somewhat misleading for reasons above mentioned. I shall return further on to this subject. Table No. IX. also requires a few words of explanation. Look at the 8th column: "Quantity not accounted for, &c." This looks as if we had allowed nearly 11,000 units, worth about £340, to run to waste. I am happy to say such a reflection on our management is quite unwarranted. The "loss" of 10,996 units is accounted for as follows:—Lost in distribution: Energy expended in overcoming the resistance of the mains, being an average of 5 per cent. on the total accounts for 1,640 units; energy lost through leakage or through errors of meters, 612 units; unavoidable loss in using secondary batteries, difference between input and output, 3,958 units; used in testing meters and other apparatus, 1,025 units; energy discharged from the batteries through a water resistance during the months of May, June, July, and August, this waste was necessary in order to keep the batteries in good order. The quantity could have been sold had there been a demand, 3,731 units—Quantity not accounted for, &c., 10,966 units. This gives a total of energy lost in distribution of 18 per cent. on the total quantity accounted for, and about 11 per cent. of necessary waste. I do not think there is another company in London which can show more satisfactory figures than these. At the present time we are obliged to put up with a certain amount of loss in the use of secondary batteries; but this is far more than made up by the saving they effect. Had we no batteries, some of our most expensive machinery would have to be duplicated, and a double staff of assistants would be required, involving an expenditure of about £660 in extra wages. If we do not count the 3,731 units deliberately run to waste for the purpose of keeping the batteries in good order—a waste which can scarcely occur again—it is seen that our only real "loss" of current is a trifle of 612 units, which may be divided between errors of meters and leakage in mains. Some of the machinery would have to be duplicated, and a double staff would be required, involving an expenditure of about £660 in extra wages. Our real "loss" of current is a trifle of 612 units, which may be divided between errors of meters and leakage in mains. We opened our works at the end of May last, and with the exception of a few hours when the current was stopped owing to a burst water main flooding a culvert, the current has been on day and night without intermission. I am not aware of a single complaint as to the supply. We commenced with 22 houses and 2,411 lamps of 8 c.p., and we have at the present time 80 houses and 8,076 lamps. There are also 12 more houses, containing 976 lamps, coming on almost directly, so within about a year of our opening we shall have 92 houses and 7,052 lamps on our mains. (This does not include the houses and lamps in the proposed Phillimore district, where there are about 24 houses wired or intending to be wired.) Let me show you the significance of these figures by telling you what other companies, having, like ourselves, statutory powers in London, have done. I will first take the case of our good friends and neighbours, the Kensington and Knightsbridge Electric Lighting Company, as their system is the same as ours, their district a very similar one to our own, and their consulting engineer, Mr. Crompton, is the consulting engineer to ourselves. In 1887 they commenced with 9 houses and 360 lamps; in January, 1889, they had 61 houses and 4,425 lamps; in January, 1890, they had 141 houses and 11,359 lamps; in January, 1891, they had 291 houses and 25,355 lamps; while they commenced this year with 436 houses and 38,408 lamps. To appreciate the full significance of these figures, they must be presented in the form of a curve, such as I now put before you. The ordinates represent months and years, while the abscissæ show the number of 8-c.p. lamps on the mains at any date. The black curve gives the rate of increase of the Kensington and Knightsbridge Company from year to year. Notice how modestly they commenced with less than 500 lamps, not getting to 1,000 for more than fifteen months; and how gradual their rise was after then, until at the end of 1889 the demand increased, and the curve now looks like some high mountain peak. The red curve on the other diagram shows our own increase of lamps. Starting from the higher level of over 2,000 lamps, our curve is similar in character to the Kensington and Knightsbridge curve of 1888-89; and from all the indications I anticipate our rise will be equally marked by the time we have been in existence as long as they have. I have not been able to get quite as accurate information respecting the other companies; but I may tell you that the St. James's, the Metropolitan, the Westminster, and the House-to-House Companies also show an increase in their lamps more or less similar to the curve of the Kensington and Knightsbridge Company. On the basis of the facts before us let us see what is the present position of the Company. The accounts only give the position from May to Christmas, and they take in the summer months when we had but few customers, and some of these were away from London. In the first place, what would be our position in the impossible case of our curve of rise suddenly stopping? What if we get not a single more customer? How do we stand? Well, I think it will be satisfactory for you to know that we should be now paying our way, and even putting a few pounds to the good. From long experience the different companies have discovered that they can gauge pretty accurately the income from their lamps by multiplying the total number on their mains by a certain number of shillings, to be found out by experience. I have ascertained what this multiplier is in the case of some of the other companies, and here are the figures. The Kensington and Knightsbridge Company, in 1888, said that the revenue per lamp per annum was 13s. They now say it is a little less than 10s. The Metropolitan Company give the revenue at 12s., the Westminster consider it to be 15s., and the St. James's over 19s. The mean of all these is 13s. 10d., but; as I wish to be on the safe side, I will take 10s. per lamp per annum as our probable revenue. If, therefore, we stand still from the present time, and assume our lamps to remain at the figure above given, 7,052, our revenue should come out as follows:—7,052 lamps, at 10s. each per annum, £3,526; rent of meters and switches, £100; profit on stores, lamps, &c., £50; rents of houses, &c., £154—total £3,830. To get our expenditure I asked our engineers to give me in a tabular form the highest figures which they thought it was at all likely would be attained in any of the departments for an output based on 7,500 lamps. The table is as follows. In some cases the figures are certainly beyond the mark, but I retain them, as I wish to avoid any appearance of exaggeration:—Wages and salaries at the central station, £939; coals for 7,500 lamps, £470; petty stores (oil, waste, &c.), £75; water, £36; maintenance, £500; office expenses, Directors, secretariat, £1,400; sundries unforeseen, £100—total, £3,520. Therefore, remaining stationary at the present point, we have:—Probable income, £3,830; probable expenditure, £3,520; credit balance, £310. But it is certain that we shall not remain stationary. Even now inquiries and half promises are coming every week. The Kensington and Knightsbridge Company rose in twelve months from about 6,000 to 15,000, or two and a half times; and I see no reason why we should not rise in the same proportion. The lamp patent will expire next year, and several competing lamps will be in the market. It is expected that the price will then fall from about 4s. each to about 1s. 6d. each. This cannot fail to give a great impetus to electric lighting. Comparing the two curves before you, and interpolating our own curve in advance for twelve months, we see that the probability, almost amounting to certainty, is that by the time we have been at work for two years we shall have at all events twice the number of lamps on our mains, or say, 15,000. On the above basis of calculation our income and expenditure will then be as follows:—Income: 15,000 lamps at 10s. each per annum, £7,500; rent of meters and switches, £200; profit on stores, lamps, &c., £100; rents of houses, &c., £154; total, £7,954. Expenses: Wages and salaries at central station, £939; coals for 15,000 lamps, £938; petty stores (oil, waste, &c.), £150; water, £72; maintenance, £700; office expenses, Directors, secretariat, £1,400; interest on capital expenditure of £2,000 for crossings and extensions of mains, at six per cent., £120; sundries, unforeseen, £100; total, £4,419. Therefore, on the supposition that our lamp increase follows the normal curve, in twelve months' time we shall be working at something like the following rate: probable income, £7,954; probable expenditure, £4,419; total, £3,535. I will not dwell on the fact that to pay a 5 per cent. dividend, a sum of not more than £3,200 is required, but I cannot avoid asking you to look once more at the two curves before you, and to judge for yourselves whether it is likely we shall stop at 15,000 lamps, and a mere 5 per cent. dividend. I beg to move:—

"That the report of the Directors and the accounts to December 31st, 1891, submitted to this meeting be and the same are hereby approved and adopted."

Mr. A. E. FRANKLIN, in seconding the resolution, said that the Directors held in their own name £14,320 out of the £70,000 paid up capital, which could leave no room for doubt that they regarded their interests as identical with those of the shareholders, and was a guarantee for the good management of the business. The present quotation of the shares in the market was no criterion of the value of the Company's property.

The motion was carried *nem. con.*

The CHAIRMAN: I beg to propose—

"That Messrs. F. Radford and A. E. Franklin, the retiring Directors, be re-elected Directors of the Company."

Mr. J. T. JARVIS seconded the motion, which was carried unanimously.

Digitized by Google

Mr. REEVES proposed—

"*That Messrs. Deloitte, Dever, Griffiths and Co., be re-elected auditors of the Company.*"

Mr. BENSON, seconded the motion, which was carried unanimously.

An extraordinary general meeting was afterwards held, at which the CHAIRMAN proposed the following resolutions:—

"*That the remaining 2,998 shares still unissued of the 10,000 shares in the Company, or such less number as the Directors may determine, be issued, and as between such shares and the other Ordinary Shares issued, or to be issued, such shares shall be Preference Shares, and issued under the title of Ordinary Preference Shares.*

"*That the Ordinary Preference Shares be entitled to receive out of the sums for the time being applicable for the payment of dividend or bonus on Ordinary Shares, a dividend at the rate of six per cent. per annum before any payment by way of dividend or bonus be made to the rest of the Ordinary Shares already issued or to be issued, and that the right of the Ordinary Preference Shares to preferential dividend as aforesaid, be cumulative, so that the deficiency (if any) of one year to pay such preferential dividend, be made up out of the sums applicable for dividend or bonus on Ordinary Shares in any succeeding year or years, before any payment, as aforesaid, be made to the rest of the Ordinary Shares.*

"*That after and in addition to the payment of such preferential dividend of six per cent. per annum, including arrears (if any) of dividend from previous years, the Ordinary Preference Shares shall also be entitled, but not until the holders of the rest of the Ordinary Shares shall have been paid a dividend for the year at the rate of six per cent. per annum, to participate with the rest of the Ordinary Shares pari passu, and without distinction in dividend or bonus available for division over and above such six per cent. per annum payable to the holders of the rest of the Ordinary Shares.*

"*That in case of any return of capital in respect of Ordinary Shares, or of winding-up, the holding of such Ordinary Preference Shares shall not entitle the holders thereof to any preference in the return of capital or in the distribution of assets, but in respect thereto the Ordinary Preference Shares shall rank as Ordinary Shares.*

"*That the time, conditions, and extent of the said issue of Ordinary Preference Shares be left to the Board, to regulate, determine and carry out.*

"*That the preferential rights in respect of the holding of the Ordinary Preference Shares are only to be as between such shares and the rest of the Ordinary Shares, and shall not under any circumstances affect, prejudice, postpone or abridge the rights under the Articles of Association of the holders of Founders' Shares.*"

Mr. S. WATERS seconded the resolutions, which were agreed to.

On the motion of a SHAREHOLDER, Seconded by Mr. REEVES, a vote of thanks was accorded to the Chairman and the other Directors.

The CHAIRMAN, in expressing his acknowledgment, assured the meeting that there was not a Company in London that had a more zealous or hard-working Board.

The proceedings then terminated.

The above resolutions will be submitted for confirmation, as Special Resolutions, to an Extraordinary General Meeting to be held shortly.

The following is an abstract of the report of the Directors of this Company to the 31st December last above referred to:—

The expenditure on capital account amounts to £67,845. 13s., in which sum are included amounts due but unpaid on December 31, 1891, for machinery, construction of works, mains, &c. The 7,002 shares subscribed have been paid up in full, and 6,318 of the ordinary shares are officially quoted on the Stock Exchange.

The Company commenced to supply current to consumers at the end of May, 1891; the revenue account, therefore, for a period of only seven months, shows a debit balance of £617. 5s. 7d. This includes a sum of £250 for Directors' fees for the quarter ending December 31, 1891, which have not been drawn, and which the Directors do not intend drawing until the Company has made further progress.

The amount of electricity sold during the quarter ending December 31st was about four times as much as that of the previous quarter. The Company has constructed and laid 5½ miles of culvert and pipes, into which has been placed 66 tons of copper strips and cable, the whole costing £26,794. 6s. 8d. These mains run past 445 houses, which can be supplied practically without further outlay, and opposite to 331 additional houses which can be supplied by simply crossing the roads.

[The district lighted by the Company's mains is shown in the map recently issued as a supplement to *The Electrician*.]

Of the houses only 77 were supplied by December 31st, the number of lights installed being equivalent to 6,056 eight-c.p. lamps. The Company has orders in hand for a further 560 eight-c.p. lamps, and is now in negotiation for many more in connection with the existing mains. It may, therefore, be fairly reckoned that the increase during the current year will be very considerable.

The Company is now in possession of a first-class central station, thoroughly well equipped, and capable of supplying current to meet largely increased requirements at a comparatively small additional outlay. It possesses freehold land in Victoria-gardens, upon a portion of which the existing works are built, the remainder being let at a remunerative rental; and seven leasehold cottages adjoining, most of which are let to the Company's workmen. The whole of this property, including expenses in connection with acquirement, has cost £7,390. The buildings which have been erected cost £10,797 0s. 10d. They are of the most solid and permanent description, and it is not expected they will require any additions or improvements for many years. Should, however, in the future, larger space be required for the works, the adjoining freehold land belonging to the Company can be utilised for extensions.

The accumulators and copper connections at the generating station have cost £4,892. 17s. 1d., and no further expenditure on this account is expected at present. The meters, switches, and cut-outs fixed on installations cost £572. 7s. 6d.; these are rented to consumers, and are a source of independent revenue. The fixed machinery has cost the Company £7,965 5s. 8d., and the works as they now stand are capable of generating sufficient electricity to supply installations aggregating 21,000 lamps; reckoning on the usual basis, proved by experience, that only one-third of these would be simultaneously used at any one time.

The Directors have contracted for an extension of the mains southward, where a considerable number of householders have promised to take current, 14 houses having been already wired in anticipation. The cost of this extension will be paid for either by the issue of preference shares at par to the contractors, or by instalments which have been arranged for on terms convenient to the Company. A site for a battery station has also been secured in the Addison-road, or S.W. district.

The Directors propose to issue the remainder of the ordinary share capital in the form of Six per Cent. Ordinary Preference shares, powers to issue which will be sought in accordance with the terms of the notice enclosed therewith. The object of this issue is to enable the Company to extend its mains to further remunerative portions of its area, and it is the intention of the Directors to give the present shareholders the first opportunity of taking their proportion of these shares.

The London Electric Supply Corporation (Limited).

The fifth ordinary general meeting of the shareholders of the London Electric Supply Corporation, Limited, was held at the Cannon-street Hotel last Friday; Mr. James Staats Forbes presided.

The MANAGER and SECRETARY (Mr. Charles B. Waller) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, I presume that as the report has been printed and circulated, you will take it as read. A good deal of my life has been passed in trying to make the best of a bad business, and it seems to me that that is what I have got to do to-day. They say you cannot inspire belief in others unless you believe in yourself; and I have been trying to find whether in these figures and this report there is really any ground for despair, or whether there is any ground for hope; and I have solved it in the figures themselves by resorting to that wonderful qualifying thing, the "if." And really I do not know that I could put it to you more graphically or more truly to represent the actual position of things than by saying this—that if something had not happened which has happened, the state of things would have been that, instead of meeting to deplore a loss, we should have met to pronounce a profit. Now, if you kindly turn to the revenue account, which is the essence of the whole business, I will present to you that proposition in the figures. It is account No. 4, page 9, and there you will see that the total outlay upon the year has been £22,517. 19s. 7d., and that the total receipts have been £15,560 17s. 11d., and that there is a loss by balance of £6,957. 1s. 8d., showing exactly the money which has been spent in excess of what has been received. And then arises my "if;" and why is this thing? Now, in 1890, the previous year, the receipts were £28,684, while in 1891, as you see, they were only £15,560; and, as I have said, if something had not happened which has happened—that is to say, that if in the interval the calamities of the Company had not led to a great number of consumers who were customers in 1890 leaving us altogether, and so reducing the year's income by £13,124—our position, of course, would have been very different. If you go to the expenses of 1890, you will find that they amounted to £28,704, while in 1891 they amounted to £22,517, and that accounts for the greater part of the adverse balance; and therefore it comes to this, that if we had remained in the position that we ended 1890 in we should have had a profit instead of a loss, and the difference would have been exactly in that shape which is so agreeable when it is in the right direction, and so disagreeable when it is in the wrong direction. The £6,100 odd of profit is turned into that amount of loss, making, of course, £12,000 to the bad. That is the long and short of our experience; and the reason we have got into this position in the current year you are already possessed of, because last March, when we met to deal with the accounts of 1890, the calamity had already occurred—the fire at the Grosvenor station—which suspended our business between November, 1890, and February, 1891; and that, of course, took away the greater part of the customers that were lighted up by us at the date of the fire. Perhaps I had better illustrate the operation of this by figures. On the 15th of November, 1890, the date of the Grosvenor fire, we had 312 customers, with 38,272 lights. Of course, when the fire came the whole thing collapsed, and for many weeks there was no supply at all. It was not until February of last year that we were able to begin to light up again, and the change of circumstances was such that, instead of having 38,272 lights, we had only 9,000, and that 9,000 has been growing from day to day almost—certainly from month to month—ever since. I will read this table, as it is rather interesting. On the 15th of Febuary we, having had that long interregnum, had devoted ourselves and the ability of all the engineers and advisers we have to starting the thing on something like a permanent basis, for you know that the Grosvenor was a mere transition machinery—a sort of pioneer machinery—and we had to remove the whole of the plant from the Grosvenor station to Deptford, so that Deptford might supersede the Grosvenor, and become the sole source of supply. A good deal of time was occupied, a great deal of money was spent, and we started in February with the belief that, at all events, we had got a machine which would run; and although we had ascertained, naturally,

Digitized by Google

that a great many of our customers had departed, we thought we had a business which would very speedily return as a consequence of our better installation at Deptford. We had, however, to begin with 9,000 lights, and that number has gradually increased, by slow steps, until it has now reached, on the 22nd of March, 36,463; so that we have had, as it were, a whole year in order to overtake the numbers who had lights from us when that disastrous fire took place in November of the preceding year. But, unfortunately, the anticipations of the engineers, upon which we founded our expectations, were not realised to the full, because although it became an ascertained fact that current could be generated at Deptford, and could be transmitted to London, and there redistributed to the consumers, we had not attained in the first period of that experiment that perfection of the parts upon which efficiency depends, and we suffered the same kind of disaster which very often befalls experiments. The theory is right enough, but in practice it is not quite so efficient as it might be; and that is our experience. After we had started this thing, and after people began to come back to us, we had casualties—breakdowns of the mains, breakdowns of transformers, breakdowns of dynamos, interruptions of the light, and so forth; and a very serious calamity of that sort occurred in the month of November, when, from that curious coincidence of causes which it is impossible to trace—of course, there must be a cause, but it is a cause beyond the comprehension of any electrician or engineer I have been able to meet with—the whole thing came to a collapse. Dynamos, mains, and everything went wrong, and for four days or more we were without light. There was in a lesser degree what took place when the Grosvenor fire occurred. We had worked up our customers from 9,000 lights in February to 36,000 in November. Then came our disaster, and down went the numbers again, and, of course, not only did the numbers go down, but people who had not contracted to take current from this Company were alarmed. Some clubs went off, as did other people. That will all count for the state of the balance sheet at the end of the year—a disjointed year, a year which only commenced in the middle of February, and which had in itself the elements of such drawbacks arising from these accidents and break-downs as seriously to retard the progress of the business, and, in fact, to diminish the numbers of customers who from time to time had been induced to come in. That is where we are, and that is why the income, instead of being what it would have been if we had started the year with the same number of people when the Grosvenor station broke down, has shrunk by £13,000. But although the income has shrunk the expenses have remained the same, because this expensive machinery has to be carried on; and whether you light 9,000 or 36,000 lamps, the expenditure, save in the items of coal and water and some slight stores, remain the same; the fixed charges are really not in the least affected. This is what accounts for this exceedingly unpleasant result upon the year. But there is one item which one cannot carry to the profit and loss account in the balance sheet, and that is the value of the experience gained during the year. We were very anxious that the proprietors of this undertaking should know as much about it as we do ourselves, and therefore in the last two preceding reports we were very careful to have in black and white from the engineer of the Company (Mr. Ferranti) his views in unmistakable language as to the position of this experiment; and the worst that can be said about Mr. Ferranti's views is that they were somewhat too sanguine; but it looks very much like this—that the experience of these break-downs has led us to believe that they were only too sanguine, and not in principle wrong, because it may be interesting to you to know that these various accidents, interruptions to the dynamos, interruptions to the mains, interruptions to the transformers, beginning in very considerable ratio in the early months, diminished in the latter months of the year to zero. It comes to this, that the theory being right, the application or adjustment of the parts being involved, and at the same time a very delicate thing, has to be made, not in a drawing or on paper, or as an abstract proposition, but has to be felt out in practice. The result was shown the other day—I should say the other days—when London was blessed with a fog of not only great density but prolonged endurance—four or five days and nights. During that time our machinery at Deptford ran in the most perfect manner. There was no hitch or halt all these hours. It was maintained at full pressure all that time, and ran to perfection. Therefore, to sum up, we open the year with an amount of experience as to the possibility of this thing which represents, in fact, a very large value. Of course, I need hardly say that the Board room of this Company during these many months has not been altogether a bed of roses. I daresay it will be as satisfactory to you to hear as it is for me to tell you that the difficulties we have passed through and the experience we have had in these months has left our minds—I speak in the presence of most competent gentlemen—in a much happier state than at the beginning of the year and during many periods in the year. We think it is possible to develop this system of high tension to an extent and at a cost which, notwithstanding the very bad start, and notwithstanding the possible loss which will result from entering upon an experiment of this novelty, will eventually land the Company in a successful position. I do not know whether you would like me to go into much more detail. The report of the engineer is given at some length, and that is probably more worthy of your careful study than any remarks I have to make or anything in the body of the report; but for the sake of being in order I will go through the paragraphs of the report. I have told you already what the result of the year's working has been, and why it has been affected. We are now doing the whole of our work by the subterranean mains, concentric or otherwise. We lament—and I think this is the experience of some other companies—that the extension of electric lighting has not progressed with the rapidity which was anticipated. In our case I am not surprised at this, for the reason that we have had these interruptions and breakdowns. You need not be very distressed, however, if you make a loss in the first year or two. I remember a company connected with electrical supplies, with which I am also connected, which for several years showed year by year a heavy loss on the working, but the progress of that company has been such that all that loss has been wiped out with profits since, and for many years very large dividends have been paid. I do not want to be a prophet,—but it is quite on the cards that that may be the case with this Company. The expenses during this year have been reduced by £6,000, and they are susceptible of still further diminution. They have, however, as I said before, only a certain relation to the output. For instance, for the sake of the argument, suppose we doubled the output this year, the expenses would not be doubled, they would only be increased by the additional driving force—coal, water and oil. That is why the outlook is rather better than might be inferred from a superficial study of these accounts or a superficial application of knowledge. If we had had last year the same number of subscribers as we have now we should have had £6,000 to the good instead of to the bad, which is all the difference; and we must hang on to that hope. We believe it to be thoroughly well grounded. If you will refer to the capital account you will see that there are 111,000 ordinary shares of £5, issued—that is £555,000 paid up. The balance remains to be issued, making up the authorised £1,000,000 of ordinary share capital. Then the £250,000 of preference shares have been created and issued. There are some arrears of calls upon them, amounting to £6,680; but they are practically paid up. By the Articles of Association the Directors may, upon their own discretion, borrow not exceeding £250,000. If they want more than that at any time, they must come to the proprietors to ratify their deeds, but, of course, discreet Directors do not avail themselves of powers of that sort without taking their proprietors into their confidence, and having their concurrence. You see how the capital account has been made up from time to time. It is a very interesting account, inasmuch as it deals with a vast number of items, and we carry forward from year to year those items in order that some day or other, when the Local Authorities take over the electric lighting of these Companies, they may have data as to how the capital has been spent. The revenue account is also, you will see, very full. But now how do we propose to carry on? We have spent all our money, and we have only partially developed the business. Well, the present machinery, upon which we have staked our fortunes, consists of two parts—that which is now at work, and that which has been more or less constructed on the theory that it would be brought into work. We have had to stop any further expenditure that has been already incurred on the second theory, because we have come to the conviction that we had better perfect and found the business upon that part of the machinery which is in work before we proceed further. Now, that machinery existing at this moment at Deptford is capable of lighting 90,000 lamps when the drawbacks I have mentioned, arising from a little want of skill, or want of knowledge in the adjustment of the machinery, is all conquered; and it is being rapidly conquered. We have not quite enough money to carry out our programme. We are in debt, though £20,000 would cover all our indebtedness; and I am sorry to say that the bulk of that arises upon the second part of our enterprise, which is in abeyance for the present—the construction of the two 10,000 H.P. dynamos. We want a little working capital, and we also want to have enough money in hand to develop the existing machinery—to carry it to that state of efficiency which would enable us to light 80,000 or 90,000 lights. We have no money, and it is vital that we should have money, and we have been thinking how we are to get it; and, of course, with a balance-sheet like this, and a result like this of a year's work, with our shares at a heavy discount, it is not very easy to raise money. Therefore, instead of concluding to make any attempt to issue any debentures, we have arranged, subject to your concurrence, to have a loan. Now, there is one peculiarity about this Company which, I think, takes it a little out of the ordinary category. Whether the venture we are all engaged in be carried to a successful issue or not, the preponderating investment in this Company is the investment of your own Directors and their friends. They hold among them two-thirds of the entire paid-up capital. I have often heard it said that the great guarantee for the success of a joint-stock company is that the Directors themselves should hold largely in it. It is a very fortunate thing that, in the existing position of the Company, one of your own Directors should be ready to find this £50,000 that we want for a term of three years, with the option of discharging at our convenience within that time, at 5 per cent. I know of few companies who would find a Director ready to come forward and put himself in that position, and I think the service is a two-fold one. It not only relieves the Company of the possibility of a very bad financial arrangement, but it shows the confidence of that Director in his own property, for he happens also to be the largest shareholder in the Company. That Director, however, will not lend his money except on a mortgage, which will be drawn by his legal advisers and will provide remedies in the event of certain things arising; and, to be quite plain, if that loan is for three years, and at the end of three years this Company's position is such that the loan could not be met—that is to say, if things were so bad that the shareholders themselves or the public would not raise money to pay off the loan—there would be a right to foreclosure. But then, that attaches to every mortgage. It would attach, as you know, to debentures themselves, and I should not have thought it necessary to refer to this matter but for the conscientious scruples of this Director, who thought it ought to be understood that, though he comes forward now in what I may venture to say a liberal handsome manner to help the Company, he is not, because he has done so, to be precluded from the ordinary remedies of creditors at the end of the term if he cannot be paid. With the experience we have had, with most of the difficulties overcome, there seems little reason to doubt—humanly speaking, as it is said—that long before three years have expired we shall be able to issue debentures or make other financial arrangements of such a character as will enable us to discharge this loan. That is all I propose to say except in answer to questions, and I will now move the resolution:

"*That the report and accounts now submitted be approved and adopted.*"

Digitized by Google

Lord WANTAGE seconded the motion.

Mr. PRAED said that as there was a balance of capital in hand at the close of last year of £44,000, and the Company was now in debt to the extent of £20,000, the amount expended during the present year had been £64 000. He wished to know how many lights were now being supplied.

The CHAIRMAN stated that on the 23rd of March they had 423 customers with 36,423 lights, and there were 26 customers waiting for 3,143 lamps. They were now transmitting at 10,000 volts. This gave them some trouble in the early part of the year, and was more or less the cause of the various accidents he had mentioned; but the result of this experience, and the greater development of knowledge on the part of the engineers and electricians had removed what at one time rather disturbed them - a fear whether this high voltage could be maintained. They had now come to the conclusion that it could be maintained, and if so there were great economical advantages about it. It would be a serious drawback to the Company if all the expenditure they had already incurred on the two 10,000 H.P. dynamos had been made in vain. On the other hand one could not blind oneself to the fact that the prevailing opinions of electricians was that small units were more convenient and more economical, perhaps, than large ones. They had sprung from 625 H.P. dynamos into 1,250. They had had some trouble in getting the 1,250 to go to 10,000 volts, but they thought they had overcome the difficulties; and, assuming a sufficient demand for the lighting, they were highly economical and very advantageous; they had some drawbacks, however. Assuming they were lighting 250,000 lamps, a 10,000 H.P. machine, producing enough current for the enormous number of lights, would be a very economical arrangement; but it would be a very costly one in the early hours, when pressure was not on to the full, and also in the later hours when the pressure would be diminished. What might arise was that instead of developing in the direction of these large horses they might find the multiplication of smaller horses a sounder business.

Mr. ADAMS inquired whether the loan of £50,000 was to be secured on the whole of the property, as their assets were very large.

The CHAIRMAN stated that the mortgage would naturally be on the whole of the property, but with respect to its value there were two aspects —the property as it stood in the capital account and its realizable value. Supposing the Company were to break down, for the lender only came upon the security in the event of the Company not being able to meet such a modest sum as £50,000. He did not, however, think that their undertaking was going to break down. In answer to Mr. Hill the Chairman added that they felt sure that the £50,000 would be enough to perfect the present system up to 85,000 or 90,000 lights. They did not anticipate any calamity arising to disappoint this expectation, but they would know all about it within a few months.

Mr. KISCH said that the shareholders had heard many encouraging statements at their meetings about what might be expected in the following year; but they now met with a report which he considered less hopeful than ever before. The property, though it represented considerably over £500,000, did not appear to be over-good security for a £50,000 mortgage, and they had to face the possibility that the whole of the property of the Company might be swept away to satisfy a mortgage for that comparatively small sum. The revenue account showed some startling contrasts compared with that submitted a year ago. He thought that there were no figures giving them ground for hope. Until he came to the meeting he had no idea that further capital was to be asked for. He thought that the Company was "over-officered." From his inquiries, he had gathered that a good deal of the ordering of their stores was vested in the hands of their accountant. Messrs. Savory and Moore had got an injunction against the Company carrying on business at the Grosvenor; and he desired to know how this matter stood, and how the business of the Company would be affected if the injunction should be sustained.

The CHAIRMAN, in reply, said that no stores were purchased without the matter being remitted to a special committee of the Board, and, as far as was possible, everything was got upon tender. No officer of the Company had the slightest voice in determining these matters. As to their general position, what alternative could be suggested by Mr. Kisch, who, he supposed, knew as well as he (the Chairman) did, the reason why last year had been disastrous to the Company? Misfortunes, however, were only to be redeemed by knowledge, and by courage to overcome them; and if the Directors regarded the future of the Company as so hopeless as Mr. Kisch appeared to think, they would tell the shareholders so and advise them to wind up. They were not, however, in that vein. They believed that the Company could be redeemed, but it would only be redeemed by people who had sound information and a clear conception of the remedies for patent faults, not by mere talk. They believed that the remedy was in sticking to the thing and perfecting it up to 90,000 lamps. Mr. Kisch had seemed to blame him for being sanguine, but the world was not carried on by "wet blankets." He founded his sanguineness on his knowledge of difficulties overcome in other things.

Mr. KISCH said he would propose an amendment for appointing a small committee to confer with the Board with a view to reducing the expenditure and getting the Company into a sound and paying position.

The CHAIRMAN, in replying to another shareholder, said that when Mr. Ferranti's agreement came to an end by effluxion of time they had not considered it desirable to continue that gentleman in the position of engineer, inventor and patentee, and contractor. Of course, Mr. Ferranti's agreement did not expire without the Directors taking measures for carrying on the business of the Company. As to the injunction which had been referred to, they had appealed to the Court of Appeal to dissolve it; but whether this application was successful or not, it would not be material to the interests of the Company.

Sir PHILIP MAGNUS said he would second the amendment. They had not, he said, heard who was responsible for their misfortunes, which had led to the present serious diminution in the value of the property of the Company.

Sir THOMAS BAZLEY said that for a long time he was opposed to the theory of the transmission of high voltage, but the more he thought of it the more he was gradually coming to the conclusion that it was right and that the Company's system possessed inherent qualifications which should ultimately make it successful. He visited the Company's works on the previous day, and had been very pleased with all he had seen. The machinery was working with great smoothness. He thought that the expenses required consideration.

The CHAIRMAN said he did not know who was to be the scapegoat for the present state of things; and it would be rather ungenerous, perhaps, to find one. He had been glad to hear the view expressed by Sir Thomas Bazley, who was most competent to judge of a business of this kind, that he was not in despair of the ultimate success of the system of high voltage. He (the Chairman) had had nothing to do with the policy of high tension or anything else; he had only come in as an administrator. He admitted that, in proportion to the results, the establishment charges were very large; but a vast amount of work had to be done which did not appear on the surface. The matter, however, should have full consideration.

On the amendment being submitted to the meeting, it was supported by the mover and seconder only, and the original resolution was subsequently put by the Chairman, who declared it carried unanimously.

Lord WANTAGE then proposed and Mr. Adams seconded the re-election as Directors of Mr. Forbes and the Hon. Reginald Brougham; and the motion was unanimously agreed to.

The CHAIRMAN afterwards stated that it was not necessary to submit a resolution with reference to the loan, and he gathered that the feeling of the meeting was in favour of the proposal.

Messrs. Kemp, Ford and Co. having been re-elected auditors to the Company,

A vote of thanks to the Chairman and Directors brought the meeting to a close.

Sheffield Telephone Exchange and Electric Light Company (Limited).

A special meeting of the shareholders of this Company was held on Wednesday at the Cutlers' Hall, Sheffield, Alderman George Franklin presiding.

The object of the meeting was to adopt and confirm a provisional agreement for the sale to the National Telephone Company of the telephone exchange and telephone business hitherto carried on by the Sheffield Company. The meeting, having been informed of the proposed terms of purchase, unanimously approved of the arrangement. The local Company will now be at liberty to carry on its general electrical business, together with the supply of the electric light, which it has already undertaken, and for which there is an increasing demand, and in connection with which a Provisional Order is now before Parliament, giving the Company increased powers. The terms of purchase by the National Company are such that the shareholders in the Sheffield Company will practically receive a return of the amount expended upon their telephone enterprise.

It may be mentioned that the nominal capital of the local Company is £100,000, with £43,000 paid up. The National Company take over the new telephone buildings at the bottom of Commercial-street, and a portion of the site, the Sheffield Company leasing the remainder of the land for electric light purposes. The National Company have accepted (says the Sheffield *Daily Telegraph*) a stipulation that the rates in Sheffield for telephonic communication shall not be unduly increased, in other words, that the price shall not exceed £10 for the first mile, and proportionately for greater distances.

Mr. William Johnson, secretary and engineer of the Sheffield Company has been retained by the National Company as consulting engineer. The whole of the telephone staff is taken over on the terms now in existence.

International Electric Subway Company (Limited).

The ordinary general (statutory) meeting of this Company was held on Thursday last week, at 12, King William-street, E.C.; Mr. John L. Martin presiding.

The SECRETARY (Mr. Theodore J. Ford) read the notice convening the meeting; and the CHAIRMAN, in the course of his remarks, said this was only a statutory meeting, and therefore the Directors could hardly be expected to have anything very definite to submit to the shareholders, but he would tell them what they had done and proposed doing. In the first place, under the advice of their solicitors, they had completed the purchase of all the patents for the United Kingdom and Europe of the Johnstone system of underground electrical conduits. This system is extensively used in the United States, several hundred miles of the conduits being laid in New York, Chicago, and Philadelphia, and large contracts are now being carried out in other of the principal cities of America. The system has been so extensively adopted in America, because of its economy and permanency, that he did not think it an exaggeration to say that it is the standard system of electrical conduits in use in America to-day. Their system was one by which wires are laid in rectangular iron boxes with interior subdivisions. The upper part of the conduit, as also the lower part, is made in sections of 5ft., so arranged as to break joints at any point where it may be necessary. The wires in the conduits can be made easily accessible without disturbing them or pulling them through long lengths of pipe, and this can be done by simply lifting off the top piece at any point desired. In addition, the man-holes and connections could be put in at any point

Digitized by Google

desired at small cost. The whole of the conduit is made of cast iron, and they were prepared to take contracts and lay our system for the same money as any other system now in use; and the Company claim that they will give for the money very much better results in the way of permanency, safety, and facility of handling and operation. Their energetic managing Director had secured the attendance at their offices of many engineers interested in electrical subway conduits from various parts of England, and had explained their system to them, with the result that the Directors believe they are on the eve of obtaining large and substantial orders in various of the principal towns in England, and even within the precincts of London itself, and also in Paris. A full-sized model of the Johnstone system was on view in the Crystal Palace. It should be remembered that this Company was really a pioneer syndicate, with a capital of only £25,000, and, as their system became more widely known, the Directors believe that they will be able to dispose of their rights on very favourable terms to the various European countries.

A vote of thanks to the Chairman terminated the proceedings; and at an extraordinary meeting subsequently held, the Directors' remuneration was fixed at £250 per annum.

Telephone Company of Egypt (Limited).

The following report has been issued by the Directors of this Company for the year ended December 31 last, and is to be presented at the ninth ordinary general meeting of the Company, to be held at the offices of the Company, 14, Austin-friars, London, E.C., on Tuesday next, the 5th inst., at 12:30 o'clock:—

The revenue account shows a balance to credit of £4,053. 16s. 1d., after payment of debenture interest; adding to this the sum of £1,508. 5s. 5d., brought forward from December 31, 1890, there remains a balance for disposal of £5,562. 1s. 6d., which the Directors propose to deal with as follows:—To pay a dividend of 6 per cent. on the preferred shares, free of income tax; to transfer £525. 18s. 6d. in reduction of capital expenditure; and to carry forward £1,414. 17s.

A small exchange was opened at Suez on July 14th, communicating with Port Thewfick, and although the demand for telephonic service must at these places necessarily be restricted, the Directors are desirous of meeting the public wants in the matter of telephonic communication so far as lies in their power. The support that has been given is sufficient to pay expenses in the meantime, but an extension of the system is hoped for.

At Mansourah, although the terms of subscription were fixed as low as possible, many of the original subscribers had from time to time withdrawn, the demand for telephone inter-communication having been found very limited. Under advice of the Company's manager, the "exchange" service has now been discontinued, but arrangements are in progress with several firms for the rental of some of the existing lines for private use.

On the whole, considering the wave of commercial depression that has passed over the country, the result of the year's business is not unsatisfactory. The profits realised from sales of material, &c., have more than made up for the falling off of revenue at one or two of the smaller branches, and from the accounts now published some doubtful subscriptions have also been excluded.

The gross revenue of the Company at December 31st was £11,263, and the total number of lines, exchange and private, 1,041.

The retiring Director at the present meeting is the Chairman, General Alexander Fraser, C.B., R.E., who, being eligible, offers himself for re-election. Messrs. Price, Waterhouse, and Co., the auditors of the Company, also retire, and offer themselves for re-election.

The House to House Electric Light Supply Company (Limited).

The following report is issued by the Directors of this Company to December 31st last. The meeting takes place at Richmond-road, Kensington, on Tuesday next, at 3 p.m.:—

The revenue account shows a credit balance of £2,250 9s. 1d.; which, with the balance of £385 15s. 8d., brought forward from the previous year, making a total of £2,636. 4s. 9d., is sufficient to cover—

Interest on £30,000 debentures	£1,706	0	0
Ten per cent. to be written off preliminary expenses	542	9	9
Proposed dividend of seven per cent. on £1,710 preference shares	113	9	7
Leaving a balance to be carried forward of..... ..	274	5	5
	£2,636	4	9

During the past year the business of the Company has steadily increased, the number of 35 watt lamps attached to the Company's circuits on the 1st January being 13,665, and on the 31st December, 19,388. At the beginning of the year there were 248 houses connected, and at the end of the year, 373. A special unit of plant has been laid down, by means of which it is not only possible to supply a greater number of lamps, but the lighter load during the period of minimum consumption is more economically dealt with. Important extensions of the Company's mains have also been carried out.

Since the end of the year, the Directors have allotted £12,290 of Seven per Cent. Preference Shares, bringing the total preference capital issued up to £14,000, out of the proceeds of which it is proposed to lay down further plant to enable the Company to cope with its increasing business; and, as the new business will probably entail but little addition to the standing charges, it may be confidently anticipated that the profits for the current year will show a substantial improvement on those of 1891.

An agreement, which, it is hoped, will in future provide a satisfactory addition to the profits earned at the West Brompton Station, has been entered into with the Leeds and London Electrical Engineering Company (Limited), by which agreement that Company will carry on the business built up by the Company for the construction of central stations.

The following is a comparative statement for the past two years:—

Working Expenses.		——	Revenue.	
1890.	1891.		1890.	1891.
£1,921 0 7	£3,118 2 9	Jan. 1 to June 30	£1,373 6 7	£3,838 0 6
£2,703 5 10	£2,889 12 5	July 1 to Dec. 31	*£3,637 2 7	£4,490 3 5
£4,624 6 5	£6,007 15 2		£5,010 9 2	£8,328 3 11

* Very foggy December.

The Directors have drawn no fees during the past year, but £200 has been paid to Mr. William Page, for special services. They congratulate the shareholders upon the promising position of the Company's business. Thanks are due to the manager and staff, who have so materially aided in placing the working of the enterprise on a satisfactory basis.

During the past year Mr. W. F. Leese and Mr. Joaquin de Galindez have been elected Directors, and their election is now brought forward for confirmation by the shareholders. Mr. H. R. Beeton and Mr. Robert Hammond retire by rotation, and offer themselves for re-election. Messrs. Theobald Bros. and Miall, the auditors, retire, but, being eligible, offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "The Electrician" Electrical Trades Directory and Handbook, 1892, pages 308-322, *&c., &c.*]

ASSOCIATION FOR THE PROTECTION OF TELEPHONE SUBSCRIBERS (LIMITED).—At last telephone subscribers are to be "protected," and our readers will enjoy the humour of the following registration. It will be noticed that among the subscribers are a wine and spirit merchant, a wholesale druggist, a chartered accountant, an electrical engineer, a colonial broker, a Mincing-lane merchant, and, to savour the whole, a solicitor. If telephone subscribers are not sufficiently "protected" with such a representative body as this, what hope can there possibly be? The Association was registered on the 25th March as a company limited by guarantee by, we understand, Messrs. Hasties. For the purposes of registration, the number of members is declared to be 20, and each of these undertakes to contribute to the assets of the Association, in the event of winding-up while he is a member or within a year afterwards, a sum not exceeding £1. Amongst the objects are: To "assist and protect" telephone subscribers in the United Kingdom, and particularly those of London and its neighbourhood. The subscribers are:—

C. R. Haig, 12, Mark-lane, E.C., *wine and spirit merchant.*
Charles G. Clarke, 5, 6, and 7, Raven-row, E., *wholesale druggist.*
William C. Jackson, 58, Coleman-street, E.C., *chartered accountant.*
Frederick Lawrence Rawson, 88, Queen Victoria-street, E.C., *electrical engineer.*
H. R. Oscar Thompson, 38, Mincing-lane, *colonial broker.*
C. Hubert Hersey, Dunster House, Mincing-lane, *merchant.*
A. H. Hastie, 65, Lincoln's Inn Fields, *solicitor.*

Until Directors are appointed, the subscribers shall, for all purposes, be deemed to be Directors.

BLACK, HAWTHORN, AND CO. (LIMITED).—This Company was registered on March 23, 1892, with a capital of £110,000, in £10 shares, by Jordan and Sons, 120, Chancery-lane, London, W.C. The objects are to acquire and carry on the business of builders of locomotive, marine, and stationary engines, and of general engineers, and manufacturers of, and dealers in, iron work, carried on by William Black and others at Gateshead-on-Tyne, under the style of Black, Hawthorn, and Co.; to carry on the business of engineers and makers of, and dealers in, iron, steel, brass, copper, &c., general merchants, and mechanical, electrical, and chemical engineers, and "to carry on any business or businesses directly or indirectly connected with the generation, accumulation, distribution, supply, or application of electricity."

PONTYPOOL ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—This Company was registered on March 28, 1892, with a capital of £10,000, in £5 shares, by Waterlow Brothers and Layton (Limited), 24 and 25, Birchin-lane, E.C. The objects are to generate, produce, store, accumulate, distribute, and supply electrical energy, or other similar energy, whether in the form of light or motive power, in and to streets, public places, public and private buildings, manufactories, mines, railways, tramcars, or other places, or to generate, supply, and sell such electrical energy for the purpose of plating, combining, separating, or otherwise working in metals, or for carrying out or facilitating any mechanical operation; and to erect, construct, lay down, manufacture, and maintain all such generating stations, works, mains, electric lines, and other appliances as may be considered necessary; to acquire the right to use or manufacture and put up telephones, telegraphs, electric bells, phonographs, and all electrical apparatus. Amongst the subscribers are:—

	Shares.
Mr. William Pegler, Jun., George-street, Pontypool, merchant	100
Jno. C. Howell, 24, Queen Victoria-street, London, E.C., electrical engineer	100

The first Directors are W. Pegler, Jun., E. B. Ford, W. Sandbrook, J. Herbert, and J. C. Howell.

BERNSTEIN ELECTRIC LAMP COMPANY (LIMITED).—The annual return of the above-named Company, made up to December 31, 1891, was filed on March 15, 1892. There has been no annual meeting held for the year 1891. The Company was registered on July 29, 1885, with a capital of £100,000, in £10 shares, to purchase the British Letters Patent, No. 2,604 of 1882, No. 6,075 of 1882, and No. 3,915 of 1883, and the patents for the inventions, or some of the inventions, protected by such British letters patent, obtained or applied for by Alexander Bernstein in and for Belgium, Denmark, Sweden and Norway, and Russia respectively, and to carry on the business of manufacturers of and dealers in apparatus for producing and supplying electricity, whether for the purpose of lighting or otherwise. An agreement dated August 1, 1885, with J. T. Brunner, Julius Maier, A. Bernstein, and Ludwig Mond determined that in consideration of the above-mentioned patents, all of which were for "Improvements in Incandescent Electric Lamps," £11,000 in fully paid-up shares be allotted as follows:—J. T. Brunner, 150 shares, numbered 10 to 159 inclusive; Ludwig Mond, 150 shares, numbered 160 to 309 inclusive; Alexander Bernstein, 600 shares, numbered 310 to 909 inclusive; and Julius Maier, 200 shares, numbered 910 to 1,109 inclusive. A royalty of 2½d. for every lamp constructed by the Company or any licence of the Company was to be paid half-yearly to the said A. Bernstein. At the time of making up 2,814 shares had been taken, and, according to the return, the full amount called and all calls (£28,140) paid. This, however, does not give any account of the shares issued as fully paid in accordance with the above agreement. The principal shareholders are Alexander Bernstein, electrician, of Mühlenkamp, Hamburg (1581); J. T. Brunner, alkali maker, of Winnington Hall, Northwich (400); and Ludwig Mond, chemist, of 20, Avenue-road, London, N.W. (801). Registered office: 40, Chancery-lane, London, W.C.

BISHOP'S STORTFORD ELECTRIC LIGHT AND STEAM LAUNDRY COMPANY (LIMITED).—The annual return of the above-named Company, made up to February 26, 1891, was filed on March 11, 1892. The annual return was also filed on March 11, 1892. No change has been made. Registered office: North-street, Bishop's Stortford.

CITY OF BATH ELECTRIC LIGHTING AND ENGINEERING COMPANY (LIMITED).—The first annual return of the above-named Company, made up to March 12, 1892, was filed on March 19th. At the time of making up, 3,246 ordinary and 50 founders' shares had been taken up, of which 2,250 ordinary and 50 founders' shares had been issued as fully paid. (It will be noticed that only 2,250 ordinary shares are here said to be issued as fully paid, and no notice of the change has been given to the authorities.) Upon the remaining 996 ordinary shares the full amounts have been called, resulting in the payment of £9,835, and leaving £125 in arrears. The principal shareholders are the Brush Electrical Engineering Company (Limited), 49, Queen Victoria-street, E.C. (600 ordinary and seven founders' shares), Emile Garcke (50 ordinary), Laing, Wharton and Down Construction Syndicate (Limited), 82A, New Bond-street (216 ordinary and four founders' shares); Alfred Pitman (100), Ernest Pitman (100), and Isaac Pitman and Sons (160), all of 12, Royal-crescent, Bath; Henry G. Massingham, of Bath (504 ordinary and 33 founders' shares); Colonel A. S. Haghan, of Norwood (50 ordinary); E. B. Titley, of Bath (250 ordinary); Lieutenant-Colonel T. Vaughton, of Bath (60 ordinary); Callender's Bitumen Telegraph and Waterproof Company (Limited), of 101, Leadenhall-street (550 ordinary and six founders' shares); and E. Garcke and T. O. Callender jointly (100 ordinary).

CITY OF WESTMINSTER ELECTRICAL SYNDICATE (LIMITED).—The annual return of the above-named Company, made up to December 31, 1891, was filed on March 16, 1892. The Company was registered on July 11, 1888, with a capital of £10,000, in £1 shares. At the time of making up (31st December, 1891), the 10,000 £1 shares had been taken up, the full amount called and all calls paid. A note on the return states "That no meeting was held during 1891, the syndicate having been acquired by the Westminster Electrical Supply Corporation (Limited), and it is now in the process of voluntary liquidation."

ELECTRICAL ACCESSORIES COMPANY (LIMITED).—The annual return of this Company, made up to January 14, 1892, was filed on March 15th. The Company was registered on September 28, 1889, with a capital of £5,000, in £1 shares. At the time of making-up, 1,957 shares had been taken up, of which 1,500 had been issued as fully paid in accordance with the above-mentioned agreement. Upon the remaining 457 shares, the full amount has been called, and all calls have been paid. Another return, made up to February 15, 1892, was also filed on March 15th, 2,257 shares had been taken up, of which 1,500 had been issued as fully paid. Upon the remaining 757 shares the full amounts had been called and all calls paid. In the former return B. M. Drake, of 66, Victoria-street, S.W., electrical engineer, held 1,503 of the 1,957 shares taken up, but these have been transferred. Mr. C. L. Schwind is now Managing Director.

KESWICK ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of the above-named Company, made up to March 12, 1892, was filed on March 21st. The Company was registered on May 1, 1889, with a capital of £5,000, in £1 shares. At the time of making up, 3,420 shares had been taken up, and upon 2,355 of these the full amount had been called, while upon the remaining 1,065 shares, 10s. per share had been called, resulting in the payment of £2,887. 10s. The majority of the shares are taken up by the residents of Keswick and district.

NONPAREIL ELECTRIC SYNDICATE (LIMITED).—The annual return of the above-named Company, made up to December 31, 1891, was filed on March 23, 1892. The Company was registered on August 13, 1890, with a capital of £6,000, in £10 shares. At the time of making up 400 shares had been taken up, of which 200 had been issued as fully paid; upon the remaining 200 shares the full amount had been called, and all calls (2,000) had been paid. Registered office: 2, Victoria-mansions, Victoria-street, Westminster, S.W.

NORTHAMPTON ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company, made up to March 10, 1892, and filed on March 21, 1892, shows that out of a capital of £50,000, divided into 10 "A" and 49,990 "B" shares of £1 each, 10 "A" and 10,000 "B" shares have been taken up. The full amount had been called and paid on the "B" shares, while upon the "A" shares no calls have been made.

RAILWAY AUTOMATIC ELECTRIC LIGHT SYNDICATE (LIMITED).—The annual return of the above-named Company, made up to February 15, 1891, was filed on March 11, 1892. The Company was registered on February 26, 1889, with a capital of £10,000 in £25 shares. At the time of making up all the shares had been taken up, of which 200 had been issued as fully paid. Upon the remaining 200 shares £15 per share had been called resulting in the payment of £2,886, and leaving £114 in arrears.

SHIPPEY BROTHERS (LIMITED).—We have received the following from this firm:—Summary of capital and shares made up to December 31, 1891. Nominal capital, £30,000, divided into 6,000 shares of £5 each; number of shares taken up to December 31, 1891, 2,412; called up on 612 shares, £3,060; total amount of calls received, including payment on application and allotment, £3,060; total amount agreed to be considered as paid on 1,800 shares, £9,000; total amount of calls unpaid, nil.

SUNBEAM LAMP COMPANY (LIMITED).—The annual return of the above-named Company, made up to February 12, 1892, was filed on February 22nd following. The Company was registered on December 13, 1887, with a capital of £25,000, in £10 shares, to manufacture, sell, and deal in incandescent electric lamps. At the time of making up, 2,213 shares had been taken up, of which 2,000 had been issued as fully paid. Upon the remainder the full amount has been called, resulting in the payment of £2,100, and leaving £30 in arrears.

TAUNTON ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of the above-named Company, made up to March 14, 1892, and filed on March 18th, shows that out of a capital of £20,000 in £5 shares, 2,569 have been taken up and 787 have been issued as fully paid. Upon the remaining 1,782 shares the full amount has been called, and all calls (£8,910) have been paid.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LTD).—The annual return of the above-named Company, made up to March 15, 1892, was filed on March 24, 1892. The nominal capital is £448,200, divided into 37,350 shares of £12 each. All the shares have been taken up, the full amount called, and all calls (£448,200) paid.

WINDSOR AND ETON ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of the above-named Company, made up to March 11, 1892, was filed on the same day. The Company was registered on November 24, 1888, with a capital of £20,000, divided into 5,950 ordinary shares of £5 each, and 250 founders' shares of £1 each. At the time of making up, 250 ordinary shares had been taken up and the full amount called, resulting in the payment of £1,192, and leaving £58 in arrears.

CITY NOTES, &c.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—An interim dividend has been declared by the Directors of this Company for the quarter ending 31st March, 1892, of 12s. 6d. per cent. on the ordinary stock, and 25s. per cent. on the preferred stock, less income tax, payable on the 30th April to the stockholders registered on the books of the Company on 31st March, 1892.

CALLS DUE.—15s. (final) on ELMORE'S AMERICAN AND CANADIAN PATENT COPPER DEPOSITING COMPANY'S £2 Priority shares (*April 1*).

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended March 27th were £618, as against £702 in the corresponding period of last year, showing an increase of £116. The total receipts to date, from January 1, 1892, are £10,545, against £9,183 for the corresponding period of 1891, an increase of £1,362.

DIVIDENDS DUE.—*April 1*, COMMERCIAL CABLE COMPANY, quarterly div. at the rate of 7 per cent. per ann. (less income tax); DIRECT SPANISH TELEGRAPH COMPANY, 4 per cent. for half-year (eq. 4½ per cent. for year to Dec. 31, 1891); *April 14*, EASTERN TELEGRAPH COMPANY, interim of 2s. 6d. per share (eq. 10 per cent. per annum) for quarter ended Dec. 31, 1891. *No date fixed*, KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY, 2 per cent. for year ending Dec. 31, 1891 (less income tax); ORIENTAL TELEPHONE COMPANY, 2¼ per cent. for year to Dec. 31, 1891 (eq. to £3. 12s. 2d. per cent. for year on ordinary shares, 11s. paid).

EVERED AND CO.—The Directors of this Company recommend that, after providing for debenture interest amounting to £2,437, a dividend at the rate of 7½ per cent. per annum be paid for the six months ended 31st December, 1891, making 7½ per cent. for the year; and also that a bonus be paid for the year of 2½ per cent., that £1,000 be written off plant, &c., and £3,000 placed to the reserve fund (making it £23,000), and that £3,325 be carried forward to the next account.

FAREHAM ELECTRIC LIGHT COMPANY (LIMITED).—The annual general meeting of the shareholders of this Company was held recently at the Red Lion Hotel, Fareham. The Directors' report showed that the past year's working, after providing for interest on the debenture bonds, precluded the paying of any dividend on the ordinary shares of the Company. The report states that the public lighting of the principal streets met with the general approval of the inhabitants, and had been most favourably

Digitized by Google

reported on by deputations from Blackpool and elsewhere. The report also stated that the duplicate plant would be in running order within a few days, and then any little irregularity in lighting that occurred in the past would be avoided. The balance-sheet to December 31st last showed capital and liabilities: 4,158 shares (£1 called), £4,154; arrears of calls, £4; debentures, £2,295; debts due to tradesmen for supplies of plant, stock-in-trade, and other articles, £455. 13s. 7d.; interest on debentures, £20. 5s. 10d.; total, £6,928. 19s. 5d. Property and assets: Electric light station, £350; stock-in-trade, £123. 0s. 2d.; plant, £5,363. 14s. 7d.; debts considered good, for which the Company hold no security, £273. 18s. 11d.; cash at National Provincial Bank, £234. 16s. 1d.; cash in hand, £39. 16s. 11d.; balance forward December 31, 1890, £149. 1s. 6d.; loss, £394. 11s. 3d.; total, £6,928. 19s. 5d.

W. T. HENLEY'S TELEGRAPH WORKS COMPANY (LIMITED).—The thirteenth general meeting of this Company was held on Thursday, March 24, and we have received a notification from the Company that the report and accounts for the year ended December 31st last were adopted unanimously. After writing off £6,757 from ship gear and patents, and providing £10,000 in reduction of "B" debentures, dividends at the rate of 7 per cent. per annum on the preference shares, and 5 per cent., free of income-tax, on the ordinary shares, were declared, and a balance of £11,731 carried forward to current year's account.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ending March 25, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,106.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 725.—Vol. XXVIII. FRIDAY, APRIL 8, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The case of King, Brown and Co. *v.* The Anglo-American Brush Electric Light Corporation came before the Court of Session in Edinburgh on Tuesday, November 27th, 1888 (*The Electrician*, Vol. XXII., p. 111). Judgment was delivered by Lord Trayner for the plaintiff with costs on Wednesday, June 26th, 1889 (*The Electrician*, Vol. XXIII., p. 200). Against this judgment the Brush Corporation reclaimed to the First Division, that is, appealed. The Lord President and Lords Adam and McLaren on Wednesday, July 16th, 1890, upheld the judgment of Lord Trayner with costs (*The Electrician*, Vol. XXV., p. 291). On Tuesday last, April 5th, 1892, the Lord Chancellor, Lord Watson, and Lord Herschell delivered judgment in the House of Lords, Lords Macnaghten and Field concurring, affirming the judgment in appeal. Their Lordships' judgments will be found in full elsewhere in the present issue.

The truly gigantic contract for the arc lighting of the Chicago Exhibition has given rise to a squabble of appropriate dimensions. Tenders were asked by the Bureau of Construction for the supply of dynamos and auxiliary apparatus sufficient to run 6,000 2,000 c.p. arcs. On March 15th a committee assembled to find that only one tender—that of the Thomson-Houston Company—was really before them. This Company offered to furnish the lights for $38\frac{1}{2}$ per lamp, which would mean $231,000 or £46,200 for the arc lighting of the entire Exhibition. The Western Electric Company had indeed offered to be responsible for 500 lights at $31\frac{1}{4}$ each, but did its best to withdraw this offer before the tender was opened. As the Exhibition authorities had been led by a representative of the Edison Company to anticipate a charge of only $15 per lamp, and by a representative of the Thomson-Houston Company itself a charge of not more than $20, the demand for nearly double the latter sum was "peremptorily rejected."

There are two sides to every question. The Exhibition authorities consider the price demanded an exorbitant one, and declare that the Electrical Companies have wickedly combined to "sandbag" the Fair, whatever that may mean. One eminent gentleman has indeed unbosomed himself to a reporter thuswise: "The idea of the Edison Company refraining to come in on a contract as big as this is enough to make us all sick. It indicates, too, we think, that the big companies have struck hands and divided up the work to be done on some basis satisfactory to themselves."

The Thomson-Houston Company, on the other hand, denies all idea of extortion, and marshals a formidable array of facts and figures to show that its charge is astonishingly moderate, considering the conditions imposed. The task of lighting the Chicago Exhibition by arcs is, in its opinion, "something beyond the capacity of any other firm on the face of the earth, and the nerve in submitting an estimate for the entire installation is something that should receive due credit."

This way of looking at the matter has, however, failed to commend itself to the Bureau of Construction, whose representative is now on his way to Europe, "to confer with the manufacturers of electrical machinery in reference to lighting the World's Fair." It is to be hoped that the net result of all this pother will be the installation of some fine samples of English central-station practice on the shores of Lake Michigan.

In a report to the Electric Lighting Committee at Bath, Mr. Gatehouse states that the public arc lamps were properly described as 1,200 c.p., though they did not give an effective candle-power of 1,200 candles as used in the streets, surrounded with ground glass or opal globes. The inhabitants of Bath are to be congratulated on having lamps which actually emit their nominal candle-power; these are almost as rare as reputed pints which will hold 20 fluid ounces. Mr. Gatehouse found that ground-glass globes, when clean, absorb 42 to 46 per cent. of the light, and opal globes from 54 to 70 per cent., and absorbed a larger percentage than that when not properly cleaned. These figures are rather high. A 70 per cent. globe is not rare; but, as a rule, no one but a gasfitter would think of supplying them. Ground glass may absorb less than 20 per cent., and generally ranges between 25 and 30 per cent. Prof. Forbes has stated that "little if any light was necessarily lost by the use of frosted bulbs, and what was absorbed was due to the dirt which the frosting collects." This statement caused some surprise at the time; but we have since heard from the same authority, under oath, that a difference of 15 volts on an 85-volt lamp would make no difference in the light perceptible to any one but an expert, and that most people not electricians would not notice it.

Digitized by Google

How far these statements agree with general experience it is not necessary to discuss, but they are fairly in accord with each other. One of the most agreeable kinds of globe has a thin layer of opal glass "flashed" on a clear body, and then frosted or etched. Nothing is more difficult to clean than the old-fashioned ground glass. A maximum of 30 per cent. should never be exceeded for arc lights.

Nearly six months ago we commented on the regulator socket for glow lamps, and pointed out that there could be no perceptible saving in its use, and what saving was effected at the lamp would fail to be recorded on most meters. Further particulars of this socket have recently been published, and the results of some tests of it will be found in another column. By the so-called efficiency of the arrangements is meant the ratio of the total watts used in the filament to the total watts given to the lamp. But this efficiency has little to do with the use of the socket for electric lighting, and can only be applied to its use in connection with heating or warming.

We have calculated the cost of the lighting with a regulator socket, assuming that a 16 c.p. lamp costs 8d. for 15·6 hours, giving, say, 2,500 c.p. hours. When the switch is turned to contact No. 1 the light of an ordinary Edison Swan lamp would drop to 9·7, or 60·5 per cent. If the reduction in light were made by a thick shade, the current remaining the same, the cost per candle hour would be nearly double, *i.e.*, 1s. 1½d. There is, however, with the Ries regulator, a saving of 8·2 watts, or 14 per cent. of the energy, which brings the cost to 11·4d. The cost per lamp, reckoned by time only, neglecting the light, would be about 6·9d., as against 8d. Say half the light turned off and only one penny saved. The switch being turned to No. 2, the light of a 16 c.p. lamp would be about 5·6. About two-thirds of the light would be shut off, and the saving per lamp would be 2d. with a meter reading true watts, or 1·4d. if apparent watts were recorded. The cost of 2,500 candle hours with the switch at No. 2 would, with a true meter, be 1s. 5¼d. while if the light were merely cut off by a shade, the current remaining the same, the cost would be nearly 1s. 11d. The efficiency of a choking coil if used for electric lighting should take into account the efficiency of the lamp. Choking coils may no doubt be useful for many purposes, and their design and efficiencies have at present received very little attention.

We publish this week a valuable investigation by Prof. J. J. Thomson on the effect of eddy currents in modifying the distribution of the lines of force in the iron cores of transformers; and in our next issue we shall be able to place before our readers several numerical results worked out by Prof. Ewing. The eddy currents exert a demagnetising influence on the core, and cause the lines of force to crowd together at the surface of the iron, just as alternating currents in a thick conductor tend to confine themselves to the outer conducting layers. The magnitude of this effect is quite startling when the iron plates are not finely laminated, as Prof. Ewing calculates that with plates two millimetres thick the density of the lines of force at the surface is 10 times as great as in the middle portions of the iron.

In this issue appears an important Paper by Dr. Hopkinson and Mr. F. Wilson on dynamo-electric machines. The Paper is full of valuable matter stated in a concise way, and, like all the work with which Dr. Hopkinson is connected, it merits the closest attention. It forms the completion of the well-known Paper on Dynamos, presented by the Brothers Hopkinson to the Royal Society in 1886. On that occasion the influence of the re-actions of the armature were not fully considered, and the present investigation has consisted in applying the law of the magnetic circuit, first put into practical shape by Kapp and Hopkinson, to the local circuits in the neighbourhood of the armature core. The verification of this law has been carried out in a highly successful manner, with the result that the cross magnetisation caused by the currents in the armature is exhibited in a much clearer light than has hitherto been possible.

The committee of experts of the Crystal Palace, having no funds worth mentioning at their disposal, have issued a circular to exhibitors, signifying their willingness to witness any approved tests or experiments which they (the exhibitors) care to make. The committee will, we understand, invite the jury, who apparently have no voice in the matter, to consider these tests, with the view of making their awards. In order, we suppose, that the jury may have a quiet time, they are summoned on April 9th, when they will be undisturbed by sightseers who will be at the Boat Race. The first meeting of the jury was held simultaneously with, and within a few yards of, Herr Joachim's recital. Fortunately, this sort of thing cannot detract from the splendid success of the Exhibition.

When we first heard that the City of London Electric Lighting Company were going to adopt the transformer sub-station system, it occurred to us that there might be some difficulty in finding suitable sites; but difficulties are only made to be overcome. The churches of St. Bene't Sherehog and St. Nicholas Acons, both victims to the Great Fire, have churchyards, and these churchyards have vaults, and vaults are just the very thing for transformer sub-stations. Although the churches no longer exist, the rector and churchwardens, like the King, never die. Hence they have petitioned, as chronicled in another column, to be allowed to rent portions of the churchyards to the City of London Electric Lighting Company for the purpose of constructing transformer sub-stations therein.

Tanning by Electricity.—An electric tannery has been started at Verviers (Belgium).

The General Electric Power and Traction Company.—We understand that Mr. Robert Macpherson, late general manager to the Company, has resigned his position.

Toynbee Hall.—The next of the Science Conferences will be held on Wednesday, April 13th, when a Paper will be read on "Electrical Installations," by Mr. Reginald J. Jones.

Digitized by Google

Storage Batteries for Telegraph Purposes.—At the Vienna central telegraph office there are at present 4,000 Daniell and 600 Meidinger cells in use, and it is proposed to replace them all by a battery of storage cells.

The Telephone at Cassel.—An impatient subscriber to the Cassel telephone exchange, who was moved by telephonic dilatoriness to send the epithet "sluggard" along the wires, has been condemned to pay a fine of £1 and costs.

University College, Bristol.—Courses on civil engineering, mining engineering and electrical engineering will be held during the third term, commencing April 26th. Further particulars will be found in our advertisement columns.

Copper in Madagascar.—It is announced that several rich copper deposits have recently been discovered in Madagascar. It is further reported that the new veins are so advantageously placed for shipping that at present prices it would pay well to work them.

Athens.—At the close of 1892 the lamps connected on to the Athens Electric Light Company's mains comprised 94 arcs and 4,164 incandescents. Current is supplied for motors to seven printing shops, the National Bank, and two other establishments.

The Metropolitan Electric Railway Schemes.—The five following lords have been named to join with the Select Committee of the House of Commons appointed to consider the Metropolitan Electric Railway schemes, viz., Lord Lauderdale, Lord Strafford, Lord Barrington, Lord Thring, and Lord Kelvin.

Industrial Applications of Electricity.—In May the Minister of Agriculture will open in Paris an International Exhibition connected with the alcohol trade. An entire section is to be devoted to electricity applied to brewing and similar purposes. The various electrical processes for rectifying spirit, and ageing wine and beer, &c., will be shown in operation.

Interurban Telephony.—Telephonic communication between Exeter and Plymouth was established this week by the Western Counties and South Wales Telephone Company. At the same time the intermediate towns were put into communication with these large centres. On Tuesday last the National Telephone Company opened the Belfast-Dublin line.

Coast Communications.—Sir Edward Birkbeck has added to his resolution with regard to coast communications, which has the first place for Tuesday, 26th inst., words declaring in favour of the appointment of a Royal Commission to consider the question of connecting certain lightships and outlying rock lighthouses with the shore by means of cable communication.

Siemens and Halske Telephone Cable.—According to the *Elektrotechnische Zeitschrift* Siemens and Halske are now turning out a lead-covered telephone cable for the Bavarian Government on the Fortin-Hermann plan, the dielectric being air. The insulation resistance is 100 megohms per kilometre at 15°C., and the electrostatic capacity is 0·08 to 0·09 microfarad per kilometre.

Personal.—Mr. J. F. C. Snell, has been appointed engineer to the Albert Electric Lighting Company. Mr. Snell was for several years with Messrs. Crompton and Co. as one of their assistant engineers on central-station contracts at home and abroad, and has been acting for the last few months as electrical inspector to the Directors of the Crystal Palace.

Electric Traction at Gera.—The electric tramway laid down by the Allgemeine Elektricitäts Gesellschaft is now in operation. An overhead wire is used as on the same Company's line at Halle. Fourteen cars are running, and when the traffic requires it each of these can take another in tow. The heavy grades (1 in 20 and 1 in 23) are easily mounted, and the line is becoming very popular with the inhabitants.

Milan.—We learn from *L'Elettricita* that the Municipal Council of Milan is examining several proposals for lighting the town, the contract with the Edison Company being about to terminate. It is said that this Company is prepared to reduce their charges both for public and private lamps, but that an offer has been received from Berlin, the terms of which are lower than those last named by the Edison Company.

Electric Traction in Ceylon.—It is, says *Indian Engineering*, proposed to construct an electric railway from Nanuoya to Nuwara Eliza; power will be obtained from a waterfall. The line is as nearly as possible four miles long, and the rise in elevation is about 900ft., giving a uniform gradient of 1 in 23. By lengthening the line to six miles, however, rounding some of the mountain valleys, a grade could be obtained workable after the ordinary fashion.

The Lighting of the Frankfort Exhibition.—The number of arc lamps employed in lighting the Frankfort Exhibition amounted to 880, with 15,740 incandescents. Inside the Exhibition 10 tons of bare copper and 20 tons of cables were laid down. In connection with the Palmgarten installation, 88 tons of bare copper and 20 tons of cable were used. In the Offenbach transmission 8 tons of bare copper, and in the Lauffen transmission 60 tons of bare copper were used.

Copper.—The statistical position of copper, according to Messrs. H. R. Merton and Co.'s monthly report for February, shows that the stocks in England and France and afloat thereto are smaller than they have been for the last three years. The stocks are now 54,311 tons, as against 56,781 tons on February 29th. While the supplies amounted to 8,335 tons during March, the deliveries were 10,805 tons, thus accounting for the reduction in stocks. At this time last year the stocks were 60,253 tons, and on March 31, 1890, as much as 91,938 tons.

A Long-lived 32-c.p. Lamp.—Mr. H. J. Wells, superintendent of the Osceola Light Company, Osceola, Pa., reports, says the *Electrical World*, that a Sawyer-Man lamp on one of the circuits of that Company has just closed a remarkable record. The lamp in question was constructed for an E.M.F. of 110 volts, and was run as nearly as possible at that voltage. Its normal brilliancy was 32 c.p. The lamp was placed in circuit February 22, 1889, and remained in service with an average use of 8½ hours per day until March 5, 1892.

Stealing Electricity.—According to the *Engineering Record*, a St. Louis Court has before it a novel case for adjudication. An electric light and power company brought suit for theft of electricity by bridging wires entering a store before the wires entered the meter. The defendant raised the point that electricity cannot be stolen, inasmuch as in order to constitute stealing there must be an *asportation*, a condition impossible in the case of electricity, which, not being in any wise under control, is therefore not the goods, property, or effects of anyone.

Maritzburg (Natal).—The Town Council have commissioned Mr. R. Lewis Cousins to investigate and report upon the water-power available in the vicinity of Maritzburg for light and power purposes. The most accessible and promising falls are the celebrated Howick Falls, reputed to be the second highest in the world, and the falls at Edendale and the Lower Umgeni. The Edendale Falls, which are some 60ft. high, are eight or nine miles from Maritzburg, and can furnish about 750 H.P. when the streams are moderately full. The Howick Falls are 364ft. high, and 11 miles from the town.

Glasgow.—We hear on reliable authority that the Contract Committee of the Town Council have decided to recommend the acceptance of Messrs. Latimer Clark, Muirhead and Co.'s electric lighting tender.—The Electric Lighting Sub-Committee of the Glasgow Gas Trust have agreed to recommend that, on and after May 31st next, the charge for electricity supplied from their central stations shall be reduced to 7d. per Board of Trade unit. The price charged hitherto, by both Messrs. Muir, Mavor, and Coulson, and by the Corporation has been 8d. per unit.

The Overland Trolley System in the States.—The rapidity of the introduction of the overhead trolley system has been extraordinary, says the *Electrical Engineer* of New York, and can only be accounted for on the supposition that it meets and

Digitized by Google

fills one of the greatest wants of modern American communities. Of the 16 cities of the United States having over 200,000 inhabitants, 14, or 87 per cent., are equipped with electric roads. Of the 42 cities having between 50,000 and 200,000 inhabitants, 41, or 97½ per cent., have electric roads. Of the remaining 391 American cities that have a population over 8,000 we do not know of a score that have not an electric road or serious plans for establishing one.

Pole-Indicators.—*L'Electricien* is responsible for the following recipes for pole-indicator solutions. For placing inside a glass tube corked at either end and provided with adjustable electrodes:—50 grammes of glycerine, 3 grammes of saltpetre, 20 grammes of water, 0 5 gramme of phenol phtalein dissolved in 10 grammes of alcohol. The *negative* pole is surrounded on the passage of a current with a violet-red aureole. Paper cut into short strips may be used as pole-indicators if dipped into a bath composed of 250 grammes of saltpetre, dissolved in a litre of water (8¾oz. to 1 quart), then dried, and finally soaked in a solution of 5 to 6 grammes of phenol phtalein dissolved in alcohol. If the last treatment is replaced by any of the following, we get the results set forth:—

	Colouration.	Pole.
Rosolic acid (neutralised)	Violet ...	Negative
Methyl violet	Blue-green...	Positive
Tropælin OO, or orange No. 4 of Poirier	Bright red...	Positive
Orange No. 3. (These two have a Diphenylamine base)	Bright red...	Positive
Orange No. 1. or No. 2 (Naphtol base)	Red ...	Negative

Litmus paper can also be made use of as a pole-indicator.

Water Power for Electrical Purposes.—In reporting on a proposed new storage reservoir at Plymouth, the water engineer (Mr. Sandeman) states that one could be constructed at Burrator. Here one could be formed, with a capacity of 422 million gallons, for £96,000. The reservoir could be designed so that, when requisite, its storage capacity could be increased (at small cost) by 350 million gallons by raising the dams 10ft. higher, making the total storage capacity 800 million gallons. Dealing with the question of water power, Mr. Sandeman says, assuming the town to be in possession of storage capacity sufficient to ensure a daily supply of 6 million gallons, the energy available by utilising the fall from one reservoir to another would give a total gross H.P. of 464; and after deducting the friction in the pipes, turbines, &c., a net H.P. of 175. It should be remembered, observes the engineer, that this power is continuous through the 24 hours; and if it be found advisable at some future time to introduce into the town the system of supplying water-power at high pressure (600 or 700lb. per square inch), for the use of small traders and manufacturers in place of steam-power, the means of producing hydraulic power by day and electric light by night are here present.

Ascertaining Distances and Directions at Sea.—The necessity for some means of finding the direction and distance of another ship at sea, especially in fogs, gives much interest, says the *Engineer*, to the following method of measuring distances at sea, devised by Mr. H. P. Dowling, of Cardiff:—It consists essentially in the employment of apparatus for sending sound signals simultaneously through air and through the water; and apparatus for receiving and registering the sound so sent, so that the difference in time of arrival through both media may be used to indicate the distance. Duplicate sounds could be produced by the detonation of gunpowder, gun-cotton, or by double bells, double syrens, &c. The receiving apparatus would consist of pairs of similar vibrating diaphragms, one of each pair being situated in the sea, and the other in the air vertically over the first. The vibrations of these plates would be used to work an electric contact-breaker, and thus cause the sound-signals to automatically control a registering instrument. The registering apparatus would have a system of electro-magnets and armatures, actuating pencils pressing on the surface of a strip of moving paper. The clockwork would make marks at regular intervals on the paper. If these marks were made at intervals of 3·6 seconds, or fractions of that time, the distance could be read at a glance, in miles or fractions thereof. The interval of 3·6 seconds is arrived at on the assumption that sound travels 1,100ft. in air and 4,400ft. in water per second. One pair of receiving instruments would serve to determine distances in a line at right angles to the plane of the diaphragms; and four pairs would suffice to determine distances at all points of the compass.

Atmospheric Electricity.—In a communication recently made to the Académie des Sciences M. Ch. André states that the presence of negative electricity during fine weather is a rare phenomenon, hitherto considered accidental, and for which a special cause foreign to the most generally received theories of atmospheric electricity has been sought. Exner attributes it to the presence of dust electrified by friction with the earth. Palmieri, on the other hand, thinks that he has found negative electricity to be invariably accompanied by a downpour of rain somewhere in the vicinity, the clouds being below the horizon. M. Ch. André then gives three instances taken from records at the Lyons observatory which do not fit with either theory. The dust hypothesis will not do, since no dust was observed, and the wind (south) which prevailed is at Lyons unfavourable to the carriage of dust. The rain hypothesis is also rejected, since on at least one of the occasions (July 10, 1889) none fell in the large region included between the sea and the Alps. M. Ch. André is of opinion that the temporary negative dip of the curve which took place about midday on June 24 and September 25 (1885), and July 10 (1889), must be attributed to the remarkable atmospheric conditions which obtained on these three days in the neighbourhood of Lyons, viz. (1) abnormal vertical distribution of temperature, such that on September 15th the minimum at the top of the Puy-de-Dôme was 9°C. higher than that at Clermont-Ferrand; (2), an exceedingly great relative dryness of the atmosphere on June 24th, the minimum of the hygrometer, which occurred about the middle of the negative dip, was the minimum for the June, July, August quarter for the eight years 1883 1891. The appearance of negative electricity in fine weather seems to M. Ch. André to be merely an exaggeration of the daily dip in the positive curve.

The Electrical Trade Section.—In the Annual Report of the London Chamber of Commerce it is stated that five meetings of this Section and its Committee have taken place during the year 1891. The question of Overhead Wires and the Model Clauses of 1889 and 1890, for the protection of telephones, received special attention in the early part of the year, and representations on both of these questions were made to the Board of Trade. The views of the Section in regard to the desirability of the commercial element being represented on the Electrical Standards Committee were also placed before the same Department. In August the Section had a conference with the Directors of the Crystal Palace, with a view to arriving at some agreement with the Company as to the advisability of postponing the opening of the Electrical Exhibition which that Company had projected. One beneficial result of the Conference was that the Crystal Palace Company agreed to postpone the opening of the Exhibition until the 1st of January. Under the auspices of the Section, a visit was made to the Frankfort Exhibition in the month of September. The most important action of the Section, says the Report, has been the drawing up of a memorial to the Board of Trade on the question of Overhead Wires. This memorial was signed by every leading electrical firm throughout the United Kingdom; and while the Board of Trade had already declared its fixed intention not to permit the erection of overhead wires under any circumstances, the object of the memorial was somewhat anticipated before it was sent in to the Board of Trade, by the Department declaring, in a letter to a private firm, (see *The Electrician*, January 8, p. 241), that it had never absolutely forbidden the erection of Overhead Wires, though it believed that their use was accompanied by many serious disadvantages. Probably the very representative character of the memorial, which the Board of Trade had been acquainted with through the medium of the electrical papers before the Chamber had had time to fully complete the list of signatories, had a very great deal to do with the considerably-modified decision which the Board of Trade gave on the subject while the memorial was in course of completion.

ELECTROMAGNETIC THEORY.—XXVII.

BY OLIVER HEAVISIDE.

(*Continued from page 537.*)

§ **130.** Returning to the theorem (147), or

$$\Sigma\, \mathrm{F}(\mathbf{N}) = \Sigma f, \quad . \quad . \quad . \quad . \quad . \quad . \quad (153)$$

let us take a few of the simplest cases that present themselves. Given any odd function F of **N**, the normal outwards from a closed surface over which the summation on the left side extends, we convert it to an equivalent summation throughout the enclosed region by making f, the quantity summed, be the value of $\Sigma\, \mathrm{F}(\mathbf{N})$ for the surface of the element of volume. This last is most conveniently a unit cube, so that

$$f = \nabla_1 \mathrm{F}(\mathbf{i}) + \nabla_2 \mathrm{F}(\mathbf{j}) + \nabla_3 \mathrm{F}(\mathbf{k}), \quad . \quad . \quad . \quad (154)$$

as in (148).

(*a*). The simplest case of all is $\mathrm{F}(\mathbf{N}) = \mathbf{N}$ itself. Then, by (154), or by considering that the vector normals to the six faces of a cube balance one another in pairs, we have

$$\Sigma\, \mathbf{N} = 0, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (155)$$

expressing that a closed surface has no resultant orientation; or, that a normal pull applied to every part of a closed surface, of uniform amount per unit area, has no resultant.

(*b*). If we multiply by p, any scalar function of position, we have the same case again if p be constant. When negative, it makes a well-known elementary hydrostatic result. But when p is not constant, then, by (154),

$$f = \nabla_1 \mathbf{i}p + \nabla_2 \mathbf{j}p + \nabla_3 \mathbf{k}p = \nabla p, \quad . \quad . \quad . \quad (156)$$

so that we have

$$\Sigma\, \mathbf{N}p = \Sigma\, \nabla p. \quad . \quad . \quad . \quad . \quad . \quad . \quad (157)$$

These are, of course, vector summations. The sum of the surface tractions equals the sum of the bodily forces ∇p arising from the space-variation of the internal tension. Take p negative to indicate pressure.

(*c*). Take $\mathrm{F}(\mathbf{N}) = \mathbf{ND}$, where **D** is a vector function of position. This gives the most valuable theorem of divergence,

$$\Sigma\, \mathbf{ND} = \Sigma\, \nabla\mathbf{D} = \Sigma\, \mathrm{div}\mathbf{D}, \quad . \quad . \quad . \quad (158)$$

already discussed.

(*d*). Take $\mathrm{F}(\mathbf{N}) = \mathbf{ND}\mathrm{P}$, where P is a scalar. Here, by (154), or by (158), we shall find

$$\Sigma\, \mathbf{ND}\mathrm{P} = \Sigma\, \nabla(\mathbf{D}\mathrm{P}). \quad . \quad . \quad . \quad . \quad . \quad (159)$$

Here ∇ has to differentiate both **D** and P, thus,

$$\nabla.\mathbf{D}\mathrm{P} = \nabla\mathbf{D}.\mathrm{P} + \mathbf{D}\nabla\mathrm{P}, \quad . \quad . \quad . \quad . \quad (160)$$

so that the previous equation may be written

$$\Sigma\, \mathbf{ND}\mathrm{P} = \Sigma\, \mathrm{P}\mathrm{div}\mathbf{D} + \Sigma\, \mathbf{D}\nabla\mathrm{P}, \quad . \quad . \quad . \quad (161)$$

which is a form of Green's Theorem relating to electrostatic energy. **D** may be the displacement in one system of electrification and P the potential in another. The quantity $-\Sigma\, \mathbf{D}\nabla\mathrm{P}$ is their mutual energy; and this is, by (161), equivalently expressed by the sum of products of every charge in one system into the potential due to the other.

(*e*). Take $\mathrm{F}(\mathbf{N}) = \mathrm{V}\mathbf{NH}$. Then, by (154),

$$f = \nabla_1 \mathrm{V}\mathbf{i}\mathbf{H} + \nabla_2 \mathrm{V}\mathbf{j}\mathbf{H} + \nabla_3 \mathrm{V}\mathbf{k}\mathbf{H}.$$

But here we may shift the ∇'s to the other side of the V's, because they are scalars; this produces

$$f = \mathrm{V}\nabla\mathbf{H},$$

so that we have

$$\Sigma\, \mathrm{V}\mathbf{NH} = \Sigma\, \mathrm{V}\nabla\mathbf{H} = \Sigma\, \mathrm{curl}\, \mathbf{H}. \quad . \quad . \quad . \quad (162)$$

The interpretation may be more readily perceived by reversing the direction of the normal. Take $\mathbf{N} = -\mathbf{n}$, so that **n** is the normal drawn inward from the boundary. Then

$$\Sigma\, \mathrm{curl}\, \mathbf{H} + \Sigma\, \mathrm{V}\mathbf{n}\mathbf{H} = 0. \quad . \quad . \quad . \quad . \quad (163)$$

If **H** be magnetic force, curl **H** is the electric current-density in the region. Now $\mathrm{V}\mathbf{n}\mathbf{H}$ is the surface equivalent of the bodily curl **H**. Ignore altogether the magnetic force outside the region, if there be any. Then the circuitation of **H** gives the current through a circuit. Applied to elementary circuits wholly within the region, the result is curl **H**. But at the boundary, where **H** suddenly ceases, there is a surface-current as well. To find its expression, apply the process of circuitation to a circuit consisting of two parallel lines of unit length, infinitely close together, but on opposite sides of the boundary, joined by infinitely short cross-pieces. Only the unit line inside the region contributes anything to the circuitation; and by taking it to coincide with **H**, so as to make the circuitation a maximum, we find that $\mathrm{V}\mathbf{n}\mathbf{H}$ represents the surface-density of current. So, if **J** be current, we have, by (163), $\Sigma\, \mathbf{J} = 0$ for any region, by itself. The surface-distribution and the volume-distribution of current are complementary; that is, they are properly joined together to make up a circuital distribution. Thus,

$$\mathbf{n}\mathrm{V}\nabla\mathbf{H} = -\nabla\mathrm{V}\mathbf{n}\mathbf{H}, \quad . \quad . \quad . \quad . \quad (164)$$

where on the left side we have the divergence (at the surface) of the internal current, and on the right the equal convergence of the surface-current.

§ **131.** Next, take a few examples of the extended Theorem of Version (152), viz.:—

$$\Sigma\, \mathrm{F}(\mathbf{T}) = \Sigma f, \quad . \quad . \quad . \quad . \quad . \quad (165)$$

where now, on the left side, we have the circuital summation of an odd function of **T**, and on the right an equivalent surface-summation, whose elementary part f is the value of $\mathrm{F}(\mathbf{T})$ for the circuit bounding the element of surface.

Taking three elements of surface to be unit squares, whose normals are **i**, **j**, **k**, we readily see that the corresponding f's are

$$\nabla_2 \mathrm{F}(\mathbf{k}) - \nabla_3 \mathrm{F}(\mathbf{j}), \quad \nabla_3 \mathrm{F}(\mathbf{i}) - \nabla_1 \mathrm{F}(\mathbf{k}), \quad \nabla_1 \mathrm{F}(\mathbf{j}) - \nabla_2 \mathrm{F}(\mathbf{i}). \quad (166)$$

By means of these we can see the special form assumed by f in any case.

(*a*). Thus, take $\mathrm{F}(\mathbf{T}) = \mathbf{T}$ itself, the unit tangent. Then we have

$$\Sigma\, \mathbf{T} = 0, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (167)$$

merely expressing the fundamental property of adding vectors, that the sum of any vectors forming, when put end to end, a circuit, is zero.

(*b*). Take $\mathrm{F}(\mathbf{T}) = \mathbf{T}\mathrm{P}$, where P is a scalar function of position. Then, with normal **i**, we have, by the first of (166),

$$f = \nabla_2 \mathbf{k}\mathrm{P} - \nabla_3 \mathbf{j}\mathrm{P} = \mathrm{V}\mathbf{i}\nabla.\mathrm{P}; \quad . \quad . \quad (168)$$

so, writing **N** for **i**, we obtain

$$\Sigma\, \mathbf{T}\mathrm{P} = \Sigma\, \mathrm{V}\mathbf{N}\nabla.\mathrm{P} = \Sigma\, \mathrm{V}\mathbf{N}\nabla\mathrm{P}. \quad . \quad . \quad . \quad (169)$$

The quantity summed over the surface is, therefore, the surface representative of the curl of $\nabla\mathrm{P}$. This has no volume representative, its value being then zero.

(*c*). Take $\mathrm{F}(\mathbf{T}) = \mathbf{TH}$. Here, with normal **i** to the element of surface, we have

$$f = \nabla_2 \mathbf{k}\mathbf{H} - \nabla_3 \mathbf{j}\mathbf{H} = \nabla_2 \mathrm{H}_3 - \nabla_3 \mathrm{H}_2 = \mathbf{i}\mathrm{V}\nabla\mathbf{H},$$

by (149). Therefore, putting **N** for **i**,

$$\Sigma\, \mathbf{TH} = \Sigma\, \mathbf{N}\mathrm{V}\nabla\mathbf{H} = \Sigma\, \mathbf{N}\, \mathrm{curl}\, \mathbf{H} \quad . \quad . \quad (170)$$

the Version Theorem again. But observe that, by the transformation (164), we may also write it

$$\Sigma\, \mathbf{TH} = \Sigma\, \mathbf{N}\mathrm{V}\nabla.\mathbf{H}, \quad . \quad . \quad . \quad . \quad (171)$$

similarly to (169), in which the operand is a scalar. This is mnemonically useful, but (170) is more practically useful.

(*d*). Take $\mathrm{F}(\mathbf{T}) = \mathrm{V}\mathbf{TH}$. Here, with normal **i**, the first of (166) gives

$$f = \nabla_2 \mathrm{V}\mathbf{k}\mathbf{H} - \nabla_3 \mathrm{V}\mathbf{j}\mathbf{H} = \mathrm{V}\,(\mathbf{k}\nabla_2 - \mathbf{j}\nabla_3)\mathbf{H}.$$

But here we have $\mathbf{k}\nabla_2 - \mathbf{j}\nabla_3 = \mathrm{V}\mathbf{i}\nabla$,

so that $f = \mathrm{V}\,(\mathrm{V}\mathbf{i}\nabla)\mathbf{H}$;

and therefore, generally, putting **N** for **i**,

$$\Sigma\, \mathrm{V}\mathbf{TH} = \Sigma\, \mathrm{V}\,(\mathrm{V}\mathbf{N}\nabla)\,\mathbf{H}. \quad . \quad . \quad . \quad (172)$$

(*e*). Let the quantity in the circuital summation be a vector of length P (a scalar function of position) drawn perpendi-

Digitized by Google

cularly to the plane of **T** and **N**. That is,

$$F(\mathbf{T}) = (V\mathbf{TN})P.$$

We then find, taking $\mathbf{N} = \mathbf{i}$, and using the first of (166),

$$f = \nabla_2 V\mathbf{ki} \,.\, P - \nabla_3 V\mathbf{ji} \,.\, P = (\mathbf{j}\nabla_2 + \mathbf{k}\nabla_3)P = \nabla P - \mathbf{i}\,(\mathbf{i}\nabla)\,P.$$

In general, therefore,

$$\Sigma\, V\mathbf{TN} \,.\, P = \Sigma\,(\nabla P - \mathbf{N} \,.\, \mathbf{N}\nabla P) = \Sigma\,\nabla_s P = \Sigma\, V\,(V\mathbf{N}\nabla)\mathbf{N}.P \quad . \quad (173)$$

The element of the surface-summation is $\nabla_s P$, meaning the slope of P on the surface itself, disregarding any variation it may have out of the surface. The last form of (173) involves the transformation formula (52).

Observe that in all the above examples,

$$\Sigma\, F(\mathbf{N}) = \Sigma\, F(\nabla), \quad . \quad . \quad . \quad . \quad . \quad . \quad (174)$$

when we pass from a closed surface to the enclosed region; and that

$$\Sigma\, F(\mathbf{T}) = \Sigma\, F(V\mathbf{N}\nabla), \quad . \quad . \quad . \quad . \quad (175)$$

when we pass from a circuit to the surface it bounds. Thus, **N** becomes ∇, and **T** becomes $V\mathbf{N}\nabla$. But I cannot recommend anyone to be satisfied with such condensed symbolism alone. It is much more instructive to go more into detail, as in the above examples, and see how the transformations occur, bearing in mind the elementary reasoning upon which the passage from one kind of summation to another is based (§§ 128, 129).

§ 132. The following examples relate principally to the modifications introduced by the differentiating functions of ∇.

(*a*). We have, by the parallelepipedal property,

$$\mathbf{N}V\nabla\mathbf{E} = \nabla V\mathbf{E}\mathbf{N} = \mathbf{E}V\mathbf{N}\nabla, \quad . \quad . \quad . \quad (176)$$

when ∇ is a common vector. The equalities remain true when ∇ is vex, provided we consistently employ the differentiating power in the three forms. Thus, the first form, expressing the **N** component of curl **E**, is not open to misconception. But in the second form, expressing the divergence of $V\mathbf{E}\mathbf{N}$, since **N** follows ∇, we must understand that **N** is supposed to remain constant. In the third form, again, the operand **E** precedes the differentiator. We must either, then, assume that ∇ acts backwards, or else, which is preferable, change the third form to $V\mathbf{N}\nabla.\mathbf{E}$, the scalar product of $V\mathbf{N}\nabla$ and **E**; or $(V\mathbf{N}\nabla)\,\mathbf{E}$, if that be plainer.

(*b*). Suppose, however, that both vectors in the vector product are variable. Thus, required the divergence of $V\mathbf{E}\mathbf{H}$, expanded vectorially. We have

$$\nabla V\mathbf{E}\mathbf{H} = \mathbf{E}V\mathbf{H}\nabla - \mathbf{H}V\nabla\mathbf{E}, \quad . \quad . \quad . \quad (177)$$

where the first form alone is entirely unambiguous. But we may use either of the others, provided the differentiating power of ∇ is made to act on both **E** and **H**. But if we keep to the plainer and more usual convention that the operand is to follow the operator, then the third form, in which **E** alone is differentiated, gives one part of the result, whilst the second form, or rather, its equivalent $-\mathbf{E}V\nabla\mathbf{H}$, wherein **H** alone is differentiated, gives the rest. So we have, complete, and without ambiguity,

$$\operatorname{div} V\mathbf{E}\mathbf{H} = \mathbf{H}\operatorname{curl}\mathbf{E} - \mathbf{E}\operatorname{curl}\mathbf{H}, \quad . \quad . \quad . \quad (178)$$

a very important transformation. It is concerned in the deduction of the equation of activity from the two circuital laws of electromagnetism.

(*c*). In these circuital laws we have also to consider the curl of a vector product, viz., the curl of the motional electric force in one law, and the curl of the motional magnetic force in the other. Taking the former, we have

$$\operatorname{curl} V\mathbf{q}\mathbf{B} = V\nabla V\mathbf{q}\mathbf{B}, \quad . \quad . \quad . \quad . \quad (179)$$

where **B** is the induction and **q** the velocity of the medium supporting it. Apply the elementary transformation (52) to (179). It gives

$$V\nabla V\mathbf{q}\mathbf{B} = \mathbf{q}.\nabla\mathbf{B} - \mathbf{B}\cdot\nabla\mathbf{q}, \quad . \quad . \quad . \quad (180)$$

when ∇ is a mere vector. But on the left side both **q** and **B** have to be differentiated; therefore the same is true in both terms on the right side. This gives

$$V\nabla V\mathbf{q}\mathbf{B} = \mathbf{q}\operatorname{div}\mathbf{B} + \mathbf{B}\nabla.\mathbf{q} - \mathbf{B}\operatorname{div}\mathbf{q} - \mathbf{q}\nabla.\mathbf{B}, \quad . \quad . \quad . \quad (181)$$

without ambiguity or need of reservation. That is to say, as in the $\mathbf{q}.\nabla\mathbf{B}$ of (180) both **q** and **B** have to be differentiated, we get $\mathbf{q}\operatorname{div}\mathbf{B}$ when **B** alone, and $\mathbf{B}\nabla.\mathbf{q}$ when **q** alone is differentiated. Similarly for the other term in (180).

Or we might write ∇_q when **q** alone, and ∇_B when **B** alone suffers differentiation. Then, fully,

$$V\nabla V\mathbf{q}\mathbf{B} = V\nabla_q V\mathbf{q}\mathbf{B} + V\nabla_B V\mathbf{q}\mathbf{B}, \quad . \quad . \quad (182)$$

$$V\nabla_q V\mathbf{q}\mathbf{B} = \mathbf{B}\nabla.\mathbf{q} - \mathbf{B}\operatorname{div}\mathbf{q}, \quad . \quad . \quad . \quad . \quad (183)$$

$$V\nabla_B V\mathbf{q}\mathbf{B} = \mathbf{q}\operatorname{div}\mathbf{B} - \mathbf{q}\nabla.\mathbf{B}. \quad . \quad . \quad . \quad . \quad (184)$$

Here the sum of (183) and (184) gives (181). The meaning of $\mathbf{B}\nabla$ and $\mathbf{q}\nabla$ has been already explained.

(*d*). Equation (181) may be applied to the circuital laws. Take the second, for example, in the form (4), § 66,

$$-\operatorname{curl}(\mathbf{E} - \mathbf{e}_0) = \mathbf{K} + \dot{\mathbf{B}} + \mathbf{w}\sigma - \operatorname{curl}\dot{\mathbf{B}}V\mathbf{q}\mathbf{B}, \quad . \quad (185)$$

and suppose that $\mathbf{w} = \mathbf{q}$, or that sources move with the medium. Then, by (181), we cancel the convective term $\mathbf{w}\sigma$. Further, we have $\dot{\mathbf{B}} + \mathbf{q}\nabla.\mathbf{B} = \delta\mathbf{B}/\delta t$, by (127), § 122, so that (185) becomes

$$-\operatorname{curl}(\mathbf{E} - \mathbf{e}_0) = \mathbf{K} + \delta\mathbf{B}/\delta t + \mathbf{B}\operatorname{div}\mathbf{q} - \mathbf{B}\nabla.\mathbf{q}, \quad . \quad (186)$$

and the corresponding form of the first law (equation (3), § 66), is

$$\operatorname{curl}(\mathbf{H} - \mathbf{h}_0) = \mathbf{C} + \delta\mathbf{D}/\delta t + \mathbf{D}\operatorname{div}\mathbf{q} - \mathbf{D}\nabla.\mathbf{q}. \quad . \quad (187)$$

The time-variations refer to the same (moving) portion of the medium now. But if we wish to indicate the movement of electrification, &c., through the medium, that is, have relative motion $\mathbf{u} - \mathbf{q}$ of ρ (and $\mathbf{w} - \mathbf{q}$ of σ) with respect to the ether, then to the right side of (187) add the term $(\mathbf{u} - \mathbf{q})\rho$, and to the right ride of (186) add $(\mathbf{w} - \mathbf{q})\sigma$.

It is desirable to preserve the velocities **u** and **w**, or else the relative velocities, as well as the velocity **q** of the medium, in order to facilitate the construction and comprehension of problems relating to electromagnetic waves, which, although abstract and far removed from practice, are of a sufficiently simple nature to enable one to follow the course of events.

(*e*). We have already had the divergence of the product of a scalar and vector under consideration. Now examine its curl. Thus,

$$\begin{aligned}\operatorname{curl}\mathbf{D}P &= V\nabla(\mathbf{D}P)\\ &= V\nabla\mathbf{D}.P - V\mathbf{D}\nabla.P\\ &= P\operatorname{curl}\mathbf{D} - V\mathbf{D}\nabla P. \quad . \quad . \quad . \quad (188)\end{aligned}$$

Here ∇ can only make a vector product with **D**, because P is scalar. On the other hand, both P and **D** suffer differentiation. So in the second line we have ∇ both before and after **D**.

(*f*). The divergence of the curl of any vector is zero. That is, $\operatorname{div}\operatorname{curl}\mathbf{H} = 0$, or $\nabla V\nabla\mathbf{H} = 0$. . . (189)

If ∇ here were a real vector (189) would mean that the volume of a parallelepiped vanishes when two edges coincide.

(*g*). A somewhat similar case is presented by the vanishing of the curl of a polar force. Thus,

$$\operatorname{curl}\nabla P = 0, \quad \text{or} \quad V\nabla\cdot\nabla P = 0. \quad . \quad . \quad . \quad (190)$$

Of course $V_{\nabla\nabla}$ is zero. But the scalar product $\nabla\nabla$, or ∇^2, is the Laplacean operator,

$$\nabla^2 = \nabla_1^2 + \nabla_2^2 + \nabla_3^2, \quad . \quad . \quad . \quad . \quad (191)$$

which occurs frequently.

(*h*). Let the operation curl be done twice on a vector. Thus,

$$\begin{aligned}(\operatorname{curl})^2\mathbf{A} &= V\nabla V\nabla\mathbf{A}\\ &= \nabla\cdot\nabla\mathbf{A} - \nabla^2\mathbf{A}, \quad . \quad . \quad . \quad (192)\end{aligned}$$

by the transforming formula (52). Or

$$\nabla^2\mathbf{A} = \nabla\operatorname{div}\mathbf{A} - \operatorname{curl}^2\mathbf{A}. \quad . \quad . \quad . \quad (193)$$

Thus there are two principal forms. If the vector **A** has no curl, then $\nabla^2\mathbf{A}$ is the slope of its divergence. If, on the other hand, it has no divergence, then ∇^2 has the same effect exactly as taking the curl twice.

In the case of the operand being a scalar, then we have

$$\nabla^2 P = \operatorname{div}\nabla P, \quad . \quad . \quad . \quad . \quad (194)$$

the divergence of the slope of the scalar.

(To be continued.)

ON THE HEAT PRODUCED BY EDDY CURRENTS IN AN IRON PLATE EXPOSED TO AN ALTERNATING MAGNETIC FIELD.

BY PROF. J. J. THOMSON, M.A., F.R.S.

In my paper "On the Discharge of Electricity through Exhausted Tubes without Electrodes" (*Phil. Mag.*, Nov., 1891, p. 459), I had occasion to investigate the absorption of energy by a piece of iron placed near a primary coil through which the rapidly alternating currents produced by the discharge of a Leyden jar were passing. In the following paper I apply this investigation to determine the rate of heat-production by eddy currents in the iron plates of an ordinary transformer, as I understand from Prof. Ewing that this question is, at present, of some interest to electrical engineers. The case I shall consider is that of an iron plate AB CD in a transformer, the plate being surrounded by wire through which an alternating current is passing.

We shall take as the plane of yz the plane parallel to the sides AB CD of the plate, and, midway between them, we shall suppose that the coils of wire are parallel to the axis of y, so that the magnetic force will be parallel to z. Let the magnetic force just outside the plate be $\mathbf{H}_0 \cos pt$. Inside the plate the magnetic force satisfies the differential equation,

$$\frac{d^2\mathbf{H}}{dx^2} = \frac{4\pi\mu}{\sigma}\frac{d\mathbf{H}}{dt} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where μ is the magnetic permeability of the plate and σ its specific resistance. Since $\mathbf{H}$ varies as the real part of ϵ^{ipt} where ϵ is the base of the Napierian logarithms, and $i = \sqrt{-1}$, equation (1) may be written

$$\frac{d^2\mathbf{H}}{dx^2} = \frac{4\pi\mu ip}{\sigma}\mathbf{H},$$
$$= m^2(1+i)^2\mathbf{H},$$

where $m^2 = 2\pi\mu p/\sigma$.

The solution of this equation is

$$\mathbf{H} = \{A\,\epsilon^{m(1+i)x} + B\,\epsilon^{-m(1+i)x}\}\,\epsilon^{ipt}.$$

Since the distribution of magnetic force is symmetrical with respect to the plane of yz we may write this equation in the form

$$\mathbf{H} = A'\{\epsilon^{mx}\cos(pt+mx) + \epsilon^{-mx}\cos(pt-mx)\}$$
$$+ B'\{\epsilon^{mx}\sin(pt+mx) + \epsilon^{-mx}\sin(pt-mx)\} \quad . \quad (2).$$

We can determine A' and B' from the condition that when $x=h$, where $2h$ is the thickness of the plate, $\mathbf{H} = \mathbf{H}_0\cos pt$.

Hence, putting $x=h$, and equating the coefficient of $\cos pt$ on the right-hand side of equation (2) to $\mathbf{H}_0$ and the coefficient of $\sin pt$ to zero, we have

$$\mathbf{H}_0 = A'(\epsilon^{mh}+\epsilon^{-mh})\cos mh + B'(\epsilon^{mh}-\epsilon^{-mh})\sin mh$$
$$0 = A'(\epsilon^{mh}-\epsilon^{-mh})\sin mh - B'(\epsilon^{mh}+\epsilon^{-mh})\cos mh.$$

Solving these equations we find

$$\left.\begin{aligned} A' &= \mathbf{H}_0\frac{(\epsilon^{mh}+\epsilon^{-mh})\cos mh}{\epsilon^{2mh}+\epsilon^{-2mh}+2\cos 2mh} \\ B' &= \mathbf{H}_0\frac{(\epsilon^{mh}-\epsilon^{-mh})\sin mh}{\epsilon^{2mh}+\epsilon^{-2mh}+2\cos 2mh} \end{aligned}\right\} \quad . \quad . \quad . \quad (3).$$

Substituting these values for A' and B' we find

$$\mathbf{H} = \mathbf{H}_0\left\{\frac{\epsilon^{2mx}+\epsilon^{-2mx}+2\cos 2mx}{\epsilon^{2mh}+\epsilon^{-2mh}+2\cos 2mh}\right\}^{\frac{1}{2}}\cos(pt+\epsilon)$$

Where

$$\tan\epsilon = \frac{\sinh m(h+x)\sin m(x-h) - \sinh m(h-x)\sin m(h+x)}{\cosh m(h+x)\cos m(x-h) + \cosh m(h-x)\cos m(x+h)}$$

where $\sinh\theta$ is written for $\frac{1}{2}(\epsilon^{\theta}-\epsilon^{-\theta})$, and $\cosh\theta$ for $\frac{1}{2}(\epsilon^{\theta}+\epsilon^{-\theta})$.

If v is the intensity of the current parallel to the axis of y, then

$$4\pi v = \frac{d\mathbf{H}}{dx}$$

$$= A'm\sqrt{2}\{\epsilon^{mx}\cos(mx+pt+\pi/4) - \epsilon^{-mx}\cos(pt-mx+\pi/4)\}$$
$$+ B'm\sqrt{2}\{\epsilon^{mx}\sin(mx+pt+\pi/4)$$
$$- \epsilon^{-mx}\sin(pt-mx+\pi/4)\} \quad . \quad (4)$$

The rate of heat-production per unit area of the plate is the mean value with respect to the time of

$$\int_{-h}^{+h}\sigma v^2 dx$$

Now the mean value with respect to the time of v^2 is by (4) equal to

$$\frac{m^2}{16\pi^2}(A'^2+B'^2)\{\epsilon^{2mx}+\epsilon^{-2m}-2\cos 2mx\}$$

Hence the mean value of

$$\int_{h}^{+h}\sigma v^2 dx = \frac{\sigma m}{16\pi^2}(A'^2+B'^2)\{\epsilon^{2mh}-\epsilon^{-2mh}-2\sin 2mh\}$$

Substituting the values we have previously given for A' and B', the rate of heat-production W is found to be equal to

$$\frac{\sigma m}{16\pi^2}\mathbf{H}_0^2\frac{\{\epsilon^{2mh}-\epsilon^{-2mh}-2\sin 2mh\}}{\epsilon^{2mh}+\epsilon^{-2mh}+2\cos 2mh} \quad . \quad . \quad (5)$$

For some purposes it is more convenient to express the rate of heat-production in terms of the average magnetic induction across the plate than in terms of the magnetic force outside the iron. If $\mathbf{B}$ is the maximum value of the mean induction across the plate, then since we have

$$\mathbf{B}\cos(pt+\alpha) = \frac{\mu}{2h}\int_{-h}^{+h}\mathbf{H}\,dx,$$

we find by substituting the value we have previously found for $\mathbf{H}$ that

$$\mathbf{B}^2 = \frac{\mu^2\mathbf{H}_0^2}{2h^2m^2}\frac{(\epsilon^{2mh}+\epsilon^{-2mh}-2\cos 2mh)}{\epsilon^{2mh}+\epsilon^{-2mh}+2\cos 2mh}.$$

Thus the rate of heat-production, expressed in terms of $\mathbf{B}$, is

$$\frac{h^2\sigma m^3\mathbf{B}^2}{8\pi^2\mu}\frac{(\epsilon^{2mh}-\epsilon^{-2mh}-2\sin 2mh)}{\epsilon^{2mh}+\epsilon^{-2mh}-2\cos 2mh} \quad . \quad . \quad (6).$$

When mh is very large we see from equation (3) that

$$A' = \mathbf{H}_0\epsilon^{-mh}\cos mh$$
$$B' = \mathbf{H}_0\epsilon^{-mh}\sin mh.$$

Hence, by (2),

$$\mathbf{H} = \mathbf{H}_0\{\epsilon^{-m(h-x)}\cos\{m(x-h)+pt\}$$
$$+ \epsilon^{-m(h+x)}\cos\{m(h+x)+pt\}\}.$$

Thus the magnetic force does not penetrate into the iron to a depth greater than a small multiple of $1/m$.

Let us now return to equation (5). We see that when mh is large, W the rate of heat-production is given by the equation

$$W = \frac{\sigma m}{16\pi^2}\mathbf{H}_0^2$$
$$= \sqrt{\frac{2\pi\mu p\sigma}{16\pi^2}}\mathbf{H}_0^2$$

In this case the work lost by eddy currents is independent of the thickness of the plate, which we can easily see must be the case, since the magnetic force and the currents are confined merely to a thin skin, and that by far the greater part of the iron of the plate is free from magnetic force and electric currents. When the plate is so thin that mh is small then equation (5) becomes

$$W = \frac{1}{3\pi^2}\mathbf{H}_0^2\sqrt{2\pi\mu p\sigma}\,m^3h^3$$
$$= \frac{1}{3\sigma}\mathbf{H}_0^2\mu^2p^2h^3.$$

Thus the heating effect in the plate increases as the cube of the thickness, the loss of energy from this cause is therefore greatly diminished when the thickness of the plate is diminished. If a slab of iron of given thickness is divided up into laminæ then, since the loss of energy in each lamina is proportional to h^3,

Digitized by Google

while the number of laminæ is proportional to $1/h$, the loss by heating in the whole slab will be proportional to h^2. In other words, when a slab of iron of given thickness is divided into thin laminæ the loss of energy by eddy currents is *inversely proportional to the square of the number of laminæ*.

The formulæ we have obtained show in a remarkable way when applied to the case of an ordinary transformer the importance of very fine lamination in the iron. Let us for example take the case of a transformer where the current makes 100 alternations per second. In this case $p = 2\pi \times 10^2$, for soft iron σ is about 10^4, and we shall suppose that $\mu = 500$, then $m = \sqrt{2\pi\mu p/\sigma} = 10\sqrt{2}$. The depth to which the magnetic force penetrates is comparable with $1/m$, in this case with $(1/10\sqrt{2})$ cm. or ·7mm. Thus in order to bring the whole of the iron into play the plate must not be more than 1·5mm. thick. The following table gives the loss of energy per second from eddy currents for plates of different thicknesses; the magnetic force outside the plate is supposed to be the same in all these cases, and the loss of energy in an infinitely thick plate is taken as unity.

Thickness of plate in millimetres.	Loss of energy per second due to eddy current.
Infinite	1
4	1
2	1·1
1	0·47
0·5	0·057
0·25	0·0075

Thus the loss of energy in a plate $\frac{1}{2}$ mm. thick is only about $\frac{1}{8}$ of the loss in a plate 1mm. thick. Thus, by building up a given thickness of iron in a transformer of plates 5mm. thick, the loss of energy will only be one quarter of what it would be if the plates were 1mm. thick. We see, too, that the lamination is of little use in checking the eddy currents if the plates are more than 1mm. thick. From the expression for w it follows that any increase in the rate of alternation of the current or the magnetic permeability of the iron demands a diminution in the thickness of the plates. I need not enter further into the practical consequences of these results, as I believe they are engaging the attention of Prof. Ewing.

NOTE ON THE USE OF THE ELECTRO-DYNAMOMETER.

BY WM. BREW.

The effect of neighbouring closed circuits upon an electro-dynamometer carrying an alternating current sometimes causes a considerable error in observation, and with some metal mounted instruments a deflection may be obtained by passing an alternating current through the swinging coil alone. The following method of investigating this effect, making, *pro tem.*, one of the stationary coils the disturbing influence, may be of interest:—

Close up the circuit of one of the stationary coils with a non-inductive resistance, r, equal to that of the swinging coil, and join up the other stationary coil in series with the swinging coil, then upon passing an alternating current of known strength, i_1, through these two coils, a secondary current, i_2, will be induced in the closed stationary coil, due to the mutual induction between the two stationary coils alone, if the effect due to any mutual or self-induction of the swinging coil be eliminated by taking the average of two readings with the swinging coil at equal angles on either side of its normal rectangular position. Note this average force reading F_1 upon the torsion head. Now pass the current i_1 through the stationary coil alone, and connect the swinging coil in series with the closed coil taking the place of the resistance r, and note again the average force reading F_2. Writing out the values of F_1 and F_2 we have:—

$$F_1 = i_1 G (g i_1^2 - g i_2^2) \cos\phi \quad . \quad . \quad . \quad (1)$$

$$F_2 = i_2 G (g i_1^2 - g i_2^2) \cos\phi \quad . \quad . \quad . \quad (2)$$

where ϕ is the angle of lag between the phase of the effective field due to the currents i_1 and i_2 in the stationary coils and the current in the swinging coils;

where G, g_1, g_2, are geometrical constants depending upon the coils.

From these two equations we see that

$$\frac{F_1}{F_2} = \frac{i_1}{i_2}, \quad \text{or,} \quad i_2 = i_1 \frac{F_2}{F_1} \quad . \quad . \quad . \quad . \quad (3)$$

The current i_2 in the closed coil thus becomes known irrespective of its difference in phase with i_1; i_2 might also have been due to a separate source of E.M.F. having the same period as i_1.

From the well-known relation—

$$\frac{i_1}{i_2} = \frac{\sqrt{R^2 + p^2 t^2}}{M p},$$

(where the right hand numerator represents the impedance of the closed circuit and the denominator the product of the coefficient of mutual induction M between the coils by 2π times the frequency). It will be seen that, having determined some of the constants of the coils we may adapt the instrument for a variety of purposes, such as the determination of an external impedance of low resistance in circuit with the closed coil, &c.

For general experimental work with the electro dynamometer, a dial of the following kind will be found a convenient adjunct. The graduation of the dial consists of two concentric circles, one of which indicates the square root of any deflection in any arbitrary measure, the only condition being that the number of divisions in the primary circle, from which the square-root circle is obtained, should be greater or less in accordance with the maximum current to be measured by the instrument, so as to keep the constant near unity. The other circle indicates at each point the logarithm of the square root of the deflection. Using the dial in the ordinary way, the logarithm corresponding to any deflection is read off the logarithm scale, and added to the logarithm of the constant. The pointer is then turned to the logarithm represented by this sum, and the number opposite to it is read off the square root scale which will be numerically equal to the current represented by the original deflection.

The dials of many zero ammeters containing iron show them to be practically electro dynamometers with variable constants due to the saturation of the iron in them as the current increases. The following experiment with two well-known types of ammeter, A and B—A containing a quantity of iron, B, on the other hand, possessing very little—may, perhaps, serve to illustrate one of the uses of the dial just described:—

A			B		
Current in amperes.	$\sqrt{\text{Deflection.}}$	Corresponding constant.	Current in amperes.	$\sqrt{\text{Deflection.}}$	Corresponding constant.
15·5	3	5·1	10·3	3	3·43
35·5	7	5·0	17·5	5	3·5
40·6	8	5·0	22·0	6	3·6
45·5	9	5·0	27·0	7	3·8
50·0	10	5·0	32·0	8	4·0
59·8	12	4·9	37·7	9	4·1
62·3	13	4·8	44·3	10	4·4
72·0	15	4·8	84·0	15	5·6
89·0	18	4·9	102·5	17	6·0

From the third column of the above table the slope of the magnetisation curve of the iron may be deduced, the variation of the instrument's self-induction, &c.

A potent factor which tends to make us keep the electro-dynamometer with its degree dial and constant, instead of converting it into a direct reading instrument, is the great saving of time accomplished in calibration by the *approximate* adjustment only of the spring to the range required (which is all that is necessary if a constant be used with the instrument), and the difficulty of obtaining a number of steel springs exactly the same as regards temper, &c. It is, of course, quite a straightforward job to adjust a spring approximately and graduate a dial to suit it, but this course would be very expen-

Digitized by Google

sive with every instrument, and a considerable saving is obtained by having 50 or 100 dials engraved at the same time to the same scale. But it is here the shoe pinches, for with every instrument the spring must be adjusted exactly to the dial. Steel springs seem to have answered best for this purpose according to most makers, probably on account of the weight of the moving parts and the considerable torsion required; but during many a struggle I have had with a steel spring I have heartily wished for the introduction of some other metal as a substitute, one similar to the alloys now being used so generally for smaller electrical measuring instruments. It will be seen that the dial described will adapt itself to the above circumstances, thus cheapening the cost of a direct reading instrument.

THE COMBINATIONS OF RESISTANCES.

BY MAJOR P. A. MACMAHON, R.A., F.R.S.

Resistances may be placed in circuit either in series or in parallel, or in various combinations of these methods. There are also networks such as the Wheatstone net, which are neither series nor parallel arrangements, and these are excluded from what follows. Every combination considered here consists of other combinations either in series or in parallel. Each must either consist of parallel combinations arranged in series, or of series combinations arranged in parallel. For the study of the subject it is convenient to make a few definitions. Two linear conductors may be placed either in series or in parallel. These arrangements may be defined as being conjugate the one of the other. It will be observed that the second of the arrangements merely differs in description from the first by the substitution of the word "parallel" for the word "series." To generalise the notion we may define two combinations to be conjugate when their descriptions merely differ by the interchange of the words "series" and "parallel."

A single linear conductor should, for the sake of unity, be regarded as being either in series or in parallel, and, further, as being a combination which is self conjugate. A combination consisting of parallel combinations in series will be called a series combination, and one consisting of series combinations in parallel a parallel combination. Thus, in the usual diagrammatic representation,

is a series combination, consisting of the three parallel forms

in series; and

is a parallel combination, consisting of the three series forms

in parallel.

The combinations into which series and parallel combinations are decomposable will be termed component parallel combinations and component series combinations respectively. The conjugate of any series combination is formed by placing the conjugates of the component parallel combinations in parallel. Similarly, the conjugate of any parallel combination is formed by placing the conjugates of the component series combinations in series. That this is so is evident, because by taking the conjugates of the component combinations, we merely interchange the words "series" and "parallel" in their descriptions.

The form  might be described by saying that two single forms are placed in parallel, and the combination then placed in series with two single forms. So also the form consists of two single forms placed in series, the combination being placed in parallel with two single forms. These two forms are thus conjugate, and may be said to constitute a conjugate pair.

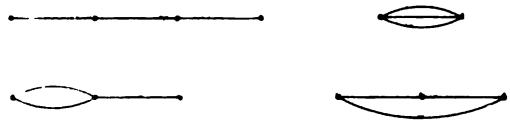
It may be gathered that all combinations naturally arrange themselves in conjugate pairs.

For one, two, three, four resistances, we have

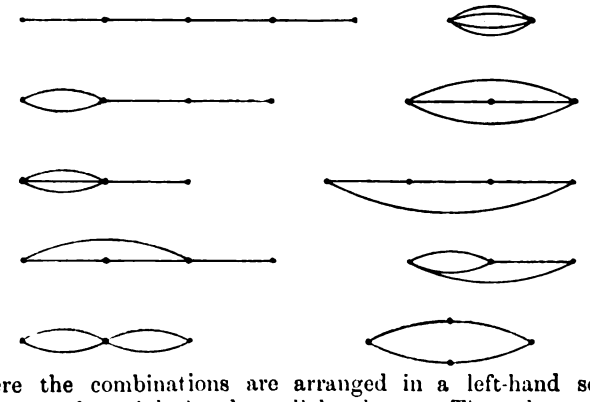
I.

II.

III.



IV.



where the combinations are arranged in a left-hand series column and a right-hand parallel column. The columns are conjugate, the one of the other. Conjugate pairs are found in successive horizontal rows.

In a similar manner the combinations of any number of resistances may be arranged in conjugate pairs.

It will be remarked that no attention is paid to the actual values of the resistances, but only to the *forms* in which they can be combined. The enumeration of the forms of combinations of a given number of resistances is of considerable interest. It can be shown that if $2A_n$ represents the number of combinations in the case of n resistances (n greater than one)

$$(1-x)^{-1}(1-x^2)^{-A_2}(1-x^3)^{-A_3}(1-x^4)^{-A_4}\ldots\ldots$$
$$= 1 + x + 2(A_2x^2 + A_3x^3 + A_4x^4 + \ldots\ldots\ldots$$

If the left-hand side of this identity be expanded by the binomial theorem, and comparison made with the right-hand side, the numbers in question are easily calculated. The results are

$2A_2$	$2A_3$	$2A_4$	$2A_5$	$2A_6$	$2A_7$	$2A_8$	$2A_9$	$2A_{10}$ .....
2	4	10	24	66	180	522	1532	4984.....

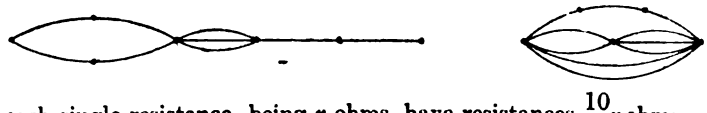
There is in regard to the combinations of equal resistances a very pretty and simple theorem which appears to have hitherto escaped notice.

If any number of resistances, each of r ohms, be combined so as to have a resistance of

$$\frac{p}{q}\ r \text{ ohms},$$

then the conjugate combination of resistances will have a resistance of $\frac{q}{p}\ r$ ohms.

In fact, conjugation merely inverts the fraction which presents itself as the multiplier of r. As an example, the conjugates,



each single resistance being r ohms, have resistances $\frac{10}{3}r$ ohms and $\frac{3}{10}\ r$ ohms respectively.

Digitized by Google

The inductive proof of the theorem is very simple. For suppose the law to hold in the case of two combinations whose resistances are

$$\frac{a}{b}\,r \text{ ohms and } \frac{c}{d}\,r \text{ ohms.}$$

The resistance obtained by placing these two combinations in series is

$$\left(\frac{a}{b}+\frac{c}{d}\right) r \text{ ohms.}$$

The conjugate of this new combination is obtained by placing the conjugates of the component combinations in parallel, and since the law is assumed to hold for the component combinations, the resistance obtained will be

$$\frac{\frac{b}{a}\cdot\frac{d}{c}}{\frac{b}{a}+\frac{d}{c}}\,r \text{ ohms,}$$

which is

$$\frac{1}{\frac{a}{b}+\frac{c}{d}}\,r \text{ ohms.}$$

This proves that the law holds for the new combination.

Similarly assuming the law to hold in the case of two combinations of resistance, $\frac{a}{b}\,r$ ohms and $\frac{c}{d}\,r$ ohms, we obtain, by placing them in parallel, a new resistance

$$\frac{\frac{a}{b}\cdot\frac{c}{d}}{\frac{a}{b}+\frac{c}{d}}\,r \text{ ohms.}$$

And, moreover, the resistance obtained by placing their conjugates in series is

$$\left(\frac{b}{a}+\frac{d}{c}\right) r \text{ ohms,}$$

and

$$\frac{b}{a}+\frac{d}{c}=\frac{1}{\frac{\frac{a}{b}\cdot\frac{c}{d}}{\frac{a}{b}+\frac{c}{d}}}.$$

Hence, since every combination is decomposable into two combinations, either in series or in parallel, and the law is obviously true for the simpler cases, it must hold universally.

According to the definition here made of the word "conjugate," it will be remarked that capacities of condensers combine according to the law of the conjugate combinations of resistances.

DIELECTRIC HYSTERESIS.*

BY CHAS. STEINMETZ.

In a Paper read before the American Institute of Electrical Engineers on January 19, 1892 (see *The Electrician*, February 12, *et seq.*), I have proved by experimental data, that the loss of energy in iron and other magnetisable bodies, under alternating magnetic strain, is expressed by the formula,

$$H=\mu B^{1.6},$$

that is, proportional to the $\frac{1}{6}$th power of the intensity of the magnetic field.

The analogy existing between the behaviour of dielectric bodies in an electrostatic field with that of a magnetic body in a magnetic field suggested that in dielectric media in an electrostatic field, for instance in the insulating medium of a condenser which is alternately charged and discharged, a consumption of energy takes place, which depends upon the intensity of the electrostatic field according to a law similar to that of magnetic hysteresis.

That in the dielectric medium of a condenser, which is connected with an alternating E.M.F., a consumption of energy takes place, is known from the fact that the condenser gets hot, while it does not get hot when connected to a source of equal, but constant potential.

To determine this loss of energy and its dependence upon the E.M.F., I made towards the end of January, 1892, a number of tests with a condenser of three microfarads capacity, with paraffin paper as insulating medium, by connecting this condenser in an alternating-current circuit of 170 complete periods per second, and measuring the energy consumed by the condenser in a similar manner, and with the same apparatus that was employed in the tests on magnetic hysteresis.

After subtracting the energy consumed by the leakage current—which was found by testing with a continuous current of equal E.M.F.,—and the energy consumed by the instruments, it was found that :—

The energy consumed by the dielectric medium under alternating electrostatic strain is directly proportional to the square of the intensity of the electrostatic strain; that is, proportional to the square of the E.M.F. acting upon the condenser; or, expressed in symbols,

$$H=k\,E^2.$$

Hence, while the magnetic hysteresis follows the law of the $\frac{1}{6}$th power, the dielectric hysteresis follows a simple law of squares—that is, it acts just the same as a mere dead resistance connected into the circuit.

The tests covered the range from 80 volts up to 320 volts, and agreed very nicely with the law of the square. Beyond 320 volts the dielectric medium apparently began to give way, and the energy-consumption increased faster than proportional to the square of the E.M.F. That was still more marked in a second set of observations, made right after the condenser was overstrained. Here the deviation from the law of squares began even at a lower E.M.F., and the energy-consumption increased so rapidly with increasing E.M.F. that the tests had to be interrupted. In a third set of tests, on the next day, the dielectric had somewhat recovered; the energy-consumption remained proportional to the square of the E.M.F. up to about 250 volts, then increased more rapidly, and then suddenly increased very much, while the E.M.F. went down, and a hissing noise was heard in the condenser; it had given way.

From the above we derive the conclusion, that up to an E.M.F. at which the dielectric begins to break down the energy-consumption in the dielectric of a condenser is proportional to the square of the E.M.F. acting thereupon.

THE RIES REGULATING SOCKET.*

This device for enabling a glow lamp to be "turned down" like a gas burner, consists of a small choking coil mounted in a lamp holder. The accompanying illustrations explain the construction of the socket. Fig. 1 is a sectional elevation, Fig. 2 a side elevation with part of enclosing shell broken away, and Fig. 3 a diagram view showing the coil and circuit connections. As will be seen, the socket comprises a finely laminated iron ring A, wrapped at one operation with a cable, B, composed of a number of well-insulated

copper wires, the ends of which are brought to a row of contact pins, C, arranged in the path of an arm, D, connected to the operating key, in such a manner that all of the wires of the cable are, by means of these pins, connected in series with each other and with the lamp. The coil thus formed is mounted upon an insulating block H, contained within the enclosing shell, to which block are likewise secured the lamp-holding contacts, the operating key and the binding screws L M to which the leading-in wires are attached.

The amount of counter E.M.F. generated by this socket varies according to the position of the operating key and its arm. The coil is so arranged that when the arm D is removed from its open-circuit position at the extreme right and rests upon contact No. 7, Fig. 3, all of the winding B is in circuit with the lamp. In this position the counter E.M.F. generated by the coil is greatest, so that only a small portion of the applied voltage, sufficient to just render the lamp filament visible in the dark, is permitted to pass to the lamp. As the arm D is moved toward the left over the series of contact pins C, it cuts out successive sections of the winding B, thereby reducing the length of wire subjected to the inductive action of the core A, and correspondingly increasing the amount of light given by the lamp, until when the arm finally rests upon contact No. 1, all of the coil sections are cut out, and the lamp burns at its greatest brilliancy.

The following test of the Ries socket for varying the candle-power of lamps supplied with alternating currents, was made by Mr. Henry Stott with a view of determining the efficiency of the device. The socket tested was marked "50 volts, 25 c.p.," but as no 25 c.p. lamps were at hand a 16 c.p. was used, and from the fact that, when the switch was on the last step, putting all the coils in circuit, the filament only gave a dull red glow of about a quarter of a candle, it seemed quite well suited to this lamp.

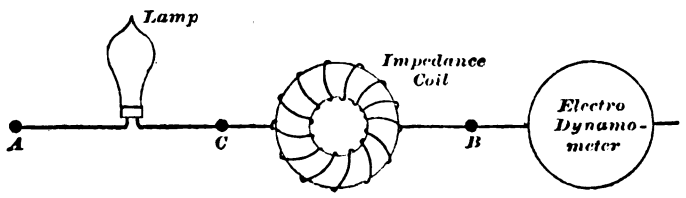

FIG. 4.

The method of carrying out the test was one described by Messrs. Ayrton and Sumpner, with a slight modification to suit the case, the rationale of which is briefly as follows, referring to the accompanying diagram (Fig. 4) :—

Let V_1 = Difference of potential between points A and B.
" V_2 = " " " " " A and C.
" V_3 = " " " " " B and C.
" r = Resistance of lamp.

The watts expended in coil $= \frac{V_1^2 - V_2^2 - V_3^2}{2r}$.

As the resistance of the lamp was a variable, an ammeter on the dynamometer principle was inserted, and the value $\frac{V_2}{a}$ substituted for r, a being the current measured in amperes.

The formula then becomes

$$W = \frac{V_1^2 - V_2^2 - V_3^2}{2\frac{V_2}{a}} = a\frac{(V_1^2 - V_2^2 - V_3^2)}{2V_2}.$$

All readings were taken simultaneously, the volts being read on the Weston type of voltmeter by simply releasing the spring, which stops the motion of the needle, at the same moment that the ammeter was read, and the reading noted before again releasing the needle. The ohmic resistance of the coils was determined immediately after the test by the ordinary bridge method. The paradox of the sum of two E.M.F.'s being greater than the E.M.F. supplied is well illustrated in the table given, as in one case it exceeds the E.M.F. on the mains by 13·5 volts. The accompanying table gives the results of the test, and shows the efficiency of the socket at various degrees of incandescence of the lamp.

ON THE THEORY OF THE AUTOMATIC CONTACT-BREAKER.*

BY V. DVORÁK.

The author points out that in the original theory of the spring cut-out (the inaccuracy of which was indicated by Koppe) the effect of the electro-magnet on the keeper, during the return to the original position, is entirely overlooked, and its attraction is only considered when the keeper is in the position of rest. Since the effects of the actual attractions referred to must be equal and opposite, they can contribute nothing towards the maintenance of the vibrations, supposing that we neglect other important circumstances. The other ways in which the vibrations of the hammer can be affected will now be investigated. They include the retardation of contact, self-induction, the influence of the iron, the dimensions of the core and hysteresis. A complete theory of Wagner's hammer can then be constructed. The curve formed by the increasing current on making contact can be represented by two incomplete sine curves differing by T/4 in phase. The first represents the force which is proportional to the distance from the position of equilibrium, and is in operation only during the movement of the keeper from this position up to the magnet and back again, that is during half a vibration. It can have no influence on the maintenance of the vibration which is kept up by the second curve differing in phase by T/4. It is this, therefore, that has to be attended to in the winding in order to make the amplitude of the vibration as great as possible. With a specially constructed Wagner-Elsa's hammer, which depended on the torsional vibration of an elastic wire, an approximate determination of the energy necessary to maintain the vibrations was arrived at. The result proved that such a hammer must be regarded as an extremely inefficient motor, as approximately only about 1 per cent. of the energy was applied in maintaining the vibrations.

The most important conclusions are as follows:—Owing to the small amount of energy requisite for maintaining the vibrations, the resistance of the cells must be kept quite low. Also the resistance of the magnets must not be too great, as this does not conduce to reliability and powerful action of the bell. As to whether the design could be best improved by the use of a shunt or an extra current circuit (in large bells) or a closed secondary coil, the author does not decide. If the circuit breaker is to be made specially powerful (*e.g.*, for acoustic purposes), the former means can be used with advantage; in particular, the ratio of the coefficient of self-induction to the total resistance must be given a suitable value, and this must be considered in determining the number of ampere turns.

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*" *All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.		6 months.		12 months.	
	s.	d.	s.	d.	s.	d.
For the United Kingdom	5	0	10	0	19	6
For Foreign Parts and Colonies:—						
Within Postal Union	6	6	12	6	24	0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7	6	14	6	28	0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

GOOD FRIDAY WEEK.

"THE ELECTRICIAN" will be published on THURSDAY in Good Friday week, instead of Friday.

Contributors' and Advertisers' copy must reach the Office by Wednesday at latest.

THE COMPOUND WINDING CASE.

Although of comparatively trifling importance so far as the royalties were concerned, the compound winding patent, which has at last been finally upset in the House of Lords, removes one more of those burdens which the patent system allows to harass, if not to impede, the industries of this country. These burdens are fortunately so few that they do not even in the aggregate constitute a serious objection to the patent system, but for various reasons they are peculiarly vexatious. In this particular instance, the Brush Corporation acquired, among numerous other patents, one which described the addition of a "teazer" or shunt winding, which was to overcome the difficulty in series-wound machines, since in these "as ordinarily constructed, no magnetic field," says the specification, "is maintained when the external circuit is open, except that due to residual magnetism." The dynamo described in this patent was for electro-plating, and it was suggested that this construction would enable it to do a large quantity of work at one time and a small quantity at another time. The inventor had not the slightest idea about running glow lamps, which were hardly thought of, or about distribution at constant potential, which LANE FOX had not yet propounded, and the Directors of the Brush Corporation had no notion of the fact that among their patents there was one which might turn out to be of such unexpected value. After careful disclaimers in 1882 and 1886, the Brush Corporation, who were merely making the most of their property, began to demand royalties. The demand was felt to be vexatious, because everybody knew that the first real compound-wound dynamo

Digitized by Google

was built by Mr. Crompton, to the designs, we believe, or under the superintendence of Mr. Swinburne.

We have described the earlier part of the fight on a former occasion, and need only remind our readers that it was found by a small association of dynamo makers, who began to prepare a case, that it would be cheaper to pay the royalty of 10s. per unit, adding the amount, of course, to their price lists. The Chairman of the Brush Corporation had no right whatever to say, in 1889, that the controlling patent for compound winding had been admitted by the English makers. Messrs. King, Brown and Co. took a more high-spirited view; and, while declining to pay what they considered to be an unjust tax, have squandered more money on the legal profession than would have paid their royalties a dozen times over. We cannot but grudge that so much money should have been lost to the electrical trade. This enterprising Scotch firm are to be congratulated on freeing the whole industry from the payment of a royalty which would have been viewed in a very different light if it had really been asked for a genuine invention, either made by one of the staff of the Corporation or openly bought, like many other patents, for their apparent purpose. It is this manipulation of the meaning and twisting of the text, and putting into a patent that which the inventor never dreamed of, that encourages "fishing" patents. There are one or two patents still hanging over the electrical trade—the Hopkinson three-wire system, and the Edison feeder system. The lamp-holder and double-carbon arc lamp patents are no longer to be feared; but if multiphase motors come into general use there will probably be some attempt to set up a general claim.

Previous to the Act of 1883 it was optional with the patentee whether he would grant licences authorising other persons to use his invention; but now, if any person petitioning the Board of Trade proves that the patent is not being worked in the United Kingdom, or that the reasonable requirements of the public cannot be supplied, or that any person is prevented from working or using to the best advantage an invention of which he is possessed, the Board of Trade may compel the patentee to grant licences, and may order the amount of royalties, security for payment, &c., as, having regard to the nature of the invention and the circumstances of the case, they may deem just. This may some day be used to prevent a selfish or oppressive use of the monopoly granted by the patent system, but such compulsory licences have never, so far as we are aware, been applied for; perhaps because no invention of sufficient importance has been made since 1883, or, if made, has not been the occasion of exorbitant demand. Whatever may be said against the compound-winding patent of Brush, it must be admitted that the Brush Corporation did not set their claims too high. They did not wait for years and spring an unknown patent on an unsuspecting trade; the royalty was substantial, but could without serious difficulty be recovered from the purchasers of dynamos. It was not sufficient to place the manufactures of the Corporation at any material advantage compared with those of competing manufacturers.

If we are not mistaken, we shall in the future see less of these general and wide-spreading patents applied for by men who, like Brush, Lane Fox, and Edison, dimly saw that they had hit on something. They felt that at that time the air was full of new discoveries, and that every idea should be seized on and secured. Ideas are not more scarce now, on the contrary, they are overwhelming; but we know more clearly what we are working at. A distinct invention for a new contrivance intended for and actually used for a particular object or purpose, or a combination of new or old parts for a definite result, appeals at once to common sense and justice. It is when the invention is used for another purpose, or when the result is arrived at by slightly modified parts, that difficulties begin. Definiteness of aim and clearness of specification are more common to-day than they were twelve years ago; and we hope that twelve years hence these expensive lawsuits will be rare, or, if disputes must arise, that they may be settled in some less costly manner.

OBITUARY.

CHARLES J. VAN DEPOELE.

We regret to have to record the death of Mr. Charles J. Van Depoele, at Lynn (Mass.), on March 18th.

Mr. Van Depoele, who was in his forty-sixth year, was a Belgian by birth. In 1864 his family removed to Lille, France, and in a short time the young man attracted the attention of Dr. Patoir through his electrical experiments and exhibitions of electrical apparatus. In 1869 Mr. Van Depoele went to Detroit, Michigan, where he continued his experiments. Many different styles of lamps were made and experimented with, and not less than fifteen different styles of dynamos were made and tested, with all sorts of combinations and winding. The studies and experiments were continued vigorously, and every now and then Mr. Van Depoele gave an exhibition of the electric light to the public. In 1879 he lighted up Adam Forepaugh's circus; a few days later the Detroit Recreation Park, the Detroit Grand Opera House, &c. These exhibitions attracted the attention of capitalists, who cheerfully offered their assistance, and the experimenting shops were transferred to the Detroit Novelty Works in Hamtramck, where several new machines were built and experiments continued until 1880, when a company was formed to enter upon the manufacture of electric light machinery. Finding, however, that Detroit was not the real field, the Company was transferred to Chicago, where a new Company was formed, under the name of Van Depoele Electric Manufacturing Company. This Company experimented in electric railway work, and in 1887 had 13 electric railways in successful operation, the first one being at South Bend (Ind.), which was equipped in 1885. In March, 1888, the Van Depoele Electric Manufacturing Company sold their electric railway business to the Thomson-Houston Company, Mr. Van Depoele being engaged as inventor and electrician to the Company, which position he occupied up to the time of his death.

REVIEWS.

The Electric Railway in Theory and Practice. By Oscar T. Crosby and Louis Bell, Ph.D. New York: The W. J. Johnstone Company. London: "The Electrician" Printing and Publishing Company.

The task undertaken by the authors of this book is comprehensive, including, as it does, the historical, commercial, theoretical, and practical aspects of the electric railway; but, as stated in the preface, no attempt is made to give a detailed study. The subject is divided into twelve convenient chapters in a clear and definite manner, so that there is little difficulty in finding the information contained. Special points of practical import are further elucidated in five appendices.

The first chapter refers to the theory of electrical machines, and calls for no special comment other than that the views are clearly expressed in rough general terms, which will appeal to railroad engineers. Exception may be taken to some of the Americanisms; but the use of "electrics" on page 16 seems very happy. On page 22 the length of the keeper—yoke, as we should say—is given as 36in.; it would appear from the context to be 34in. Expressing the armature magnetic density in C.-G.-S. lines per square inch is open to question, though Prof. Silvanus Thompson has used the same mixed units in his class lectures.

In Chapter II. prime motors are discussed, and the relative advantages of small high-speed simple engines and large compound Corliss engines are considered. The importance of taking frequent diagrams, so as to set the valves at the most efficient point of cut-off, and the necessity for extra heavy fly-wheels with considerable inertia, in order to overcome the rapid variations of power required on small lines, are strongly insisted on. The particular field for turbine or water wheels is also pointed out.

Perhaps the most interesting chapter is that referring to the motor and car equipment. The problem before the motor designer is clearly stated, and the various approximations found most expedient in practice are detailed at length. The two methods of securing a fairly uniform speed by changes in the field excitation or by interpolated resistance are illustrated by numerical examples, and it is shown that experience tends towards a combination of the two. This practice is quite in accord with English and Continental methods, and points to a state of finality in arrangement, if not in detail. Judging from the long list of general instructions given to car drivers, it would appear that a regulation by the field changes only, as formerly practised by the Sprague Company, was productive of no little trouble. For instance, on page 122 occurs the following passage:—"When necessary to go beyond the fourth notch, pass slowly to the seventh, never stopping on the fifth or sixth; and always use the seventh notch on grades." There is, of course, nothing exceptionally difficult in the above instruction; but, judging from English experience, such a complicated arrangement would lead to many "burnt-out" field windings. Perhaps, however, the American driver is more sober than the average tram hand here. It is no wonder, however, that the Edison General Electric Company have lowered the combined field-coils resistance from about 20 to 8·6 ohms, and have put 6 ohms in series with the motor for starting. We note that the Thomson-Houston Company wind the field in two coils, which are coupled in series with each other, and also with an external resistance. After the latter is cut out of circuit one-half of the field wire is cut out as well.

The vexed question of single *versus* double motors is well handled. It is pointed out that in the early days when motors were not so reliable as now, two motors in parallel were a great safeguard; but that now accidents from this cause are so reduced in number that the proper reserve for each car is the car immediately following, which can always push it to the journey's end or the depôt. The efficiency of one large motor and one set of gearing is, say the authors, about 10 per cent. greater than that obtainable with two small motors giving the same tractive effect. Double motors seem to have for their especial field lines serving between residential country districts and cities; then the motors are coupled in parallel outside the city boundary, and run in series within the area where a high speed is not permissible. On pages 81 and 82 the methods of coupling motors in parallel are discussed, and the errors resulting are shown. Varying-ratio gearing is naturally mentioned, but no practical solution of the speed-varying problem is given, though hopes of success in this direction are hinted at. Such a gearing would put railway work on a much better footing. The general methods of gearing motors to axles are detailed at some length, but it is pointed out that straight-cut steel gear seems to give the best all-round results. Raw hide is unreliable, and morticed wheels are difficult to make with the small pitches required. Single and double reduction motors are also compared. Taken all round, it appears that a net gain of at least 5 per cent. efficiency is obtained by the single reduction, and decidedly the wear and tear of gearing is less. But the motor is larger, and, consequently more costly, and has, *per se*, a lower all-round efficiency, particularly if the service demand frequent stops. It is, perhaps, too soon to predict whether the gearless motor will supplant the single reduction. But on high-speed lines with long runs it is likely to do so if the armatures will stand the strain. The Short gearless motor has the armature carried in a separate sleeve with spring attachments; the Westinghouse armature (drum type) is boldly keyed on the rolling axle. The authors point out that the character of the road and service must largely affect the success of these motors, and only time can settle the superiority of one or the other—most likely they each have their particular field of operation in which they are *facile princeps*—the ultimate test is small coal consumption and freedom from breakdowns. The typical American motors are illustrated, and also the general types of motor-trucks. The bogie-trucks for long cars are interesting. On pages 102-104, rough data for estimating the power absorbed by cars under different circumstances are given, and on page 105 the various means of getting sufficient adhesion for stiff grades are detailed.

The trolley receives the attention it deserves, and the principle is clearly evolved. Diagrams of standard car wirings are published, we believe, for the first time. It may seem curious to the untravelled English engineer that cars should be heated as well as lighted by electricity; but although the cost is as high as 72 cents per day, against 10 cents with stoves, yet the greater convenience makes the additional cost permissible. A section of Chapter III. is given to lightning-arresters, and is well worth careful reading (see also Appendix E.). The "line" is discussed in Chapter IV., both mathematically and practically. The most interesting section in it, perhaps, is that relating to the "return" or earth circuit, and the interference with telephones. In Appendix A. are stated two opinions given respectively by the Superior Court of Cincinnati and the Supreme Court in the State of Ohio. It appears at present that the double trolley system will not be insisted on, and that the telephone companies will have to use an insulated metal return, which will vastly improve the communication.

Next the "track" is referred to in Chapter V., and English engineers will be surprised at the variety and curious shapes of the American rails. Generally these appear to be lighter than those used here. On p. 149 the desiderata for a really efficient tram track are mentioned in forcible language by Mr. F. H. Monks. Undoubtedly the sooner tramway companies realise that a well-laid road means less wear and tear of plant, as well as smaller coal consumption, the better. The car house, snow ploughs and sweepers are also illustrated and described.

Chapter VI. is devoted to the station, and the various considerations affecting the choice of position are well set out. The large variation of power (as much as from zero to 150 H.P. and back again to zero in a single minute, being shown in one load diagram on page 164) and the necessity of the strongest and best material in engine and dynamo are insisted upon—these being the more urgent with small lines and heavy grades. On page 171 we find a table of power required at the wheels, with a 16ft. normal car, weighing about five tons empty, for grades varying between 0 per cent. and 5 per cent. The *average* power and the *maximum* power are then discussed in relation to the size of engine and dynamo. Lines of various capacities are enumerated, and the proper size of electric and steam "unit" approximated, examples from practice being given. This chapter is worth very careful perusal, containing, as it does, hints gathered from a large practical experience.

The efficiency of electric traction is treated in a separate chapter, which is by no means the least instructive part of the book. The authors show that the main losses occur in the engine plant, the motor gearing and regulating devices; the efficiency of the dynamo, line, and motor being fairly high, and leaving, in the nature of things, little room for improvement. It is impossible in a review to do more than refer generally to the points at issue. Experience shows that the average power required per 16ft. car with two 15 H.P. motors, is about 6 to 8 E.H.P., and in few roads does it exceed 10 E.H.P. under normal conditions. The authors state that the dynamos should have a rated capacity of half the aggregate rated capacity of the motors. But the engine-rated capacity (I.H.P.) should not be more than about 75 per cent. of that of the dynamos. By these proportions the engines will be worked on the average near their points of maximum efficiency. The dynamo efficiency, of course, varies little between half and full load. Such a plant will have a small coal consumption and yet will meet the varying demands of power promptly and without undue strain to either engines or dynamos. Line and conduit difficulties, motor efficiency and gearing, are also discussed under this

Digitized by Google

head. The authors find the average commercial efficiency from car wheel to engine to be about 40 per cent. with present practice, and look to a possible average efficiency of from 50 to 60 per cent. in the future on large and well planned lines. The coal consumption may be gathered from data given to vary between 5lb. and 7lb. per car mile.

The question of storage battery traction is introduced and characterised by the following drastic description :—"Manners none; customs beastly." This sweeping criticism is, perhaps, hardly justified in view of recent improvements made in traction accumulators both in Europe and America. But after thus showing their own predilections the authors settle down to a pretty fair discussion of the position of the self-contained car, at any rate so far as America is concerned. The battle really turns on whether the overhead or the conduit system be permissible; if neither be so, then the accumulator or the horse car has the field, and it is really a simple question of cost between the two systems. The authors very rightly point out that it is by no means certain that any type of accumulator in the market to-day will necessarily share in the ultimate success of this form of traction.

Chapter IX. deals with conduit, third rail, and constant-current systems, and even telpherage is not forgotten. The authors then give a chapter to "high speed service," and discuss at length the pros and cons of obtaining a rate of 150 miles per hour by means of electric motors. The subject is well handled and carefully treated; but, the authors remark, it is not easy to-day to make even an "educated guess" as to the limiting speed of either steam or electricity. Probably the commercial aspect is the more important for the present. It certainly seems probable that if the demand were made the engineers would meet it. High-speed resistances are known to be much less than supposed by our leading authorities of 20 years ago or more. This chapter very fitly concludes with the favourable though guarded report of Prof. Henry A. Rowland and Dr. Louis Duncan on Mr. Crosby's figures.

Commercial considerations are discussed in Chapter XI. This should form very instructive reading for tramway managers and engineers. Although the figures are based on American experience, there will be little difficulty in converting most of them to the prevailing rates of any given district. On page 323 is a so-called "curve of coefficient of rides per capita in cities of the United States." The ordinates are "rides per capita per annum," and the abscissæ are the population of cities measured by thousands. The authors state that experience shows that at the present rates of fare—almost everywhere 5 cents—each car, running an average of 110 miles per day, must carry from 330 to 440 passengers per day "to live." It thus follows that the possible number of paying cars can be readily told by inspection of the curve. Following next comes a table giving the "Street Railway Statistics for 50 Cities." It will be noticed that the number of cars reported is always in excess of the number of "cars possible to be supported," as determined by the previously mentioned table; but a foot note draws attention to the fact that many of the cars are old, obsolete, or in reserve. From the above it would appear that an American line requires to earn from 30s. to 40s. per day per car in order to pay its way. These limiting figures will form no guide to English practice, since the conditions of running are altogether different.

The curious increase of traffic on lines converted from horse to electric systems is strongly supported by figures. The authors state that the increase in gross receipts varies from 25 per cent. to 300 per cent., and is rarely less than 30 per cent., even when the previous horse service has been good. These facts speak for themselves, and stand in strong judgment on the policy pursued in this country.

The historical notes are of no particular interest, being chiefly a summary of what we already know. Appendix B. contains clear and minute instructions for wiremen. Appendix C. gives a convenient form of log-book for use by an engineer in charge of a station. Appendix D., compiled by H. L. Bettis, gives a "classification" of expenditures for electric railways. It seems to be based on the Thomson-Houston method of conducting business. Appendix E. is written by Prof. Elihu Thomson, and refers to lightning protection. The subject is clearly treated, and sound practical advice for the safe guarding of station, dynamo and motors is offered.

Broadly reviewed, "The Electric Railway in Theory and Practice" is a well-written compendious text-book. Perhaps the fault most apparent is inherent in the subject, *i.e.*, the mass of information extant is so voluminous that it is impossible to cram into the 400 pages the whole of even the more important matter. So that some readers will miss what they most want, or find it insufficiently dealt with. In a future edition the historical section might with advantage be omitted, and the utility of the book would be largely increased by a sub-division of the contents into two volumes, one referring to theory and practice, and the other dealing with the commercial features only. The index is scanty, but the arrangement of the chapter contents to a large extent redeems this weakness. The style is eminently readable, and remarkable for the entire absence of "spread-eagleism." A good feature, which English writers might copy with advantage, is the sparse occurrence of the names of inventors both real and so-called. A. T. S.

THE DETERMINATION OF CURRENTS IN ABSOLUTE ELECTRO-MAGNETIC MEASURE.

BY G. F. C. SEARLE, M.A.

(Continued from page 543.)

§ 74. **Comparison of Mean Radii of Coils.**—In preceding paragraphs a very full explanation has been given of the important fact that the only fundamental "constant" of a properly designed current-weigher is the ratio of the mean radius of one of the fixed coils to that of the suspended coil. Let us now consider how Lord Rayleigh* determined this ratio with great accuracy. The ratio of the mean radii can be deduced from the ratio of the "galvanometer constants" by the introduction of some small corrections, as was explained in § 29. In § 28, a demonstration was given of the following result:—If a_1 is the mean radius of a coil, supposed of rectangular section, $2k_1$ the radial depth, $2k_1$ the axial depth of the windings, n_1 the number of turns of wire, and G_1 the galvanometer constant, then

$$G_1 = \frac{2\pi n_1}{a_1}\left\{1 + \tfrac{1}{3}\frac{k_1^2}{a_1^2} - \tfrac{1}{2}\frac{k_1^2}{a_1^2}\right\},$$

neglecting powers and products of k_1/a_1, k_1'/a_1, higher than the second. Thus, if the suffix $_2$ distinguishes quantities belonging to the second coil, we have

$$\frac{a_2}{a_1} = \frac{n_2 G_1}{n_1 G_2} \cdot \frac{1 + \tfrac{1}{3}\frac{k_2^2}{a_2^2} - \tfrac{1}{2}\frac{k_2'^2}{a_2^2}}{1 + \tfrac{1}{3}\frac{k_1^2}{a_1^2} - \tfrac{1}{2}\frac{k_1'^2}{a_1^2}}.$$

In Lord Rayleigh's work the quantities k/a, k'/a were quite small, so that an approximate knowledge of their values was sufficient. Thus he found for the suspended coil

$$1 + \tfrac{1}{3}k_2^2/a_2^2 - \tfrac{1}{2}k_2'^2/a_2^2 = 1 + \cdot000741 - \cdot002269 = 1 - \cdot001528,$$

and for the fixed coil

$$1 + \tfrac{1}{3}k_1^2/a_1^2 - \tfrac{1}{2}k_1'^2/a_1^2 = 1 + \cdot000225 - \cdot000457 = 1 - \cdot000232.$$

To compare the galvanometer constants, the two coils are placed with their planes in the magnetic meridian, and their centres coincident. If this setting is carefully made it will be practically perfect, since any error introduced into the ratio by bad adjustment will depend upon the *square* of the displacement from the proper position. In Lord Rayleigh's experiment the uncertainty in the ratio introduced on this score did not amount to more than 1 in 10,000. At the common centre of the coils is hung a very small magnet with a mirror attached to it, so that its motions can be observed in the usual way by the aid of a lamp and scale. The mirror is enclosed in a glass cell, so as to be uninfluenced by air currents. If currents are

* "The Electro-Chemical Equivalent of Silver," *Phil. Trans.*, Royal Soc., 1885.

Digitized by Google

sent round the two coils in opposite directions, it will be possible, by properly adjusting the strengths of the currents, to annul the magnetic force at the centre of the coils due to the two currents. In this case the position of the magnet will be unaffected by the passage of the current. It is important that the magnet should be very short, so that the magnetic field at its ends may not differ sensibly from that at the *centre*. In Lord Rayleigh's experiments the length of the magnet was only 0·1 inch, and the error due to neglecting it could not exceed 1 part in 10,000. The coils are arranged in parallel, as in Fig. 53, a suitable resistance being associated with each coil. If i_1, i_2 be the strengths of the currents flowing through the two coils, then, when a balance is obtained we have $G_1 i_1 = G_2 i_2$, since $G_1 i_1$ is the magnetic force at the centre of the suspended magnet due to the current in the coil (1), and $G_2 i_2$ refers in a similar way to coil (2). But by Ohm's law $R_1 i_1 = R_2 i_2$, so that $G_1/G_2 = R_1/R_2$, R_1 and R_2 being the resistances of the two "parallel" branches.

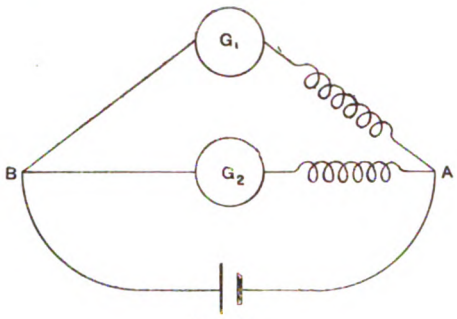

Fig. 53.

To make this method successful there must be some accurate means of determining the ratio of R_1 to R_2. For this purpose Lord Rayleigh arranged the following modification of the arrangements of Fig. 54. The current from a large Daniell cell, A (Fig. 54), after passing the reversing key, B, divides itself at C between the coil D belonging to the electro-dynamometer, and the coil E, the latter being the suspended coil of the current-weigher. The remaining terminals of these coils are led into mercury cups F and H, a resistance box N being associated with the coil E. The terminals of a mirror galvanometer, *g*, are connected to these cups. The cup F is connected to another mercury cup, L, by a standard 10-ohm coil and a resistance box, K, these two being

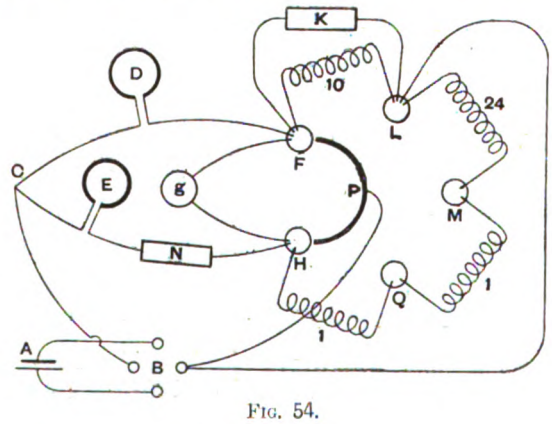

Fig. 54.

arranged in parallel.* The mercury cup, H, is connected to L by means of two standard 1-ohm coils and a 24-ohm coil, whose value is accurately known. The ends of these coils are connected by the mercury cups, Q, M. The current can be led back to the reversing key either from the thick copper horseshoe piece P, which can be inserted into the two cups F, H, or from the mercury cup L. The electro-magnetic balance is first found by inserting P into the cups F, H, and adjusting the resistance N till the position of the spot of light reflected from the mirror at the common centre of the two coils, D, E, is only very slightly affected by the passage of the current. The horseshoe, P, is now withdrawn, so that the current now passes through the standard resistance coils. The resistance in the box K is then adjusted, so that the galvanometer *g* shows no deflection when the current is allowed to pass. It will be noticed that this arrangement constitutes a "Wheatstone's bridge," of which the four "arms" are C F, C H, F L, H L. The operations of finding the electro-magnetic balance and the resistance balance can be so rapidly alternated as to eliminate any error due to changes of temperature in the copper wires.

It is important to note that a knowledge of the *absolute* resistance of the "standard" resistance coils is unnecessary. It is only their *relative* values that are required.

§ 75. **Effect of Self-Induction.**—The electro-magnetic balance cannot be found by making and breaking the battery circuit and attempting to set up a vibration in the magnet suspended at the common centre of the two coils on account of the effects of the self-induction of the coils. On account of this property the currents in the two coils only gradually rise to their final values, and the rates at which they rise are different. Thus, although the magnetic force at the centre of the coils due to the two currents may be accurately zero when the currents have become steady, still, during the time that the currents are being established the magnetic force is by no means zero; and the magnet will be disturbed in the same way as it would if a current of a certain strength were to flow round one of the coils for a very short time. In fact, the effect is the same as if a current of the same strength as the steady current through one of the coils were to circulate round that coil for a time $M\,(1/R_1 - 1/R_2) + L_1/R_1 - L_2/R_2$ seconds,* L_1, R_1 being the coefficient of self-induction and the resistance of one coil, L_2, R_2 similar quantities for the other coil, and M the co-efficient of mutual induction. Lord Rayleigh therefore made no attempt to make the electro-magnetic balance absolutely perfect, but simply found two resistances from the box N differing by about 1/20 ohm, such that the effects observed were reversed in passing from one to the other. The resistance balance, corresponding to each of the two resistances which were taken from the box N, was found by withdrawing the horseshoe P and adjusting the resistance in the box K till the galvanometer *g* showed no deflection. In this way two values of the resistance in K were found such that one was greater and the other less than the resistance, which would have been required for the "resistance balance" if the electro-magnetic balance had been absolutely perfect. From the magnitude of the deflections of the magnet at the centre of the two coils for the two different resistances from N, the required result was obtained by interpolation.

§ 76. **Numerical Example.**—An example will, perhaps, make this clearer. With a certain resistance *a* from the box N the double deflection of the magnet when the battery was reversed amounted to +·8 scale divisions, while with another resistance *b* from N the double deflection was −8·7. Now, with *a* the resistance from K, associated with the [10], and necessary for the resistance balance, had to be such that the resultant resistance of this branch was 9·97772; while with *b* the resultant resistance had to be 9·99182. The resistance which would have been required here if N had been accurately adjusted for the electro-magnetic balance is thus

$$9{\cdot}97772 + {\cdot}8/9{\cdot}5 \times (9{\cdot}99182 - 9{\cdot}97772) = 9{\cdot}97890.$$

* The smallest resistance actually used in the box K was 4,000 ohms. Under these conditions the values of the resistances in the box K need not be known with anything like the accuracy that is necessary for the 10-ohm coil. The method of making a small change in the effective resistance of a coil by arranging a large resistance in parallel with it is very convenient practically, and is very accurate. It was employed by the Electrical Standards Committee of the British Association in their experiments on the absolute unit of resistance, having been suggested to Mr. Fleeming Jenkin by Prof. W. Thomson (now Lord Kelvin). See "B.A. Report," 1863 (Newcastle), or "Reports on Electrical Standards" (Spon, 1873), a valuable book of reference.

* This can be proved by solving the two differential equations

$$R_1 u + L_1 du/dt - M\,dv/dt = E,$$
$$R_2 v - M\,du/dt + L_2\,dv/dt = E,$$

where u, v are the currents in the coils (1) and (2). The "constants" are to be determined by aid of the condition that $u = v = 0$ when $t = 0$. We have also to remember that $G_1/R_1 = G_2/R_2$. The resistance of the battery is supposed negligible.

Digitized by Google

The resistance in the other branch (made up of the coils [1], [1], [24]) was 25·95648, so that the ratio of the galvanometer constants was determined to be

$$25{\cdot}95648/9{\cdot}97890 = 260113.$$

On two other occasions Lord Rayleigh found for the ratio the values 2·60087, 2·60098. The sensitiveness of the method was such that the errors of reading could scarcely exceed one part in 10,000. Lord Rayleigh points out that the weakest part of the arrangement is in the standard resistances. He points out that if it were desired to push the power of the method to its limit it would be necessary to design the two coils so that the ratio should be (approximately) expressible by very simple numbers. "If in the present case, for example, we were content to sacrifice one-fifth of the number of turns on the suspended coil, the ratio might be made to approach that of 2:1. The standard resistances might then be composed of three equal resistance coils, which could be more accurately combined and tested than the more complicated arrangements that we are obliged to use." Employing the formula given in § 74, Lord Rayleigh deduced from the ratio of the galvanometer constants the number 2·42113 as the ratio of the mean radius of one of the fixed coils to the mean radius of the suspended coil. The value of A, the mean radius of the fixed coil, was calculated from the dimensions of the coil to be 24·8106cm., so that the value of a, the mean radius of the suspended coil, came out 10·2473cm. Although these two last numbers are recorded to six significant figures they could not have been accurate to anything approaching that number of figures; but, fortunately, in the current-weigher the only quantity which has to be known with the highest accuracy is the *ratio* of the mean radii of the coils, and this is found very satisfactorily by the method of Bosscha, described above.

(*To be continued.*)

DYNAMO-ELECTRIC MACHINERY.*

BY J. HOPKINSON, F.R.S., AND E. WILSON.†

The following is intended as completion of a Paper by Drs. J. and E. Hopkinson (*Phil. Trans*, 1886, p. 331). The motive is to verify by experiment theoretical results concerning the effect of the currents in the armature of dynamo machines on the amount and distribution of the magnetic field which were given in that Paper, but which were left without verification. For the sake of completeness, part of the work is given over again.

The two dynamos experimented upon were constructed by Messrs. Siemens Brothers and Co., and are identical, as far as it is possible to make them. They are mounted upon a common base plate, their axles being coupled together, and are referred to in this Paper respectively as No. 1 and No. 2.

Each dynamo has a single magnetic circuit consisting of two vertical limbs extended at their lower extremities to form the pole-pieces, and having their upper extremities connected by a yoke of rectangular section. Each limb, together with its pole-piece, is formed of a single forging of wrought iron. These forgings, as also that of the yoke, are built up of hammered scrap iron, and afterwards carefully annealed. Gun-metal castings bolted to the base-plate of the machine support the magnets.

The magnetising coils on each limb consist of 16 layers of copper wire 2mm. diameter, making a total of 3,968 convolutions for each machine. The pole-pieces are bored out to receive the armature, leaving a gap above and below subtending an angle of 68deg. at the centre of the shaft. The opposing surfaces of the gap are 1·4cm. deep.

The following table gives the leading dimensions of the machine:—

	cm.
Length of magnet limb	66·04
Width of magnet limb	11·43
Breadth of magnet limb	38·10
Length of yoke	38·10
Width of yoke	12·06
Depth of yoke	11·43
Distance between centres of limbs	23·50
Bore of fields	21·21
Depth of pole-piece	20·32
Thickness of gun-metal base	10·80
Width of gap	12·06

The armature core is built up of soft-iron discs, No. 24 B.W.G., which are held between two end plates screwed on the shaft.

The following table gives the leading dimensions of the armature:—

	cm.
Diameter of core	18·41
Diameter of shaft	4·76
Length of core	38·10

The core is wound longitudinally according to the Hefner von Alteneck principle with 208 bars made of copper strip, each 9mm. deep by 1·8mm. thick. The commutator is formed of 52 hard-drawn copper segments insulated with mica, and the connections to the armature so made that the plane of commutation in the commutator is vertical when no current is passing through the armature.

Each dynamo is intended for a normal output of 80 amperes 140 volts, at 880 revolutions per minute. The resistance of the armature measured between opposite bars of the commutator is 0·042 ohm, and of each magnet coil 13·3 ohms.

In the machine, the armature core has a greater cross-section than the magnet cores, and consequently the magnetising force used therein may be neglected. The yoke has the same section as the magnet cores, and is therefore included therein, as is also the pole-piece. The formula connecting the line integral of the magnetising force and the induction takes the short form

$$4\pi n c = 2l_2\, \mathrm{I}/\mathrm{A}_2 + l_3 f(\nu \mathrm{I}/\mathrm{A}_3),*$$

where

n is the number of turns round magnet.

c is the current round magnet in absolute measure.

l_2 the distance from iron of armature to rim of magnet.

A_2 the corrected area of field.

I the total induction through armature.

l_3 the mean length of lines of magnetic force in magnets.

A_3 the area of section of magnets.

ν the ratio of induction in magnets to induction in armature.

f the function which the magnetising force is of the induction in the case of the machine actually taken from Dr. J. Hopkinson on the "Magnetisation of Iron," *Phil. Trans*, 1885, Figs. 4 and 5, Plate 47.

In estimating A_2 we take the mean of the diameter of the core and of the bore of the magnets 19·8 cm., and the angle subtended by the pole-face 112deg., and we add a fringe all round the area of the pole-face equal in width to the distance of the core from the pole-face. This is a wider fringe than was used in the earlier experiments (*Phil. Trans.*, p. 337), because the form of the magnets differs slightly. The area so estimated is 906 sq. cm.

l_3 is taken to be 108·8 cm.

A_3 is 435·5 sq. cm.

ν was determined by the ballistic galvanometer to be 1·47. It is to be expected that, as the core is actually greater in area than the magnets, ν will be more nearly constant than in the earlier experiments. It was found to be constant within the limits of errors of observation.

Referring to Fig. 1, the curve C is the curve $x = l_3 f(\nu y/\mathrm{A}_3)$, and the straight line B is the curve $x = 2l_2 y/\mathrm{A}_2$, whilst the full line D is the characteristic curve of the machine $x = 2l_2 y/\mathrm{A}_2 + l_3 f(\nu y/\mathrm{A}_3)$, as given by calculation.

* Abstract of Paper read before the Royal Society.

† It must not be supposed from his name not appearing in this short Paper that my brother, Dr. E. Hopkinson, had a minor part in the earlier Paper. He not only did the most laborious part of the experimental work, but contributed his proper share to whatever there may be of merit in the theoretical part of the Paper.—J. H.

* *Phil. Trans.*, p. 335.

The marks + indicate the results of actual observations on machine No. 1, and the marks 0 the results on machine No. 2, the total induction I being given by the equation :—

$$I = \frac{\text{Potential difference in volts} \times 10^8}{208 \times \text{revolutions per second}}.$$

Experiments made upon the power taken to drive the machine under different conditions show that it takes about 250 watts more power to turn the armature at 660 revolutions when the magnets are normally excited than when they are not excited at all. The volume of the core is 9,465 cub. cm., or in each complete cycle the loss per cub. cm. is

$$\frac{250 \times 10^7}{11 \times 9{,}465} = 24{,}000 \text{ ergs.}$$

The loss by hysteresis is about 13,000 (*Phil. Trans.*, 1885, p. 463) if the reversals are made by variation of intensity of the magnetising force, and the iron is good wrought iron.

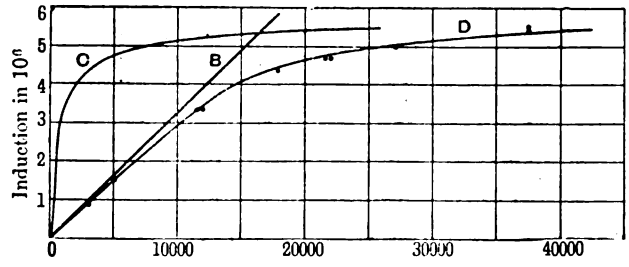

FIG. 1.—Line integral of Magnetising Force.

This result is similar to that in the earlier Paper (p. 352), where it is shown that the actual loss in the core, when magnetised, is greater than can be accounted for by the known value of hysteresis.

Effects of the Current in the Armature.

Quoting from the Royal Society Paper, p. 342, "The currents in the fixed coils around the magnets are not the only magnetising forces applied in a dynamo machine; the currents in the moving coils of the armature have also their effect on the resultant field. There are in general two independent variables in a dynamo machine—the current around the magnets and the current in the armature, and the relation of E.M.F. to currents is fully represented by a surface. In well-

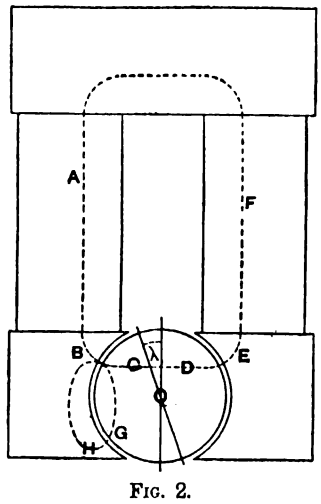

FIG. 2.

constructed machines the effect of the latter is reduced to a minimum, but it can be by no means neglected. When a section of the armature coils is commutated it must inevitably be momentarily short-circuited, and, if at the time of commutation the field in which the section is moving is other than feeble, a considerable current will arise in that section, accompanied by waste of power and destructive sparking.

"Suppose the commutation occurs at an angle λ in advance of the symmetrical position between the fields, and that the total current through the armature be C, reckoned positive in the direction of the resultant E.M.F. of the machine, *i.e.*, positive when the machine is used as a generator of electricity. Taking any closed line through magnets and armature, symmetrically drawn as ABCDEFA (Fig. 2), it is obvious that the line integral magnetic force is diminished by the current in the armature included between angle λ in front and angle λ behind the plane of symmetry. If m be the number of convolutions of the armature, the value of this magnetising force is $4\pi C \frac{m}{2} \frac{2\lambda}{\pi}$ $= 4\lambda m C$ opposed to the magnetising force of the fixed coils on the magnets. Thus, if we know the lead of the brushes and the current in the armature, we are at once in a position to calculate the effect on the E.M.F. of the machine. A further effect of the current in the armature is a material disturbance of the distribution of the induction over the bored face of the pole-piece; the force along B C is by no means equal to that along D E. Draw the closed curved B C G H B, the line integral along C G, and H B is negligible. Hence the difference between force H G and B C is equal to $4\pi C \frac{m}{2} \frac{\kappa}{\pi} = 2\kappa m C$, where κ is the angle C O G."

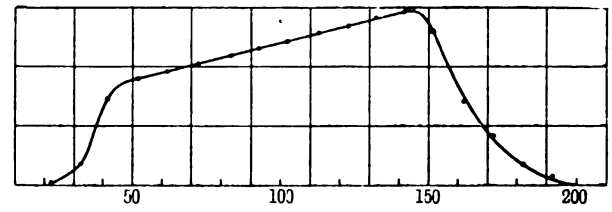

FIG. 3.—No. 1 as Dynamo.

To verify this formula is one of the principal objects of this Paper.

A pair of brushes having relatively fixed positions near together, and insulated from the frame and from one another, are carried upon a divided circle, and bear upon the commutator. The difference of potential between these brushes was measured in various positions round the commutator, the current in the armature, the potential difference of the main brushes, and the speed of the machine being also noted.

The results are given in Figs. 3, 4, 5, and 6, in which the ordinates are measured potential differences, and the abscissæ are angles turned through by the exploring brushes. The potential differences in Fig. 3 were measured by a Siemens voltmeter, and each ordinate is, therefore, somewhat smaller than the true value, owing to the time during which the exploring brushes were not actually in contact with the commutator segments. But this does not affect the results, because the area is reduced in the same proportion as the potential differences. In Figs. 4, 5, and 6 the potential differences were taken on one of Sir William Thomson's quadrant electrometers, and are correct.

Take Fig. 3, in which machine No. 1 is a generator. A centimetre horizontally represents 10 degrees of lead, and the ordinates represent differences of potential between the brushes.

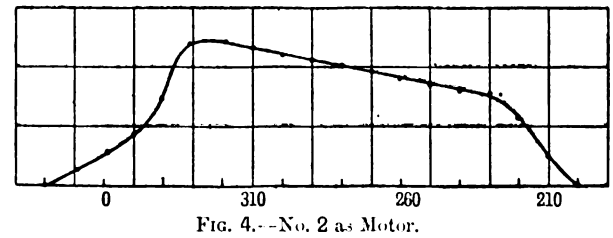

FIG. 4.—No. 2 as Motor.

The area of the curve is 61·3 sq. cm, and represents 130 volts and a total field of $\frac{130}{104} \times \frac{1}{29} \times 10^8 = 4{\cdot}31 \times 10^6$ lines of induction. This is, of course, not the actual field, which is 3 per cent. greater on account of the resistance of the armature, but is represented by an area 3 per cent. greater. An ordinate of 1cm. will represent an induction of $\frac{4{\cdot}31}{61{\cdot}3} \times 10^6 = 7{\cdot}0 \times 10^4$ lines in 10deg. The area of 10deg. is $39{\cdot}5 \times 1{\cdot}73 = 68{\cdot}3$sq.cm.*

* In calculating this area, the allowance for fringe at ends of armature is taken less than before, because the form of opposing faces differs.

Digitized by Google

Hence, an ordinate of 1cm. represents an induction of 1,024 lines per square centimetre. The difference between ordinates at 50deg. and 140deg. is 2·5; hence the difference of induction is actually 2,560. Theoretically, we have $\kappa = \frac{1}{2}\pi m = 104$ C = 9·4. Therefore, $2\kappa m$ C = 3,072, and this is the line integral of magnetising force round curve.

Let A be the induction at 50deg., and A + δ at 140deg.: these also are the magnetising forces. Hence, (A + δ) 1·4 − A 1·4 = $2\kappa m$ C; δ = 2,200 as against 2,560 actually observed.

Take Fig. 4, in which No. 2 machine is a motor. The total field $= \frac{107}{104} \times \frac{1}{20} \times 10^8 = 5{\cdot}15 \times 10^6$ lines of induction. Since the area of the diagram is 53·5 sq. cm., an ordinate of 1cm. $= \frac{5{\cdot}15}{53{\cdot}5} \times 10^6 = 96 \times 10^4$ lines of induction in 10deg. Hence,

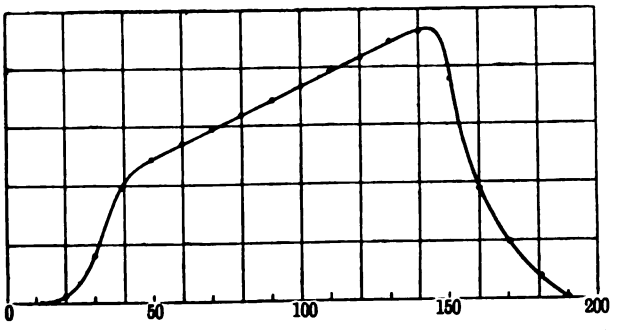

Fig. 5.—No. 1 as Dynamo.

an ordinate of 1cm. represents an induction of $\frac{9{\cdot}6 \times 10^4}{68{\cdot}3}$ = 1,400 lines per sq. cm. The difference between ordinates at 320deg. and at 230deg. is 2·0; hence, the difference of induction is actually 2,800. Theoretically we have $\frac{2\kappa m \text{C}}{l}$ $= \frac{3\frac{1}{2} \times 104 \times 11{\cdot}4}{1{\cdot}4} = 2{,}666$, as against 2,800 actually observed.

In Fig. 5 No. 1 machine is a generator. The total field $= \frac{52}{104} \times \frac{1}{12{\cdot}6} \times 10^8 = 3{\cdot}97 \times 10^6$ lines. The area of the diagram is 90·9 sq. cm., and therefore an ordinate of 1 cm. $= \frac{3{\cdot}97}{90{\cdot}9} \times 10^6 = 4{\cdot}37 \times 10^4$ lines in 10deg. Hence, an ordinate of 1 cm. represents an induction of $\frac{4{\cdot}37 \times 10^4}{68{\cdot}3} = 639$ lines per sq. cm. The difference between ordinates at 50deg.

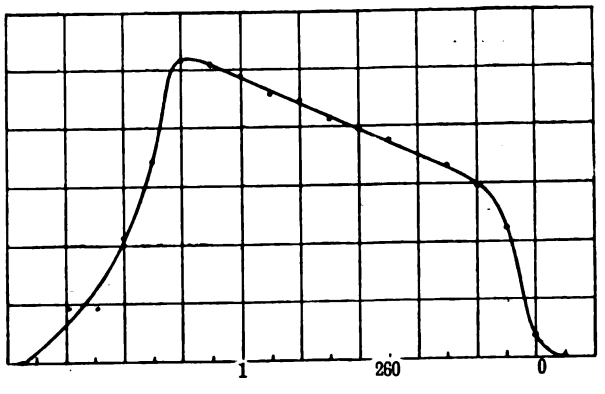

Fig. 6.—No. 2 as Motor.

and at 140deg. is 4·5; hence, the difference of induction is actually 2,877. Theoretically, we have $\frac{2\kappa m \text{C}}{l} = \frac{3\frac{1}{2} \times 104 \times 12{\cdot}9}{1{\cdot}4}$ = 3,010, as against 2,877.

In Fig. 6 No. 2 machine is a motor. The total field = $\frac{63{\cdot}5}{104} \times \frac{1}{12{\cdot}3} \times 10^8 = 4{\cdot}96 \times 10^6$ lines. The area of the diagram 112·2 sq.cm., and therefore an ordinate of 1cm. $= \frac{4{\cdot}96}{112{\cdot}2} \times 10^6$ $= 4{\cdot}42 \times 10^4$ lines in 10deg. Hence, an ordinate of 1cm. represents an induction of $\frac{4{\cdot}42}{68{\cdot}3} \times 10^4 = 647$ lines per sq. cm. The difference between ordinates at 323deg. and at 233deg. is 4·2; hence, the difference of induction is actually 2,718. Theoretically, we have $\frac{2\kappa m \text{C}}{l} = \frac{3\frac{1}{2} \times 104 \times 12{\cdot}3}{1{\cdot}4} = 2{,}870$, as against 2,718 actually observed.

At page 345 of the Paper on Dynamo-Electric Machinery it is shown that

$$\text{I} + \frac{\nu - \text{I}}{\nu} 4\lambda m \text{C} \frac{\text{A}_2}{2 l_2} = \text{F}\left(4\pi n c - \frac{4\lambda m \text{C}}{\nu}\right),$$

where I = F $(4\pi n c)$ is the characteristic curve when C = 0, and λ is the lead of the brushes.

The following is an endeavour to verify this formula. The potentials both upon the magnets and upon the brushes were taken by a Siemens' voltmeter, and are rough. The speeds were taken by a Buss tachometer, and there is some uncertainty about the precise lead of the brushes, owing to the difficulty in determining the precise position of the symmetrical position between the fields, and also to the width of the contacts on the commutator.

It was necessary, in order to obtain a marked effect of the armature reaction, that the magnet field should be comparatively small, that the current in the armature should be large, and the leads of the brushes should be large.

The two machines had their axles coupled so that No. 1 could be run as a generator, and No. 2 as a motor. The magnets were in each case coupled parallel, and excited by a battery each through an adjustable resistance. The two armatures were coupled in series with another battery, and the following observations were made:—

—	Potential on magnets in volts.	Potential on brushes.	Speed per minute.	Current in amperes.	Lead of brushes.
No. 1	24—24	66—67	880	102—103	26°
No. 2	29—29	86—84	880	102—103	29°

From which we infer:—

—	Current in magnets.	$4\pi n c$.	Corrected potential for resistance of armature.	Total induction I.
No. 1	1·78	8,900	70·8	$2{\cdot}30 \times 10^6$
No. 2	2·15	10,750	80·7	$2{\cdot}65 \times 10^6$

As there was uncertainty as to the precise accuracy of the measurements of potential, it appeared best to re-measure the potentials with no current through the armature with the Siemens' voltmeter placed as in the last experiment. Each machine was, therefore, run on open circuit with its magnets excited, and its potential was measured.

—	Potential on magnets in volts.	Potential on brushes.	Speed per minute.	Potential at 880 revs.
No. 1	25—25	90—90	880	90·0
No. 2	28—28	79—80	715—710	98·2

From which we infer, since we are upon a part of the characteristic which is practically straight; in which case, of course, the formula is reduced very nearly to

$$\text{I} = \frac{\text{A}_2}{2 l_2}(4\pi n c - 4\lambda m \text{C}).$$

—	Potential on magnets.	Potential on brushes.	Induction I = F$(4\pi n c)$.
No. 1	24	86·4	$2{\cdot}82 \times 10^6$
No. 2	29	101·7	$3{\cdot}30 \times 10^6$

Digitized by Google

We have further :—

$\lambda = 0{\cdot}45$ for No. 1. $\lambda = 0{\cdot}5$ for No. 2.

$\frac{4\,m\,C}{\nu} = 2{,}920.$ $\frac{\nu - 1}{\nu} 4\,m\,C\,\frac{A_2}{2l_2} = 443{,}800.$

It has already appeared that experiment gives for I in No. 1 $2{\cdot}3 \times 10^6$, and in No. 2 $2{\cdot}65 \times 10^6$. The difference is probably due to error in estimating the lead of the brushes, which is difficult, owing to uncertainty in the position of the neutral line on open circuit.

—	$\frac{4\lambda m C}{\nu}$.	$\frac{\nu-1}{\nu} 4\lambda m C \frac{A_2}{2l_3}$.	$4\pi nc - \frac{4\lambda m C}{\nu}$.	$F\left(4\pi nc - \frac{4\lambda m C}{\nu}\right)$.	$F\left(4\pi nc - \frac{4\lambda m C}{\nu}\right) - \frac{\nu-1}{\nu} 4\lambda m C \frac{A_2}{2l_2}$.
No. 1 ...	1314	199700	7586	$2{\cdot}41 \times 10^6$	$2{\cdot}21 \times 10^6$
No. 2 ...	1460	22.900	9_90	$2{\cdot}90 \times 10^6$	$2{\cdot}68 \times 10^6$

LOAD DIAGRAMS OF ELECTRIC TRAMWAYS, AND THE COST OF ELECTRIC TRACTION.*—By A. Reckenzaun.

(*Concluded from page 579.*)

The Americans, as you are well aware, are far ahead of us in matters relating to tramways; they count their electric roads by hundreds, and their electric cars by thousands. I need not enlarge here upon figures well known to all readers of engineering literature, but I venture to point to recent statistics on working expenses, and especially to those prepared by Mr. J. S. Badger for the Street Railway Convention last October when meeting at Pittsburgh. Mr. Badger gave an immense amount of data, all systematically arranged, of which Table V. is an abstract, converted into Eng.ish equivalents as to money values. Those interested in all its details will find a reprint of this elaborate communication in the *Electrical World* of October 31, 1891. Indeed, in order to fully appreciate the data contained in Table V., certain descriptive matter should accompany it; and this deals with the number and sizes of boilers, engines, dynamos, the quality and price of coals, condition of road and track, sizes and number of cars, total mileage, and wages in various localities. I merely give the most essential ones.

Road No. 1 has a generating station containing four boilers, one 250 H.P. Corliss engine, one 150 H.P. Ball engine, one 150 H.P. Brown engine, and two Edison generators. The line runs through five miles of streets, and the steepest gradient is 13·2 per cent., 100ft. long. There are 36 motor cars of the ordinary size, of which 20 are in daily use, making annually 601,966 miles. The price of coal is 8s. 4d. per ton, and the consumption 7lb. per car mile.

Road No. 2: Four boilers, two Taylor-Beck engines of 125 H.P. each, one of 175 H.P., one Armington and Sims of 250 H.P.; five Edison dynamos. Track, six miles long; steepest gradient, 9·25 per cent. for 400ft. 18 motor cars, of which 16 are in daily use, making an annual mileage of 724,000. Price of coal, 7s. 3d. per ton; consumption, 11lb. per car mile.

Road No. 3: Eight boilers; nine steam engines, of which five are of 125 H.P. and two 100 H.P., all of the Phœnix type; also two 125-H.P. Beck engines. Nine Edison and seven Thomson-Houston dynamos supply current for 50 motor cars in daily use, making an average of 1,819,000 miles per annum. There are altogether 53 motor cars, of which four were supplied by Westinghouse, 20 by Edison, and 29 by the Thomson-Houston Company. Steepest grade, 8 per cent. for 800ft.; total length of streets traversed, 35 miles. Cost of coal, 11s. 2d.; and the consumption of fuel is calculated to be 12·2lb. per car mile.

Road No. 4: Two boilers and three 150-H.P. Ball engines, driving six dynamos. Length of streets run through, 14 miles, with 18 motor cars, making annually 700,000 miles. There is one steep gradient of 10 per cent. rise for 775ft. Coal, in this case, costs 8s. 9d., and the amount used per car mile is only 6·4lb.

The fifth road, out of seven given by Mr. Badger, is only four miles long, with five passenger cars and one freight car. It has only been running for nine months up to the date of the report. The coal costs 12s. 8d. to 15s. 10d. per ton; water, 5d. per 1,000 gallons. The wages on all the above lines varied between 40s. and 60s. per week for drivers, conductors, and mechanics.

The most important of all the American electric tramways is that of the West End Railway Company of Boston, where they have now 400 electric cars in operation. Table VI. gives a comparative statement of gross receipts and working expenses of the electric cars and horse cars in the city of Boston for five months ending August, 1891. No detailed account is given, but the rolling stock is continually being increased, and the central-power station in course of construction will contain engines capable of converting 12,000 H.P. into electrical energy. All the American lines referred to are worked on the overhead conductor principle.

I have intentionally omitted comparisons between electric traction and various modes of mechanical traction, such as cable, steam, and compressed air. Our object in this Institution is to inquire into the merits of systems involving the use of electricity, and to further their extension in every legitimate way, and with this point in view I have endeavoured to collect and bring before you such data as may tend to increase the general interest in one important branch of our profession.

* Paper read March 24, 1892, before the Institution of Electrical Engineers.

AUTHORISED ABSTRACT.—March 24, 1892.

Mr. MACMAHON, of the City and South London Railway Company, had not found such large variations of the volts as Mr. Reckenzaun mentioned. In his own practice he had occasionally found as much as 130 volts variation when running his dynamos simple-shunt, or when the belt slipped; but when running compound the maximum range was from 420 to 500. Mr. Reckenzaun's curves were obtained from readings taken every five

Digitized by Google

seconds; if they had been taken by a recording instrument they would, he thought, have been found very much more rounded; the tops of the peaks being often quite flat for two seconds together. The current curve of a line when eight cars are on at once, he had found to show comparatively moderate variations, say, from 100 to 300 A, and never dropping below 80. When the number was reduced to five cars the current was very irregular and frequently dropped to zero. With ten or more cars, and volts varying proportionately to what they now do for five cars, he thought the average variation would not exceed 10 per cent. He did not believe in the use of accumulators as steadiers, and considered them as rather a nuisance.

Mr. M. VOLK said it was desirable to equalise the load on the engine as far as possible, as it was very uneconomical to have the latter several times more powerful than was required for the average load. He said that at Brighton he had a one-ton fly-wheel running at 160 revolutions on a 12 H.P. engine, and was able to start two cars at once; whereas, with a light fly-wheel, the attempt would have pulled the engine up. The cost at Brighton was about 4d. per car mile, running 23,000 car miles per annum. It was an edge-rail track, and required less power.

Mr. GRAFF BAKER, of the Thomson Houston Company, said that the German figures in the Paper were new to him. Mr. Reckenzaun had referred to the low cost of labour there as compared to America. How did the cost of labour and fuel in Germany compare with that in England? In putting down a plant in England, the data obtained from American experience had to be much modified. He had obtained from America a motor which had given very good results there, and had found that it was not nearly so satisfactory in Leeds, where he used it in November on different rails and muddy streets. He employed a large staff to investigate the results, and ascertain the differences of the conditions compared with American practice. His expenses were, therefore, much greater than those of a purely commercial line. On this account he hesitated to give the figures that Mr. Reckenzaun had asked for without prefacing them with the explanation of how it was that they were so much in excess of the American ones, where everything was cut and dried. The following costs per car mile were obtained from an average fortnight's run. General expenses (salaries, office expenses, &c.) 1·13d., transport expenses (including drivers, conductors, and inspectors), 5·17d., maintenance of equipment 0·33d. He had some difficulty in getting a competent staff accustomed to motors, and had been obliged to get two men at high wages from America to instruct them; his head engine driver alone got £3. 10s. per week. Their engine, too, was running much under its full load (a 200 H.P. engine running at 75 H.P.). Five cars were plenty to do the work all the week, but on Saturday and Sunday 50 or 60 would not be too many. He sometimes had 116 people on a 60ft. car. The maintenance was principally for new wheels, the original ones not being suitable for Leeds.

Mr. STUART RUSSELL showed a diagram of currents on the Hague-Schevening* line. Outside the town, running at about 14 miles per hour

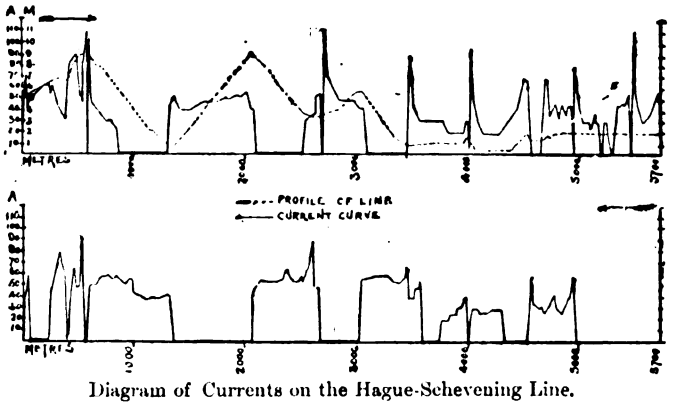

Diagram of Currents on the Hague-Schevening Line.

on T-headed rails, the tractive force on a straight level was about 20lb. per ton. In towns the speed was seven miles per hour. The cars weighed 17 tons (including batteries and passengers); 200 cells were used, two in parallel in town, and all in series outside. Each run (about 30 minutes) required about 20 ampere hours, of which 9 ampere hours were expended in starting from rest and getting up to normal speed. The starts averaged five or six per mile. The average H.P. over the run out and back was about 13. In reply to Mr. Kapp that 17 tons per car was exceptionally heavy, Mr. Russell said that this included 200 cells and 60 passengers.

Mr. DOLBY thought that a great deal of power was lost in starting from rest with a rigidly geared motor, and thought it would effect a great saving if the motor were allowed to attain its normal speed, and were then put on by friction gear with considerable slip at first.

Mr. MANVILLE thought that the engine might be spared a good deal of strain by the use of a set of accumulators; not the ordinary expensive type but plain lead plates; these would charge when the load suddenly dropped and would help the engine for a short time when a number of cars were started at once. Electric trams would, he said, never be really successful as long as a clause for the protection of the telephone companies prevented the use of earth return. It was practically impossible to run a two-wire overhead line. A Birmingham Company had dropped their Bill on account of being unable to get the clause omitted. In America they recognised the principle that the roadways were first of all for traffic.

Mr. RUSSELL wished to know the weight of the Thomson-Houston cars.

The discussion was adjourned.

PHYSICAL SOCIETY.

At a meeting of this Society on March 25, 1892, Prof. S. P. THOMPSON, Vice-President, in the Chair, a Note

"On the E.M.F.'s of Gold and Platinum Cells"

was read by Prof. E. F. HERROUN. The few experimenters who have tested such cells arrived at different conclusions; hence the author examined experimentally zinc-platinum and zinc-gold cells, the metals being immersed in solutions of their chlorides of equal molecular strength. From Thomson's thermo-chemical data, the E.M.F. of such a zinc-platinum cell should be 1·548 volts, whilst experiments gave values between 1·70 and 1·473 according to the previous history of the cell. This high value, and the uncertainty of the E.M.F. after sending a current, the author believed due to dissolved oxygen. Other experiments showed that gold is slightly electropositive to platinum in water or dilute HCl., but in *aqua regia* the positions are reversed.

DISCUSSION.

Prof. AYRTON said the experimental E.M.F.'s were fairly close to the theoretical values, and thought the differences might arise from occlusion of gases, which, although not taken into account in the thermo-chemical experiments, might have considerable effect on the electrical values. Platinum especially had remarkable occluding properties.

The CHAIRMAN (Dr. Thompson) believed that some discrepancy between the calculated and observed values of the E.M.F.'s might be due to the calculations only being carried to the first degree of approximation. The complete expression contained, amongst others, a term depending on the temperature co-efficient of the cell.

Dr. HERROUN, in reply, said care was taken to expel as much of the occluded gas as possible before using the plates, and no gases were formed in the re-actions. To Dr. Thompson he pointed out that Clark's cell had an E.M.F. greater than that calculated from thermo-chemical data; hence the temperature coefficient ought to be positive, but as a matter of fact it was negative. The discrepancy between the calculated E.M.F. and the observed he believed due to inaccurate determinations of the thermo-chemical constants of mercury salts.

A Paper on

"Some Electrical Instruments,"

was then read by Mr. R. W. PAUL, a full report of which will be found in our last issue.

DISCUSSION.

Mr. SWINBURNE inquired whether the plan of using two vertical magnets to form an astatic system had been tried, and with what result. He also asked if dial bridges made with switches instead of plugs would not be advantageous.

Dr. SUMPNER said vertical needles had been used at the Central Institution and found satisfactory.

Mr. A. P. TROTTER wished to know for what purpose the galvanometer was intended, since it appeared that the coils were wound with a minimum amount of wire. A galvanometer was often required for many different purposes, and it did not follow that one with a minimum amount of wire was the best all-round instrument.

Mr. C. W. S. CRAWLEY made inquiries as to the magnitude of the block error in the form of the Wheatstone bridge shown, for he thought the flexible cords would make it considerable. In reply to Mr. Swinburne he said he had found the variations in switch bridges greater than in plugs.

Prof. S. P. THOMPSON thought it was not generally known that the best shape of galvanometer coil depended on whether the instrument was to be used as an ammeter or voltmeter. The shape determined by Sir W. Thomson was a voltmeter coil; that for an ammeter was much shorter axially.

Mr. PAUL, in reply, said he used one or other shape of coil according to the use for which the galvanometer was intended. The block error in the Wheatstone bridge was very small and quite negligible for most purposes. When very great accuracy was required the error, being constant, was easily measured and allowed for.

LEGAL INTELLIGENCE.

King, Brown and Co. v. the Anglo-American Brush Electric Light Corporation.

JUDGMENT.

In the House of Lords, on Tuesday, their Lordships delivered judgment in this case. The appellants carried on business at No. 6, York-place, Edinburgh, and the respondents at the Rosebank Electric Works, Broughton-road, Edinburgh; and the question raised was whether the letters patent, No. 2,003 of 1878, granted to Mr. Herbert John Haddan, for an alleged communication from Mr. Charles Brush abroad, and twice amended and disclaimed, were invalid. The Judges of the First Division of the Court of Session, Edinburgh, held that the patent was invalidated in its essential and fundamental privilege, by reason of the prior publication and prior use by Mr. Samuel Alfred Varley of the invention of compound winding, for which the exclusive privilege was given, and they affirmed the Lord Ordinary's interlocutor. The Anglo-American Brush Electric Light

Digitized by Google

Corporation appealed to their Lordships against that decision, and the appeal was heard at the end of last year, when judgment was reserved.

The Attorney-General (Sir R. Webster, Q.C.) Mr. Moulton, Q.C., and Mr. Graham appeared for the appellants; while the Solicitor-General for Scotland (Mr. A. Graham Murray, Q.C.), and Mr. A. Daniell opposed it on behalf of the respondents.

The LORD CHANCELLOR, in delivering judgment, said: This is an appeal against an interlocutor of the First Division of the Court of Session, affirming the interlocutor of the Lord Ordinary, setting aside the patent, of which the appellants are the assignees, on the ground that the portion of the invention patented (with which, under the circumstances, it is alone material to deal) had been previously published. The patent to set aside is known as Brush's patent, and bears date November 16, 1878; and the question in debate is whether a patent taken out by Mr. Samuel Alfred Varley in 1876 does or does not so anticipate the patent of 1878, of which the appellants are the assignees, as to make the latter patent bad. The patent has relation to the particular form of dynamo-electric machines, all of which have, and were known to have before the date of either patent, this principle in common, that they move magnets past coils of wire or coils past magnets, with sufficient velocity to produce the desired result. It was also familiar knowledge before the date of either patent that a current of electricity sent round a bar of soft iron would render the bar of iron magnetic. Undoubtedly, the progress of electrical science has given rise to various forms of using the energy, in which the two principles to which I have adverted have become important, and the practical application of them by means of different mechanical devices has for some time past exercised the ingenuity of practical electricians. One appears to have been the idea of making one wire go round the iron bar, make it and maintain it as a magnet, making the same wire go to perform whatever work it was intended to perform, and returning to the magnet, the single current thus doing two things. The further step was made when what was called the shunt apparatus was invented. The current of electricity was divided into two. One stream, so to speak, was made to go round the iron bar, keeping it magnetic, while the other was led to do the work which it was required to do, and were re-joined after the work had been accomplished. Mr. Imray explains with great clearness what are the two principles called series and shunt-winding. On the machine being revolved, he says, a wire wrapped round and round the magnet crosses over to another magnet, proceeds to do whatever work is required of it in what is called the external or working circuit, and goes back again after doing the work. It is called "series" winding, because the coils of the electro-magnet are in series with the external circuit; that is to say, it is one continuous wire. The current goes straight from start to finish. The whole electricity produced by the machine goes to excite the magnet and to the external wire, and straight from the one to the other. The weak point of it (said Mr. Imray) is this: that as soon as you break the external circuit you will cease to have an electric machine, because there is no current. In electrical language, that is spoken of as having the external circuit opened. When the external circuit is broken or opened, the current ceases to flow, and you do not have the advantage of any magnetising action by the current going around the magnets of the machine. In the same way, the more resistance you put in your external circuit, that is to say, the more work you ask your machine to do, the less current will flow through the external circuit; and the more work you have, the less you will be doing towards the magnetising of your machine. Resistance in wire mainly depends: first, upon the character of the wire and what metal it consists of; secondly, upon its transverse section; and, thirdly, upon its length. The longer the wire the greater the resistance; the smaller the section the greater the resistance; one kind of metal has more resistance than another. Roughly speaking, a short thick wire has much less resistance than a long thin one. Another form is what is called "shunt-winding," in which the difference is simply in the disposition of the wires. The current coming away, is split into two. One portion of it goes to what has been called the external circuit, doing whatever is to be done, and having done that work returns to the machine, but without any actual contact with the magnets of the machine at all. The other portion goes straight to the magnet, is wrapped round it as before, and then returns to the brush, as it is called, without any contact with the external circuit at all. The strong point (says Mr. Imray) of this arrangement is that, whether the external circuit is open or closed, there is always magnetism in the wire capable of producing electricity, because the current is continually running through the shunt to the magnet. A defect in it is that some of the electricity is taken away from the external circuit which otherwise would go through it. One further explanation of Mr. Imray's becomes necessary to follow the question with which your Lordships have to deal, and that has reference to what Mr. Imray says is variously known as "electromotive force," "tension," "pressure," and "potential." "Potential" seems to be the word generally used, and means the intensity of pressure by which the electricity is caused to pass along a conductor. The advantage of what is called a compound winding, which is neither more nor less than a combination of the two previously described, the first being known as "series," the second as "shunt," and the one in debate as "series-shunt," or compound winding. The advantage of the arrangement is in producing a constant pressure, or an equal volume, or an even current. It is difficult, except by finding analogies in other subjects of physical research than electricity, to convey the exact idea, but the advantage attained, at all events, is that when the work is changed in the outer circuit the amount of current that goes round the magnet is so changed that one compensates, or nearly compensates, for the other.

Now in the patent, patented in 1876, Mr. Varley says:—"Part of the electricity developed by the machine is *diverted*" and the word is significant) "to maintain the magnetism of the soft iron magnets, and the remaining portion is used to produce the electric light. There are several well-known ways of doing this" (this has been the subject of very violent comment), "but the method I prefer is to wrap the soft iron magnets with two insulated wires, one having a *larger* resistance than the other. The circuit of larger resistance is always closed, and the circuit of *less* resistance used for the electric light. When the electric light is being produced the greater portion of electricity passes through the circuit of less resistance which I term 'the electric light circuit,' maintaining the magnetism of the magnets and producing the light. When the electric light circuit is opened from any cause, the electricity developed passes through the circuit of greater resistance only, and maintains the magnetism of the magnets." It is impossible to deny that in the present state of electrical knowledge dealing with dynamos but that the description given undoubtedly does disclose to anybody familiar with the principle of electro-dynamos and the medium by which the electric current is turned to account, points to the very thing for which the patent was granted to Mr. Brush. But it is said that, for the purpose of judging of the novelty of the invention of 1876, one must, as nearly as one can apply oneself to the knowledge existing at that date, and not apply what we have learned since, so as to interpret the language of the patent of 1876 by the light of later discoveries. I am not quite certain that I understand the application to this case of that principle of interpretation, which, however, I admit to be sound. The "series" was known, the "shunt" was known, and the language seems to me incapable of any other interpretation than that the patentee did mean to combine the two previously known systems. If he did, and disclosed the mode of doing it, the novelty of the later patent cannot be supported. I confess that I am unable to entertain a doubt that it was so disclosed. What he intended was, I think, conclusively shown by the original rough sketch produced. Distinguished electricians cavil at the mode of its disclosure, criticise the language (which is not, perhaps, the most felicitously chosen), and possibly suggest doubts as to what would have been the fate of Mr. Varley's patent if it had been attacked upon the ground of the insufficiency of the specification; but that is not the question to be determined here. The question is the disclosure of the invention, which consisted in the combination of two known forms of dynamo-electric machines. I doubt whether there is much to choose in clearness of exposition between the one patent and the other. I think it is certain that neither the one patentee nor the other had any very definite notion of the importance of the invention until a year or two later. The invention of the incandescent light brought into prominence the importance of an even, uniform, and continuous flow of the electric energy. I am, therefore, of opinion that the interlocutor appealed from ought to be affirmed.

I have confined myself, however, in arriving at this conclusion to the specifications themselves, aided by scientific witnesses, in interpreting the scientific nomenclature in which the specifications are couched, and the explanations of the witnesses as to the operations produced by the different forms adopted. I designedly avoid giving any opinion upon the question of the user of Varley's machine. Many questions, to my mind, arise as to which publication there was from the use of that machine, as a machine disclosing the mode by which the electric light was produced. But inasmuch as I have come to the conclusion that I have indicated, it is not necessary further to discuss the extent to which the use of the electric light by means of Varley's machine for the purpose of illustrating some submarine invention, was such an exhibition or publication of it as would make a subsequent patent void. I therefore move your Lordships, that the interlocutor appealed from be affirmed, and this appeal dismissed with costs.

LORD WATSON said: The applicants are assignees of Brush's patent of 1878, for improvements in apparatus for the generation and application of electricity for lighting, plating, and other purposes. The patent originally included two different dynamo-electric apparatus, now known respectively as the shunt and the series-shunt; but in 1882, the appellants, having become aware of the fact that their shunt-winding machine had already been fully described and claimed in Clark's Patent of 1875, amended their specification by disclaiming that part of it which related to shunt winding, and limiting their claim to the series shunt. In this appeal they complain of a decision of the First Division of the Court of Session, affirming an interlocutor of the Lord Ordinary (Trayner), by which he reduced and set aside their letters patent as amended by disclaimer, on the grounds, *inter alia*, that the series-shunt apparatus therein described had been published in Varley's patent of 1876, and also that there had been prior public user. Dynamo-electric machines are useful for various kinds of work, but are now chiefly employed for producing light. I shall, in so far as it may be necessary to describe such machines, refer to them as if they were used for the latter purpose. At the date of Clark's patent, the only known variety of self-exciting dynamos was the series-winding apparatus, in which the current of electricity generated in the revolving coils after it was passed through the commutator, is conducted to and round the magnets and thence to the lamps, from which it returns to the machine, thus forming a single electric circuit, which performed the double function of magnetising the magnets and doing work. In the shunt apparatus, the volume of electricity, after it has passed the commutator, is divided into two unequal currents by means of a shunt, or bifurcation of the conducting wire, which is, in itself, a common device. The smaller current is then made to circulate round the magnets, whilst the larger is led to the lamps; and they are again united, just before they re-enter the machine. So that these currents form two separate circuits, that of greater resistance maintaining the supply of electric force in the magnets, and that of lesser resistance producing light. The series-shunt-winding apparatus is, as its name imports, a combination of the two systems already described. Its arrangements are practically the same with those of the shunt-winding machine, subject to this modification, that after bifurcation, the larger current, instead of being taken direct to the lamps, is, in the first instance, made to encircle the magnets. Accordingly, the smaller current serves for excitation only, as in the shunt system; whereas the larger current serves both for excitation and for work, as in the series-winding system. Whether the series-shunt system was first disclosed to the public by

Digitized by Google

Varley in 1876, or by Brush in 1878. it seems to be certain that the real merit of the arrangement was neither understood nor appreciated until the subsequent discovery of the incandescent lamp. The efficiency of that mode of lighting depends upon the light produced by the incandescent filaments of carbon, and the maintenance of a uniform and steady flow of electricity in the working circuit, which is now termed a constant potential. In the series, and also in the shunt system, the working current is liable to considerable variation; with this difference, that the same disturbing elements which in the one case cause a decrease, in the other occasion an increase of E.M.F. The combination of these opposite tendencies brings into play the principle of compensation, and makes it possible, by careful adjustment, to attain a more constant potential with the series-shunt than with either of its component systems.

The terms of Brush's specification indicate that the patentee had not in his view the attainment of that high degree of constancy in the motive force which is desirable for the purpose of incandescent lighting. He points out that other machines were "not well adapted for certain kinds of work, notably that of electro-plating," and then proceeds to describe his own in these terms:—"I attain my object by diverting from external work a portion of the current of the machine, and using it either alone or in connection with the rest of the current for working the field magnets. I prefer the latter plan of the two, especially for electro-plating machines." In other words, he attains his object by using either the shunt or the series-shunt, but prefers the latter for electro-plating. For other purposes than electro-plating, he does not suggest that the one system is in any respect greatly preferable to the other. As matter of fact, it appears to be doubtful which of the two is most suitable for plating. Mr. Preece, one of the appellants' skilled witnesses, says: "Pure shunt is preferred in England for electro-plating. In America the compound is preferred."

In Varley's patent of 1876 no claim is made either for shunt or for series winding. The passage which has been held, by both Courts below, to anticipate the invention claimed by the appellants is merely descriptive of the machines to which the arrangements claimed by Varley may be usefully applied, and is in these terms: "Part of the electricity developed by the machine is diverted to maintain the magnetism of the soft-iron magnets, and the remaining portion is used to produce the electric light. There are several well-known ways of doing this, but the method I prefer is to wrap the soft-iron magnets with two insulated wires, one having a larger resistance than the other. The circuit of larger resistance is always closed, and the circuit of less resistance is used for the electric light. When the electric light is being produced, the greater portion of electricity passes through the circuit of less resistance. which I term 'the electric light circuit,' maintaining the magnetism of the magnets, and producing light. When the electric light circuit is opened, from any cause, the electricity developed passes through the circuit of greater resistance only, and maintains the magnetism of the magnets." In estimating the real significance of Varley's specification, it is necessary to consider what amount of information with respect to dynamo-electric apparatus ought to be attributed to persons who had an opportunity of reading it in the year 1876. The language used by the patentee must be construed with reference to the information then open to the public, and not in the light of subsequent discoveries. To my apprehension, it does not admit of doubt that a reader, acquainted only with series-winding, might not attach the same meaning to the words used by Varley, as would naturally occur to one who was also familiar with the shunt, or with the shunt and series-shunt systems of winding.

Since the hearing of this appeal, I have carefully perused the whole evidence adduced by both parties, in so far as it has any bearing upon the issue of prior publication. Of the respondents' evidence it is sufficient to say that it is in entire accordance with the decision appealed from. The appellants' evidence consists of oral testimony by electricians of great eminence, and is directed mainly, if not wholly, to prove (1) that, on a fair construction of the specification of 1876, the words relied on by the Court of Session do not disclose either shunt or series-shunt winding, and (2), assuming them to do so, that the specification does not contain explanations or directions which would enable a workman of ordinary skill to construct either a shunt or a series-shunt machine. I need hardly say that it is for the Court, and not for the witnesses, to construe the terms of the specification; and that their evidence upon the first of these points is only material in so far as it may supply scientific facts which ought to be taken into account in arriving at the true construction of the instrument. There is one circumstance which, in my opinion, seriously affects the value of the appellant's evidence on both points. The testimony of their witnesses was given upon the footing that, in 1876, Clark's invention of the previous year was still unknown, and that those who read Varley's specification could have no knowledge of any system other than series winding. Upon that assumption it occurs to me that a reader, whether a man of science or skilled workman, would probably have been at a loss to discover what Varley meant, and might not have arrived at either shunt or series-shunt winding without some exercise of his inventive faculty. I am, however, unable to find any good reason for holding that Clark's shunt machine was unknown in the year 1876. It is true that in 1878 Mr. Brush had never heard of Clark's invention, and also that shunt winding was unknown to Sir W. Thomson before 1879. But it appears to me that Clark's taking out a patent for his invention was, both in fact and law, a publication of it. I do not suppose that every electrician, however eminent, is by necessity personally cognisant of every invention patented within the bounds of his science; and the ignorance of two or more of them is unavailing to prove that the knowledge of others was equally defective. I cannot, therefore, avoid the conclusion that, in 1876, Clark's shunt-winding machine had been disclosed to the public, and must have been known to some, if not to all, electricians; and, consequently, that the uncontroverted passage in Varley's specification ought to be construed on the footing that shunt-winding was known at its date. I do not think it necessary to deal with the conflict of testimony as to the sufficiency of Varley's specification for the guidance of a skilled workman. The Lord Ordinary was of opinion that the appellants had failed to prove that part of their case. But I agree with his Lordship, and with the learned Judges of the First Division, in holding that the sufficiency, or insufficiency, of the specification for that purpose does not afford a crucial test of prior publication. Every patentee, as a condition of his exclusive privilege, is bound to describe his invention in such detail as to enable a workman of ordinary skill to practise it; and the penalty of non-compliance with that condition is forfeiture of his privilege. His patent right may be invalid by reason of non-compliance; but it certainly does not follow that his invention has not been published. His specification may, notwithstanding that defect, be sufficient to convey to men of science and employers of labour information which will enable them, without any exercise of inventive ingenuity, to understand his invention, and to give a workman the specific directions which he failed to communicate. In that case, I cannot doubt that his invention is published as completely as if his description had been intelligible to a workman of ordinary skill.

Assuming as, in my opinion, I am bound to do, that Clark's invention was known in 1876, I have no hesitation in holding that Varley's specification sufficiently describes both the shunt and the series-shunt machine. The first sentence in the passage already quoted contains an accurate representation of shunt-winding. The electricity developed by the machine is to be "diverted," which is the word used in the appellants' specification to denote bifurcation, into two parts, one for magnetising, and the "remaining portion" for producing light. These expressions plainly refer to a single current of electricity generated by the machine, which is to be split into two currents, one for excitation of the magnets and one for work, an arrangement which, according to the evidence, embraces all the essential features of a shunt machine. The sentences which follow appear to me to describe the series-shunt with equal accuracy. They commence with the statement that there are several ways of "doing this," that is of obtaining a circuit of excitation and an electric lighting circuit from a single current, by dividing it into two portions. The method preferred is to make both circuits pass round the magnets, that of greater resistance being employed for excitation only, while that of lesser resistance excites the magnets, and also does the work of lighting. The series-shunt is evidently treated as a mere modification of the shunt system; and I think it might be reasonably regarded in that light by the patentee. The alteration in the mechanical arrangement of the apparatus is in itself trivial; and the possibility of thereby obtaining such a constant potential as would, at a future date, suffice for the purpose of incandescent lighting was not present to his mind. There might, as one of the witnesses suggests, still remain room for a patentable improvement upon the series-shunt as described by Varley, consisting in an adjustment which would ensure a high degree of constant potential. No such possibility is indicated either by Varley, or in Brush's patent of 1878.

In the argument addressed to your Lordships, counsel for the appellants laid much stress upon these words occurring in Varley's specification: "The insulated wire composing the helices is connected to the insulated wire surrounding the soft iron magnets of the machine, and is usually inserted in the circuit of greater resistance." They maintained that the necessary result of giving effect to that direction would be to deprive the apparatus contemplated by Varley of all the characteristics of series-shunt-winding. The point does not appear to have been pressed in the Courts below; at least, it was not put before the witnesses, and is not noticed by any of the Judges. In the absence of evidence to support the appellants' contention I have come to the conclusion that the adjustment thus indicated might affect the constancy of the volume of electricity conveyed by the electric light circuit, but that the apparatus would still be a series-shunt-winding machine. These reasons are sufficient to dispose of this appeal, and I desire to express no opinion upon the matter of prior public user. The argument of the appellants satisfied me that the question was one upon which I should prefer not to form any conclusion, without hearing counsel for the respondents. I therefore concur in the judgment which has been moved by the Lord Chancellor.

Lord HERSCHELL said that this is an appeal against interlocutors pronounced in an action of reduction brought by the respondents for the purpose of obtaining the revocation of certain letters patent then vested in the appellants. The letters patent in question bear date the 18th of May, 1878, and claim the invention of "improvements in apparatus for the generation and application of electricity for lighting, plating and other purposes." The original specification concluded with 16 claims, to only two of which I need now refer. The eighth claim is for what is termed in relation to dynamo-electric machinery, the "shunt" system, that is to say, a dynamo-electric machine, wherein a portion of the current produced is diverted for the purpose of maintaining a permanent magnetic field. The ninth claim is for what is now termed the shunt-series system or compound winding. In January, 1882, a disclaimer was filed, by which the eighth claim was abandoned, it having been discovered that the shunt system was not new at the date of the letters patent. The main question, and, indeed, in my opinion, the only question with which your Lordships need concern yourselves, is, whether the shunt-series system was a new invention at that date. It is alleged by the respondents that it was not only communicated to the public by the specification of the letters patent granted to Samuel Alfred Varley in December, 1876, but that a machine was, under his instructions, constructed on that system, and had been in actual use before the date of the patent now vested in the appellants. Varley's specification claimed a method of obtaining a high degree of "magnetic potential" in the bobbins of an electric machine, and the claim had no reference to the manner in which the electricity generated was to be employed, but there occurs in the course of the specification the following passage:—"Part of the electricity developed by the machine is diverted to maintain the magnetism of the soft iron magnets, and the remaining portion is used to produce the electric light. There are several

Digitized by Google

well known ways of doing this, but the method I prefer is to use the soft iron magnets with two insulated wires, one having a larger resistance than the other. The circuit of larger resistance is always closed, and the circuit of less resistance is used for the electric light. When the electric light is being produced, the greater portion of electricity passes through the circuit of less resistance, which I term the 'electric light circuit,' maintaining the magnetism of the magnets, and producing the light. When the electric light circuit is opened from any cause, the electricity passes through the circuit of greater resistance only and maintains the magnetism of the magnets." It is scarcely denied that to any electrician possessed of the knowledge of the present day, these words would convey the idea of the series-shunt system of winding. But it is said, and with truth, that this is not the test, and that the question is what idea they would convey to a person reading them prior to the date of the patent which is in contest in the present suit. The learned counsel for the appellants argued strenuously at the bar that in the light of the more limited information then available, such a reader would not be led to a knowledge of the device described in Brush's patent. They contended, moreover, that in other parts of Varley's specification statements are to be found, which, taken in connection with the passage relied on, would lead the reader away from the conception of this scheme of compound winding. It is necessary, therefore, to inquire what was the state of knowledge prior to 1878. The system of series-winding was well known. By this arrangement the current generated is led round the magnets, and from the magnets is conducted to the lamps, or to serve the other purposes for which it is to be employed, and then back to the machine so as to complete the circuit. This device was subject to the defect that the magnetism of the magnets might be diminished at the very time when it was desirable that the current generated should be maintained. In May, 1876, letters patent were sealed bearing date 11th of December previous, the specification of which, it is admitted, disclosed the shunt system of winding, by which one part of the current is diverted to maintain the magnetism of the soft iron magnets, whilst the remainder is used to produce the electric light, or serve any other purpose for which the current is required. It was urged on behalf of the appellants that there was no evidence that the invention just disclosed had become commonly known prior to 1878, or that it had ever been put in operation, and that Varley's specification ought, therefore, not to be construed on the assumption that those who read it would be acquainted with the shunt system of winding. I cannot accede to this view. It appears certain that at the date when he took out his patent Varley was acquainted with the shunt system, and, indeed, with the shunt-series system of winding, for this is conclusively established by the drawing made by him which was put in evidence. Of course I do not refer to this for the purpose of construing his specification, but only as bearing on the question whether the shunt system was known prior to 1878. The shunt system had been described in Clark's specification of 1875, and it is impossible to say that other electricians may not have been, like Varley, acquainted with it. Under these circumstances I cannot regard it otherwise than as part of the stock of public knowledge, which must be taken into account when approaching the construction of Varley's specification. Taking, then, the shunt system and the series system of winding as both known, what information ought the specification of Varley to be regarded as conveying? The words with which the important passage in Varley's specification commences appear to me to be apt to describe the shunt system. It is impossible not to be struck with the similarity of the language used to that which is to be found in the part of Brush's specification which was avowedly describing that system. I am not much struck with the suggestion that the words "the remaining portion is used to produce the electric light," indicate that the use was to be for that purpose alone, and that this portion of the current was to play no part in maintaining the magnetism of the magnets, and that the description is, therefore, inconsistent with the shunt-series system. It seems to me impossible so to understand the language employed when the import of the sentences which immediately follow is considered. Indeed, it is admitted by one of the defendants' witnesses, Prof. Silvanus Thompson, that the criticism resolves itself into this, that he finds in two sentences what he might have expected to find in one. But a passage such as that with which we are dealing, in which each sentence is obviously connected with those which precede and follow, must be construed as a whole, and such a criticism as that which has been applied to it appears to me wholly inadmissible. Then it is said that, although compound-winding is described, it would not be understood at that time to refer to compound-winding as now understood, but to the winding on the magnets of two wires the current of electricity in each of which was separately excited. But the fact that it is prescribed that one of the two wires is to have a larger resistance than the other, and the statement that when the electric light is being produced "the greater portion of electricity" passes through the circuit of less resistance, appear to me not to suggest the idea of separate excitation, but the contrary; and when the whole passage is read together this impression is strengthened. And it is admitted by defendants' witnesses that there is at least one passage in the specification inconsistent with the idea that separate excitation was contemplated. The argument that other parts of Varley's specification would lead the reader away from the conception of compound winding was mainly founded upon this passage:—"The insulated wire composing the helices is connected to the insulated wire surrounding the soft iron magnets of the machine, and is usually inserted in the circuit of greater resistance." It was argued that if this were done the circuit of greater resistance would not be always closed. This assertion is controverted. But whether it be correct or no, I do not think the words relied on would lead anyone reading the earlier part of the specification to the conclusion that the circuit of greater resistance was not intended to be always closed in face of the express statement that it was to be so. The other criticisms were, to my mind, of less weight, and I do not think that any part of the specification would divert a reader of the important passage on which the controversy has mainly turned from the idea of shunt-series winding. Sir W. Thomson, one of the defendants' witnesses, admits that it is quite probable that in 1876 a workman might have been led to series-shunt winding by Varley's descriptions. And Professor Silvanus Thompson says:—"If a workman of the present day were to read Varley's patent I think he would read it as describing a shunt-series machine, because he would read the knowledge of the present day into it, and that would alter the meaning he attached to the language." Now I admit the difficulty of divesting oneself of existing knowledge, and interpreting any description as it would have been interpreted when the stock of knowledge was more limited. But to anyone acquainted with the shunt and series systems, I think the same idea would be conveyed as is conveyed now. If to a person cognisant of these two systems the conception of their combination into the shunt-series system would have constituted a new departure, the case might have assumed a different complexion; but it is clear that Varley did not regard this combination as a new discovery. And I think it impossible to read Brush's specification without seeing that when once he had arrived at the shunt system, the application of it in conjunction with the series system appeared to follow as a corollary. His object was to secure a permanent magnetic field. He attained this object by means of the shunt system. His words are, "I attain my object by diverting from external work a portion of the current of the machine, and using it either alone or in connection with the rest of the current, for working the field magnets." He treats the shunt-series system, in truth, as a mere modification of the shunt system, of which he believed himself to be the inventor, though he has naturally a distinct claim to cover this modification. The learned counsel for the appellants laid great stress on the fact that, since Brush's specification, the shunt-series system has come largely into use, and deduced from it the argument that it could not previously have been known. But it must be remembered that the importance of this system has only become very marked since the incandescent lamp has come into use. In connection with this form of electric lighting it is no doubt of the highest importance to secure a constant potential. And this object is best attained by the shunt-series system; the defects of each of these systems when used separately tending to counteract one another when they are used in combination. But there is not a trace in Brush's specification of this idea of constant potential. What he was concerned to obtain was a permanent magnetic field. He expresses his preference for the combined systems, "especially for electro-plating machines." It is true that a certain number, not, I think, a very large number, of Brush's machines were introduced into this country for electro-plating purposes before the days of the incandescent lamp. It is, however, regarded as an open question whether pure shunt is not better for the purpose of electro-plating than series-shunt, owing to the possibility that the polarity of the magnets may be reversed. It would seem that whilst the latter system is more in vogue in America, the former is given the preference in this country. I am satisfied that neither Varley nor Brush had in his mind the importance of maintaining a constant potential. But for the reasons I have given I think that any electrician reading Varley's specification with a knowledge of the two systems of series and shunt would have found there a description which he would have had no difficulty in giving practical effect to, of the system of compound winding, known as series shunt. Having arrived at this conclusion it is unnecessary to determine the effect of the use of the machine constructed under Varley's instructions, though I think it would be a matter for serious consideration whether after that use the appellants' patent could be supported. I think the judgment of the Court below was right, and ought to be affirmed.

LORDS MACNAGHTEN and FIELD also concurred.

The appeal was accordingly dismissed with costs.

Dovey v. Pixley.

In the Queen's Bench Division on Saturday, before Mr. Justice A. L. Smith, the action of Dovey v. Pixley was tried. It was an action brought by the owner of house property at the Albert Embankment, Princes-street, Lambeth, against the liquidator of the Electrical Engineering Corporation (Limited) to recover between £200 and £300 in respect of damage alleged to have been done to premises the Corporation held under lease for the purposes of their business. The defendant denied personal liability. The plaintiff leased the premises to the Corporation in October, 1882. In March, 1891, the debenture holders sued the Corporation to get their rights ascertained as to what charge they had upon the Company's property. Mr. Justice North appointed the defendant receiver and manager in the action, and in April the Corporation passed a resolution for voluntary winding up under the supervision of the Court, the defendant being appointed voluntary liquidator. Mr. Justice Kekewich subsequently ordered a sale on the premises, which took place in July, and it was in connection with the sale and the removal of machinery that the damage was said to have been done.

Mr. COHEN submitted, on behalf of the defendant, that property did not vest in a liquidator, and that unless the plaintiff could prove that the defendant, as manager, did something he had not been directed by the Court to do there was no cause of action.

In the result,

Mr. JUSTICE SMITH said that no doubt the plaintiff had suffered, and if the plaintiff had got the right paymaster in Court he should have awarded him damages, but he had not. If the Corporation had been worth anything he had still his remedy and could prove for his claim; but having got an insolvent tenant he could not go against a man who never was tenant at all. He could not do so on the ground of covenant, nor on the ground of breach of duty or of tort. The defendant's answer was the order of the Court. His (the learned Judge's) opinion was that what the

Digitized by Google

defendant did he did as receiver and manager, and not as voluntary liquidator; but it did not make much difference in which capacity he acted. It was said the defendant had been guilty of excess in allowing the premises to be torn about in a way he ought not to have done. The evidence was conclusive that the premises had been damaged, and Mr. Dovey had suffered; but he had sued the wrong defendant, and could not put his hand in Mr. Pixley's pocket.

Judgment for the defendant, with costs.

Re City of London Electric Lighting Company.

A sitting of the Consistory Court of London was held on Wednesday in St. Paul's Cathedral, before Dr. Tristram, Q.C., Chancellor of the Diocese of London, to consider petitions by the rector and churchwardens of the parishes of St. Bene't Sherehog and St. Nicholas Acons for faculties authorising them to grant small portions of the churchyards to the City of London Electric Lighting Company for the purpose of giving access to vaults to be constructed by the Company under the public footway in Pancras-lane and Nicholas-lane, adjoining the churchyards.

The CHANCELLOR OF LONDON, in giving judgment, said:—There is no precedent for the granting of a faculty under the circumstances mentioned in the two cases now before the Court. The present applications are made by the rectors of the two parishes, with the sanction of the parish vestries, but at the instance of the City of London Electric Lighting Company, for leave to construct a flight of steps, with an entrance thereto, underneath the edge of each of the churchyards, with the exclusive user of such steps, in order to give the Company access to chambers which it proposes to construct underneath the narrow street abutting on each churchyard, for the storage of an apparatus for converting electricity. If the Court has jurisdiction to grant a faculty to give the user of a way across a churchyard, it must equally have jurisdiction to grant the user of a way underneath a portion of a churchyard. The Court being of opinion that it is within its discretionary jurisdiction to grant a faculty for erecting the flight of steps underneath the churchyard, with an entrance thereto, for the object named, it remains for it to consider whether from the facts proved it ought to exercise such discretion in the present cases. I have had the advantage of inspecting these churchyards, accompanied by Major-General Webber, the chief engineer of the Company; and it occurred to me during the inspection, as it is proved by evidence, that unless the faculties are granted, the Company would be unable to introduce electric lights into the offices of this part of the City unless it were to construct entrances in the narrow streets, which Major-General Webber says in his evidence would be an intolerable inconvenience to the public, or unless it were by purchase to procure a right of entry to the chambers from one of the opposite houses, and this it might be unable to do without a private Act of Parliament. It is clearly, therefore, for the convenience of the parishioners that the faculties should be granted. With regard to the payment of £5 a year proposed to be made by the Company in respect of St. Bene't Sherehog, the rector is prepared to assent to the payment being expended in keeping the churchyard in order. With regard to the voluntary payment proposed to be made to the churchwardens of St. Nicholas Acons, as the rector consents to the sum of £20 a year being paid as a contribution by the Company to a church fund for keeping up the church and churchyard, the Court will by the faculty sanction such payment. The Court decrees the faculties, subject to the terms mentioned.

Woodhouse and Rawson United (Limited) v. Alexander, Wright & Co.

In the City of London Court on Friday last, before Mr. Commissioner Kerr, Messrs. Woodhouse and Rawson United (Limited) sought to recover a debt due from the defendants, Messrs. Alexander, Wright and Co., Millbank-street, Westminster. The claim was not in dispute, but the defendants raised a counter claim for goods supplied to the plaintiff Company.

Mr. W. HICKS, for the plaintiffs, said the counter claim should have been brought against the Woodhouse and Rawson Electric Supply Company of Great Britain, and not against the plaintiffs, who were a distinct Company altogether. The "United" Company was not connected in any way with the Electric Supply Company, which was in liquidation.

The DEFENDANT said there were a great many Woodhouse and Rawson Companies, and he believed they were all one and the same.

Mr. COMMISSIONER KERR said no doubt the plaintiff Company was practically the same as the other one mentioned.

Mr. HICKS repeated his assurance that the Companies were quite distinct.

Mr. COMMISSIONER KERR said he should find for the defendant beyond the money paid into court, disallowing any costs.

CORRESPONDENCE.

THE GENERAL ELECTRIC POWER AND TRACTION COMPANY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has been drawn to a paragraph respecting this Company in your last issue. The statement that the Kentish Town Works have been closed is not quite accurate, and is certainly premature. The arrangement as it stands at present is merely a reduction of unnecessary working expenses, and will, no doubt, enable my Company to occupy a stronger position than ever.

The whole management of the Company has been changed, and I may take this opportunity of saying that the other departments of the Company's operations, especially the electric launch business, are in an exceedingly prosperous condition.

Trusting you will kindly insert this correction, as the paragraph in your last issue was somewhat misleading, I am, &c.,

THE GENERAL ELECTRIC POWER AND TRACTION COMPANY (LIMITED),

April 7, 1892. T. SMITH, Secretary.

[The note in question was not inserted without due inquiry and confirmation, but we regret that we omitted to obtain fuller corroboration from the Secretary of the Company.—ED. *E.*]

THE ROUNDHAY ELECTRIC TRAMWAY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of April 1st you seem to have misunderstood my statements at the discussion upon Mr. Reckenzaun's Paper before the Institution of Electrical Engineers, and in your "Notes" upon same you are open to corrections, viz.:—

The difficulty in obtaining men to look after and run the motors is very real, and it is only to be expected, when it is remembered how small is the field in this country for men to obtain even a very rudimentary knowledge of traction motors and their handling. We have had to train, *ab initio*, some twelve to eighteen men for drivers. The details, electrical and mechanical, of our system have given the most perfect satisfaction here, as they have heretofore in the States. My point at the discussion was that this being the first Thomson-Houston road in operation under English conditions, physical and atmospherical, necessitated the greatest care and attention in the observation of details of working, so as to enable us to perfect in every possible way the adaptation of such details to the new conditions, which in many points differ materially from our American work. To do this involves the employment of a larger and more expensive staff than would be needed for pure commercial working. Hence a large general expense account.

The cost I quoted of 6.63d. per car mile includes *everything* in connection with the operating and general expense of the road; and this sum will be materially reduced when we have some weeks of fair weather to average the very hard winter which has held throughout Yorkshire. If I am not mistaken the figures you quote for accumulator cost of traction are *paper figures* and were largely exceeded in practice. These four and a-half pennies did not include anything more than cost and maintenance of power and drivers; when my costs are made to only include these items the comparison puts the overhead system in this country in the same position *re* costs that it holds in other countries, *i.e.*, far in front of all competitors.

This figure, speaking without the book, is on our road under 3·80d. for cost of power, maintenance, and drivers; and please to remember this is from actual working, and is not an empirical cost for the purpose of business.

I trust that my few explanations contained herein will serve to show more clearly the actual facts about Leeds; and apologising for occupying so much of your valuable space, I beg to remain, yours, &c., W. S. GRAFF BAKER.

Leeds, April 4, 1892.

[The remarks in our Notes were chiefly directed to the necessity, to which Mr. Baker merely alludes, for the adaptation of the details to the new conditions. These, he says, differ materially in many points from American work. His "few explanations" do not touch on these differences and new conditions. We should be glad to hear, at least, what they are.—ED. *E.*]

OIL AS AN INSULATOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the authorised abstract which appeared in your journal of the discussion on Prof. Hughes's Paper, I notice that I am credited with saying that the resistance of certain oils varies 20 per cent. between 16° and 24° C. This should read "between 16° and 18° C."

I should be much obliged by your inserting this correction in the next issue of your journal.—Yours, &c.,

H. CUTHBERT HALL.

52, Queen Victoria-street, London, E.C.,
April 1, 1892.

LORD ARMSTRONG'S MAINS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the Note contained in your issue for the 25th inst., with regard to the outdoor mains that Messrs. Drake and Gorham are putting into the installation that they are erecting for the Duke of Montrose, it appears to me only fair that it should be mentioned that this system of mains, which, as it seems, is being copied from that that has been in successful operation at Lord Armstrong's for some years past, was not originally introduced by Messrs. Drake and Gorham, but was designed in its entirety by Lord Armstrong and myself, and was erected by Lord Armstrong's own estate workmen.

The system is of some interest, as it forms, probably, the first practical example of the arrangement of bare conductors laid on insulating blocks, since so widely employed for low-tension distribution from central stations.—Yours, &c.,

A. A. C. SWINTON.

66, Victoria-street, London, S.W.,
March 28, 1892.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892.

The tenth annual edition of the above well-known annual is now ready, price 7s. 6d.; post free, in the United Kingdom, 8s 3d.; abroad (with the exception of a few countries), post free, 8s. 10d.

The edition consists of between 900 and 1,000 pages, and special care has been taken to make the Directorial division of the book, which has been considerably extended, thoroughly accurate and reliable. In this respect no possible comparison can be made with any similar publication.

To the Handbook division has been added several features which will be found of service to the Electrical and Allied Trades. The Digest of the Law of Electric Lighting has been thoroughly revised and brought up to date, and the most recent Board of Trade Regulations are also included. The various tables and tabulated statements have been remodelled and amplified; and a new feature is the tabulation of valuable information respecting Electrical Limited Liability Concerns.

An important feature is the space devoted to the officials of Foreign and Colonial Governments who have the superintendence of contracts and the giving of orders for electrical plant and apparatus; and as this has been kindly supplied by the various Government departments, it can be relied upon, as can also the particulars given respecting the Home Government departments.

The profession will find "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK a trustworthy work of reference, and purchasers of plant and apparatus may confidently turn to its pages for the names of all the principal firms supplying their requirements. Nearly every firm of any standing in the Electrical and Allied Trades is represented in its advertisement pages.

A digest of the contents of the book will be sent on application.

VACANT APPOINTMENT.—An engineer is wanted, accustomed to the erection of land lines. The appointment is for Argentina and Chili. Further particulars are given in our advertising columns.

THE LANE FOX PATENTS.—It is announced, by Messrs. Vandercom and Co., solicitors, that application will be made to Her Majesty in Council praying that the letters patent of Mr. Lane Fox for improvements "in distributing and regulating the electric current or obtaining light by electricity and in the means or apparatus employed therein," may be extended for a further term, and that on May 9th next (or thereabouts) application will be made to the Judicial Committee of the Privy Council for the hearing of the said petition.

REMOVAL NOTICES.—Messrs. Wheatley Kirk, Price, and Goulty notify us that they have removed from 52, Queen Victoria-street to 49, Queen Victoria-street (Albert-buildings), immediately opposite the Mansion House Railway Station, to which new address all future communications are to be sent.

——— Mr. R. G. Ivey has removed from Chatham-place, Hackney, to larger premises at 7, Portpool-lane, Gray's Inn-road, W.C.

MESSRS. POOLE AND WHITE (LIMITED).—This firm have just opened a branch office at 27, Arcade-chambers, St. Mary's Gate, Manchester, under the management of Mr. T. A. Nunwick, representative of the firm for the North of England.

INCANDESCENT LAMP PRICES.—The Edison and Swan Company notify special discounts on incandescent lamps to the trade, as dating from April 1st. These discounts are subject to certain conditions, particulars of which will be found in our advertisement pages.

MESSRS. FRITSCHE AND PISCHON.—We have received a notification that Herr C. H. Pischon has ceased to be a member of this firm.

CROMPTON-HOWELL BATTERIES.—We are in receipt of the newly issued illustrated catalogue and list of prices of the Crompton-Howell Electrical Storage Company (Limited). Several types of battery are illustrated in the catalogue, and a list of the installations is given in which the batteries are used.

NEW EDITION.—Messrs. Whittaker will shortly issue a fifth edition of Mr. Bottone's work on "Electrical Instrument Making," revised, and with additional chapters.

THE ENGINEERING EXCHANGE FOR LONDON.—A meeting to inaugurate the above was held on Wednesday last in the Cannon-street Hotel, Mr. Reginald Bolton occupying the chair. Resolutions were passed giving effect to the draft scheme, which we published last week; and a provisional committee, consisting of Messrs. R. Bolton, Tyler, Potter, Frederick Rawson, Hargreaves, Henriques, and Devicien was named, to take steps to form and open the Exchange immediately. We understand that this committee will for the present co-operate with and share the premises of the Jerusalem Shipping Exchange.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

March 8, 1892.

4,523. THE RIES ELECTRIC SPECIALITY COMPANY. London. Regulating sockets or holders for incandescent electric lamps and other translating devices.

4,543. G. WILSON. Aberdare. Electrical measuring instruments.

4,576. J. V. SHERRIN. London. Improvements in secondary batteries.

4,578. A. C. CAREY. London. Improvements in and relating to applying carbon filaments to electric lamps.

4,579. S. A. ROSENTHAL and J. V. SHERRIN. London. Improvements in galvanic batteries and battery liquids.

4,586. C. T. THOMPSON and R. H. SANDERS. London. Improvements in magnetic separators for ore and similar material.

4,610. G. F. PINKHAM. London. Improvements in electric gas-lighting burners.

4,617. F. A. FELDKAMP, J. SCHOENHAAR, and E. E. LEHR. London. Improvements in electrical attachments for pianos.

March 9, 1892.

4,691. E. SCHWEIZER. London. Improvements in secondary electric clocks.

4,709. R. F. YORKE. London. An improved method of and means for electric wiring.

March 10, 1892.

4,758. W. BOGGETT. London. Improvements in the methods and means of obtaining electricity.

4,764. H. H. LAKE. London. Improvements in insulators for electric wires. (C. N. Hammond, United States.)

4,768. S. W. MAQUAY. London. Improvements in electric batteries.

4,773. G. F. REDFERN. London. Improvements in the manufacture of electrical conductors. (S. Bergmann, Germany.)

Digitized by Google

4,779. J. J. Rathbone and J. Houghton. London. An improvement connected with electric arc lamps.

March 11, 1892.

4,816. W. Fairweather. Glasgow. Improvements in electrical cables. (E. F. Phillips, United States.)

4,820. L. Mercky. London. Improvements in primary batteries.

4,841. W. L. Spence. Manchester. Improvements in the methods of driving electric railway trains.

March 12, 1892.

4,883. W. F. Taylor. Croydon. Improvements in methods of alternating current distribution.

4,930. P. Manchin. London. Improvements in and relating to fusible cut-outs.

March 14, 1892.

4,949. A. F. Willman. London. The generation of electricity for electric lighting and other purposes.

4,955. C. S. Bedford. Leeds. Improvements in the manufacture of insulating materials.

4,961. A. Muirhead. London. Improvements in slide resistances for electrical purposes.

4,988. C. E. Thomson. London. Improvements in electric-circuit closers.

4,992. H. Edmunds. London. Improvements in insulated electric conductors and means to be employed in their production.

5,002. G. Wilkinson. London. Improvements in electrical conductors and means for laying the same.

March 15, 1892.

5,052. G. Davis. London. Electrically driven whipper for eggs, creams, sauces, and the like.

5,085. W. P. Hall. London. Improvements in electric block signalling apparatus.

5,096. E. J. Silkman. London. Printing telegraphs.

March 16, 1892.

5,130. G. G. Crosby and Don C. A. Thatcher. London. Improvements in magnetic ore separators.

5,141. C. S. Snell and Woodhouse and Rawson United (Limited). London. Multiple fuses and switch for use in electric circuits.

5,161. J. S. Vost and F. R. Fisher. Halifax. An improved telephone cabinet.

5,186. L. Lenczewski. London. Improvements in electric arc lamps.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1890.

20,992. Jones. Electric bells.

1891.

2,040. Müller. Secondary batteries.

2,471. Bush and Doubleday. Electrical batteries.

4,064. Hookham. Electricity meters.

4,306. Boggett. Dynamo-electric generators.

4,740. Attree. Electric signalling for railways.

5,167. Elmore, F. E. and A. S. Making tubes by electrolysis.

5,342. Callendar. Electrical thermometers.

5,947. Chapman. Incandescent electric lamps.

6,517. Dorman and Smith. Electric light switches.

6,660. De Ferranti. Distributing electrical energy.

6,978. Boult. (Stone.) Dynamo-electric machines.

7,075. Royce. Electric lamp holders, &c.

7,283. Bennett. Telegraphy and telephony.

7,331. Abel (Société Générale des Téléphones). Telephonic apparatus.

7,430. Heaviside and Others. Driving dynamo-electric machines.

7,433. Solomons. Testing electric lightning conductors, &c.

7,518. Bullock and Brown. Telegraph instrument.

7,531. Cuthbert. Tools for electric linemen.

7,697. Elieson. Storage batteries.

7,728. Lea. Electric lamp-posts.

8,048. Kennedy. Dynamo-electric generators.

8,151. Siemens Bros. and Co. (Limited) (Siemens and Halske.) Distributing alternating currents.

8,227. Thompson. (Tudor.) Electric accumulators.

8,845. Haddan. (Cabanyes.) Galvanic batterie .

10,451. Haywood and Driver. Electric light, &c., posts.

16,958. Mavor and Others. Electric lighting, &c. conductors.

19,968. Burt. Electric motors, &c.

1892.

1,391. London Metallurgical Co. (Limited) and Cowper Coles. Coating articles by electro-deposition.

1,396. Eichler. Electric circuit-breaker.

1,484. Entz and Phillips. Secondary batteries.

1,580. Mathews. Electric low-water alarm.

2,016. Price. Conduits for electrical cables, &c.

2,026. Lake. (Grissinger and another). Electrical telephones.

2,290. Ries. Electric riveting.

COMPANIES' MEETINGS.

House to House Electric Light Supply Company (Limited).

The fourth ordinary general meeting of this Company was held at the Company's Central Station, Richmond-road, Kensington, on Tuesday last, under the presidency of Mr. Henry Ramié Beeton.

The SECRETARY (Mr. H. St. John Winkworth) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen—The report and accounts set out, of course, most of the facts connected with the progress of the Company for the year 1891, and I think that the shareholders will probably agree with me that the result is comparatively satisfactory. It will be seen that the capital expenditure for the twelve months has amounted to £8,996, and that the increased revenue is upwards of £3,300, which has been earned at a percentage of working expenses of 41 per cent., thereby reducing the percentage of expenses from 92 per cent. in 1890 to 79 per cent. in 1891. The profits would have been much larger if the rate of progress during the year had been equal to that of the preceding year. Unfortunately, it has not been quite maintained. On December 31, 1889, there were connected with the Company's mains 4,520 35-watt lamps, and on December 31, 1890, there were connected 13,665 of the same lamps, showing an increase during the year of 9,145. On December 31, 1891, there were connected with their mains 19,388 35-watt lamps, showing an increase during the year of 5,723. Since the close of the year 871 had been added, raising the total connected on March 31st to 20,259, and there is every indication from the orders in hand and the general development of the district that we shall have a satisfactory increase during the year. The Company has, of course, benefited by the administrative economies which I referred to at the last general meeting as being on the point of being introduced. In addition to that it has been benefited by improvements in the works, which have been effected as the result of greater experience and more perfect organisation. The condition of things which these facts disclose will, I think, justify the assumption that any future increments of capital are likely to be employed at a high rate of productivity, and that after the claims of such capital have been satisfied there wi l be left a surplus which will go to the ordinary shareholders. At our last general meeting I was able to announce that the negotiations which had been for some time on foot for the benefit of our construction asset were on the point of being concluded; and although their consummation was delayed longer than I anticipated at the time, I am pleased to say that we have at length participated in a contract with the Leeds and London Electrical Engineering Company, whereby our Company, although it will not enjoy a large share of the profits of that undertaking, will not, on the other hand, be called upon to provide any funds, or take any further risk. Moreover, we are guaranteed £525 a year for two years, and if the business is as successful as it promises to be we may get more than this for many years. With these few remarks I beg to move that the report and accounts be adopted.

The MANAGING DIRECTOR (Mr. Robert Hammond) in seconding the motion, thought that the shareholders would be interested to know that the rate of increase of their business during the year would have been much larger if the Company's plant had permitted its engineers to take on more orders. They had been somewhat deficient in point of plant, and the active canvassing for business which went on in the previous year had not been continued in 1891. They might therefore fairly say that in the coming year, when further plant would be added to the station, they would have a considerable number of lights added to their circuit. Since the accounts were closed more preference capital had been issued, and freely taken up, amounting to £12,290, which would enable the Directors to spend more money in the works, thereby increasing their output. He thought that the Chairman was justified in alluding to the favourable prospects of the Company. Their business had been gradually increasing, and the Directors were not taking too sanguine a view in forecasting the future. They had reached that point of the Company's history when they were getting on a dividend-paying basis, a circumstance on which he heartily congratulated the shareholders. It might be known to them that the Leeds and London Electrical Engineering Company was formed for the purpose of dealing efficiently with the so-called construction asset of the House to House Electric Light Supply Company, it being felt that the latter should devote its energies to the supply of electricity from house to house, leaving to another company the manufacture of machinery and the erection of stations. An agreement on these lines had been made with the Leeds and London Company, of which he was a Director, and he was pleased to say that a notice appeared in a morning paper of the preceding day to the effect that at the meeting of the Burton-on-Trent Corporation, on Wednesday, the electric lighting committee were to recommend that the contract for the central station at Burton-on-Trent should be given to the Leeds and London Company, on whose profits they had a large charge, so that the £525 alluded to by the Chairman might this year be £1,050, if not more. He was glad to inform the shareholders that the Yorkshire House to House Electricity Supply Company, which brought grist to the mill of the Leeds and London Company, had had a certain amount of capital subscribed, which would result in a profit to that Company, with which they were practically affiliated. He concluded by saying that the light supplied by the Company met with general approval, and no company more satisfactorily fulfilled its obligations to its customers than did theirs.

In reply to Mr. ARTHUR KIMBER,

Mr. HAMMOND added that the accounts were made up in the form prescribed by the Board of Trade.

The motion was carried unanimously.

Digitized by Google

The CHAIRMAN proposed, and Mr. DAVIES seconded, the declaration of a dividend at the rate of 7 per cent. on the preference shares.

The motion having been agreed to,

Mr. HAMMOND moved, and Mr. WM. PAGE seconded, the re-election of Mr. Beeton to his seat at the Board.

The motion was agreed to *nem. con.*

The CHAIRMAN proposed, and Mr. W. F. LEESE seconded, the re-election of Mr. Hammond to his seat at the Board, which was also carried unanimously.

The CHAIRMAN next proposed the election of Mr. Leese as a Director.

Mr. JAMES WHITEHEAD seconded the motion, which was carried.

The CHAIRMAN explained that Mr. Joaquin de Galindez had been obliged to go abroad, and did not, therefore, offer himself for re-election. The other election to the Board was that of Mr. Reginald Davies, whose services had been and would be very beneficial to the Company, and he had much pleasure in proposing it.

Mr. HAMMOND seconded the motion, which was carried unanimously.

Mr. KIMBER proposed, and Mr. WHITEHEAD seconded, the re-appointment of the auditors, Messrs. Theobald Bros. and Miall.

The motion having been agreed to, Mr. HAMMOND proposed and a SHAREHOLDER seconded a vote of thanks to the Chairman, who briefly returned thanks, and the proceedings terminated.

The Telephone Company of Egypt (Limited).

The ninth ordinary annual general meeting of this Company was held on Tuesday at the offices of the Company, 14, Austin Friars, under the presidency of General Alexander Fraser, C.B., R.E.

The SECRETARY (Mr. Alexander B. Chalmers) read the notice calling the meeting; and the Directors' report and statement of accounts were taken as read.

The CHAIRMAN said he had very little to say beyond what was contained in the report circulated among the shareholders. The business generally had continued in an even course during the past year, and they were glad to be able to propose the usual dividend of 6 per cent. on the Preferred shares. The business, he said, was one he did not think would further improve by leaps and bounds: but they might hope that under the good management of their staff in Egypt there would always be a small annual increase in the number of their subscribers taken as a whole. It was true that that increase was sometimes discounted by a demand for lower rates, a demand, however, they had been forced to resist when they thought that the rates were as low as an efficient service would permit. It was an efficient service, and they were, he thought, justified in considering it so in the absence of complaint. Their manager in Egypt was a very good officer of the Company, and with the careful supervision of his accounts by the Secretary and his staff, the Board was enabled to keep the cost of the service at the lowest possible point consistent with efficiency. He concluded by formally proposing—

"*That the report and accounts for the year ended 31st December, 1891, be and are hereby approved and adopted, and that a dividend be paid of 6 per cent. on the Preference shares, free of Income Tax.*"

Mr. THOS. LLOYD seconded the motion, which was carried unanimously.

Mr. GREWING next moved—

"*That General Alexander Fraser, C.B., R.E., be and he is hereby re-elected a Director of the Company.*"

Mr. LLOYD seconded the motion, which was also carried unanimously.

On the motion of Mr. ADDISON seconded by Mr. HENTSCH, the auditors of the Company, Messrs. Price, Waterhouse, and Co., were re-appointed. Mr. ADDISON also moved a vote of thanks to Mr. Evans and the staff in Egypt, which was carried unanimously.

A further vote of thanks to the Chairman for presiding terminated the proceedings.

The Electric Construction Corporation (Limited).

An extraordinary general meeting of the shareholders of this Company was held at Worcester House, Walbrook, on Thursday, the 7th day of April, for the purpose of considering, and, if thought fit, confirming as special resolutions, the resolutions which were duly passed at a general meeting, held at the same place, on the 22nd day of March, 1892; Mr. J. Spencer Balfour, M.P., presided.

Mr. W. SAMSON (the Secretary) having read the notice calling the meeting, and the resolution to be confirmed,

The CHAIRMAN said: Gentlemen, you have heard the resolution read, and the subject matter of the resolution has been considered by no less than three general meetings of this Corporation, and at each of these meetings the resolution has been unanimously approved. I assume you will not, therefore, wish me to occupy your time now in moving, as I do—

"*That the resolution which was duly passed at the meeting held on the 22nd of March, 1892, be, and the same is hereby, confirmed as a special resolution, viz.:—'1. That one-half of the said new shares, being those numbered 62,501 to 75,000 inclusive, be allotted and issued by the Directors to such persons and at such times as the Directors shall think proper, and that the said shares shall be Preference shares, and shall entitle the holders thereof to a cumulative dividend at the rate of 7 per cent. per annum upon the amount credited as paid up thereon, in priority to any dividend on the Ordinary and Founders' shares of the Company. 2. That the said Preference shares shall also entitle the holders thereof, upon a return of capital of the Company, to be repaid the amounts credited as paid thereon, before any payment in respect of capital is made on the Ordinary and Founders' shares of the Company.'*"

I beg to move that resolution.

Mr. J. IRVING COURTENAY (Deputy-Chairman) seconded the resolution.

No questions were asked, and the resolution was put and carried unanimously.

A vote of thanks to the Chairman closed the meeting.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

CHELMSFORD ELECTRIC LIGHTING COMPANY (LIMITED).—This Company was registered on March 30th, with a capital of £10,000, divided into 7,500 preferred and 2,500 ordinary shares of £1 each, by E. H. F. Reeves, Little Heath, Potters Bar. The objects are to enter into and carry into effect, with such modifications (if any) as may be agreed upon, the draft contract already prepared in the name of this Company, and made with Messrs. Crompton and Co. (Limited), for the purchase and transfer to this Company of the Board of Trade licence to supply electricity in the borough of Chelmsford, Essex, and of the electrical installation and agreements in connection therewith; to carry on the business of electricians, mechanical engineers, and manufacturers, and workers of and dealers in electricity, motive power and light; to carry on the business of manufacturers of and dealers in machines, lamps, lanterns, safety lamps, and other appliances for supplying light and power by means of electricity; and to acquire the right to use and put up telephones, telegraphs, phonographs, &c. The signatories to the Memorandum and Articles of Association are:—

	Shares.
John F. Albright, Arc Works, Chelmsford, engineer	1
Carleton F. Tufnell, Lloyd's, E.C., underwriter	1
Hugh G. W. Drummond, 7, Ovington-square, S.W.	1
James Luckin, Chelmsford, chartered accountant	1
James S. Brown, Chelmsford, merchant	1
John P. Bond, Chelmsford, draper	1
Garrard Baker, Chelmsford	1

The number of Directors is not to be less than three nor more than five, the first to be nominated by the subscribers to the Memorandum of Association. For the rest, the regulations of Table A mainly apply.

HICKS, HARGREAVES, AND CO. (LIMITED).—This Company was registered on March 29, 1892, with a capital of £240,000, in £10 shares, by Rowcliffes, Rawle, and Co., 1, Bedford-row, W.C. The objects are to acquire the goodwill of the business carried on by John Henry Hargreaves, Francis Hargreaves, and Percy Hargreaves, under the style or firm of "Hicks, Hargreaves, and Co.," at the Soho Iron Works and the Phœnix Boiler Works, Bolton, and to carry on the businesses of iron-founders, engineers, boiler makers, and millwrights.

MADRAS ELECTRIC TRAMWAYS COMPANY (LIMITED).—This Company was registered on April 2, 1892, with a capital of £100,000, in 100,000 ordinary shares of £1 each, by Paul E. Vanderpump and Eve, 5, Philpot-lane, London, E.C. The objects are to acquire a concession which was granted by the municipal authorities of Madras for the construction of tramways in Madras, and with that object to adopt and carry into effect an agreement dated March 16, 1892, between William Digby and Sidney A. Chalk of the one part, and Frederick W. Fowler, on behalf of this Company, of the other part; to carry out the construction of the said tramways, and when so constructed to work the same either with electricity conveyed through overhead or underground wires, animal power, steam, or other mechanical power, and to carry on the business of tramway proprietors, electrical engineers and manufacturers, electric light engineers, and businesses analogous thereto. The subscribers are:—

	Shares.
W. Digby, 1, Trafalgar-buildings, Northumberland-avenue, S.W., merchant	1
Alfred J. Lustay, 70, Gracechurch-street, E.C., colliery proprietor	1
S. A. Chalk, 1, Trafalgar-buildings, Northumberland-avenue, S.W., merchant	1
A. E. Asser, Suffolk Lodge, Teddington	1
M. M. Bhownaggree, Tessville, Priory-road, Bedford Park, barrister-at-law	1
W. A. Gibson, 4, Queen Victoria-street, E.C.	1
Henry E. Eve, 5, Philpot-lane, London, E.C., solicitor	1

The number of the Directors is not to be less than three nor more than six, the first Chairman being W. Digby and S. A. Chalk, Managing Director

R. BARRETT AND SON (LIMITED).—This Company was registered on March 30, 1892, with a capital of £100,000, divided into 25,000 preference and 75,000 ordinary shares of £1 each, by Burn and Berridge, 11, Old Broad-street, E.C. The objects are to acquire the goodwill of the business of R. Barrett and Son, engineers, iron and brass founders, and manufacturers of automatic machines, and to carry on the business of iron and brass founders, engineers, manufacturers of automatic and other machinery, tool makers, metal workers, boiler makers, machinists, iron and steel converters, smiths, metallurgists, and electrical engineers. Registered office: King's Head-court, Beech-street, Barbican, London, E.C.

BICESTER ELECTRICITY SUPPLY COMPANY (LIMITED).—The statutory return of the above-named Company, made up to March 16, 1892, was filed on March 30, 1892. The Company was registered on November 2, 1891, with a capital of £5,000, in £5 shares; and, at the time of making up, 131 shares were taken up, 10s. called on each, and all calls (£65. 10s.) paid. Of the shareholders, 25 out of the 28 reside or trade in Bicester. No agreements for the purchase of any contracts, plant, businesses, &c., have been filed.

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—The following notice was filed on April 1, 1892:—At an extraordinary general meeting of the Electric Construction Corporation (Limited) duly convened and held at Worcester House, Walbrook, in the City of London, on Thursday, March 3, 1892, the following resolution was duly passed; and at a subsequent extraordinary general meeting of the Company, also duly convened and held at the same place on Thursday, March 22, 1892, the following resolution was duly confirmed as a special resolution:—"That the capital of the Company be increased to £750,000 by the creation of 25,000 new shares of £10 each, numbered 50,001 to 75,000 inclusive."

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of the above named Company, made up to March 24, 1892, was filed on March 30th following. The Company was registered on March 29, 1888, with a capital of £250,000, in £5 shares. The capital is now £350,000, divided into 50,000 ordinary, 10,000 first preference, and 10,000 second preference shares of £5 each. At the time of making up, 15,000 ordinary and 10,000 first preference shares have been taken up, of which 5,000 ordinary shares have been issued as fully paid. Upon the remaining 10,000 ordinary and 10,000 preference shares, the full amounts have been called, and all calls (£100,000) paid. Among shareholders holding more than 500 shares are Sir Richard E. Webster, of 2, Pump-court, Temple, E.C. (1,600).

NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of the above-named Company, made up to February 8, 1892, was filed on the following day. The Company was registered on January 8, 1889, with a capital of £50,000, in £5 shares, with objects as fully indicated by the title. At the time of making up 5,106 out of the 10,000 shares were taken up, of which 18 had been issued as fully paid. Upon 4,066 of the remainder £4 per share had been called, and upon the remaining 1,022 shares £3 per share had been called, resulting in the payment of £20,602 (including £1,572 paid in anticipation of calls), and leaving £300 in arrears.

PONTYPRIDD ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of the above-named Company, made up to March 16, 1891, was filed on March 4, 1892. The Company was registered on April 30, 1889, with a capital of £10,000 in £5 shares. At the time of making up seven shares were taken up, upon which no calls had been made, the original signatories being the only shareholders. No agreements of any kind have been filed.

SOUTH-WESTERN DISTRICT AND THAMES VALLEY ELECTRICITY SUPPLY COMPANY (LIMITED).—The annual return of the above-named Company, made up to December 31, 1891, was filed on March 14, 1892. The Company was registered on June 28, 1889, with a capital of £100,000, in £10 shares. At the time of making up seven shares had been taken up, upon which, however, no calls had been made. A note in the "Remarks" column of the return states that "nothing has yet been done in this Company beyond registering the name and paying the registration fees; but it is intended to begin work next autumn. The stagnation has been due to the enforced absence of myself abroad since November, 1890, until quite lately. (Signed) Daniel de Castro (Chairman)."

THORNEBURRY MINERS' SAFETY LAMP COMPANY (LIMITED).—The annual return of the above-named Company, made up to March 8, 1892, was filed on March 14th following. The Company was registered on May 5, 1890, with a capital of £50,000, in £1 shares, to carry on business as manufacturers of safety lamps, electrical and mechanical engineers, &c. At the time of making up, 30,057 shares had been taken up, of which 20,540 had been issued as fully paid. Upon the remaining 9,517 shares the full amount had been called, resulting in the payment of £8,976, and leaving £541 in arrears. The return for 1891, made up to December 31, 1891, was filed on March 16, 1892, when the same number of shares were taken up, and the same number issued as fully paid. The calls paid then amounted to £7,704. 5s., leaving £1,812. 15s. unpaid.

VAUGHAN-SHERRIN ELECTRICAL ENGINEERING COMPANY (LIMITED).—An agreement made March 9, 1892 (and filed on the 15th following), between S. A. Rosenthal, of 6, Christopher-street, Finsbury, E.C. (the vendor), of the one part, and the Company of the other part, states that whereas by an assignment dated March 25, 1891, between the same parties, the vendor assigned to the Company an invention consisting of a method of turning acid fluids and acid mixtures into a jelly or paste, and all improvements therein, in consideration of a sum of £250 in cash, and the allotment of 250 fully paid-up ordinary shares of £5 each. The present agreement determined that on March 17, 1892, the Company should allot to the vendor or his nominee 250 fully paid-up ordinary shares of £5 each, to be numbered 1,548 to 1,797 inclusive. The annual return of the Company, made up to February 14, 1892, was filed on March 21st following. The Company was registered on August 16, 1890, with a capital of £25,000, divided into 4,975 ordinary shares, and 25 Founders' shares of £5 each. At the time of making-up, 4,034 ordinary and 25 Founders' shares had been taken up, of which 2,487 ordinary and nine Founders' shares had £2. 10s. considered as paid on each. Upon the remaining 1,547 ordinary and the 16 Founders' shares £4 per share had been called, and the calls paid amount to £5,766, leaving £486 unpaid.

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).—The annual return of this Corporation, made up to March 9, 1892, was filed on March 28, following. The Company was registered on June 30, 1888, with a capital of £100,000, divided into 19,900 ordinary and 100 founders' shares of £5 each. By special resolution passed on October 11, 1889, and confirmed on October 30, 1889, the capital of the Company was raised to £300,000, by the creation of 40,000 new shares of £5 each. At the time of making-up, all the shares had been taken up, the full amounts had been called, and all calls (£300,000) have been paid.

WREXHAM AND DISTRICT ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of the above-named Company, made up to February 15, 1892, was filed on the same day. The Company was registered on December 19, 1889, with a capital of £20,000, in £5 shares. At the time of making up, 115 shares had been taken up, upon which no calls had been made. Nearly all the shareholders are residents in the district. No agreements for the purchase of contracts, plant, businesses, &c., have as yet been filed.

YORKSHIRE HOUSE TO HOUSE ELECTRICITY COMPANY (LIMITED).—The annual return of the above-named Company, made up to January 11, 1892, was filed on March 16, 1892. The Company was registered on June 26, 1889, with a capital of £100,000. At the time of making up, 100 founders' and 7 ordinary shares had been taken up, and upon the 7 ordinary shares no calls have been made. The original signatories are the only shareholders, with the exception of the House to House Electric Light Supply Company (Limited), who hold the 100 founders' shares. (From the above it will be seen that only a portion of this Company's capital had been issued at the time of making up the annual return. Last week, however, a prospectus was issued, inviting applications for £50,000, in 10,000 ordinary shares of £5 each, and 50 founders' shares of £5 each were offered at par to the first 50 subscribers of £500 each of ordinary shares. A noticeable feature in the prospectus is the number of contracts entered into, chiefly with the parent House to House Supply Company, and Messrs. Hammond and Co., whose figures form the basis of glowing anticipations of future profits. Clause 5 of the Prospectus states that "the Directors have secured the services of Messrs. Hammond and Co., of London, as the Electrical Engineers of the Company for the construction of the works;" and Clause 8 states that "tenders will be invited from leading Electrical Contractors for carrying out the work.")

MISCELLANEOUS.—Pollit and Wigzell (Limited), capital £40,000, in £10 shares. Copley, Turner, and Co. (Limited), capital £50,000, in £10 shares.

CITY NOTES, &c.

BENGAL TELEPHONE COMPANY (LIMITED).—The report of this Company for the year 1891 shows that the position of this Company is improving. An available balance, amounting to Rs.54,676 is shown at the credit of profit and loss account, out of which it is proposed to pay a dividend at the rate of 5½ per cent., and to carry forward Rs.6,276. The report states that, on December 31st last, the Company's revenue had amounted to Rs.78,155, the largest on record.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—Notice is given of the proposed drawing of 168 of the Five per Cent. Debentures (1884 issue) of this Company, which will take place at noon on Monday next, the 11th inst., at the offices of the Company, Winchester House, Old Broad-street, London, E.C.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended April 4th were £796, as against £901 for the corresponding period of last year (Easter week), showing a decrease of £116. The total receipts to date, from January 1, 1892, are £11,342, against £10,084 for the corresponding period of 1891, an increase of £1,258.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of March were £4,000, as compared with £4,002 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for the month of March amounted to £2,103, as compared with £1,930 in the corresponding period of last year, an increase of £173

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of March amounted to £59,037, as against £58,447 in the corresponding period of last year, an increase of £590.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—In our advertisement columns will be found particulars of the drawing of 337 Debentures of £100 each, of the Five per Cent. Australian Government Subsidy Debentures. These debentures will be paid off at par on July 1st next at Messrs. Barclay, Bevan and Co.'s, 54, Lombard-street, E.C., and interest will cease after that date.—The accounts of the Company to December 31st last show, subject to audit, a balance of profit of £193,237. 2s. 2d., after payment of three interim dividends. The Directors now propose to distribute on May 4th the usual dividend of 2s. 6d. per share, making a total dividend of 5 per cent. for the year 1891, together with a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the year. The balance of £111,957. 2s. 2d. has been carried to the reserve fund. The share register will be closed from April 28th to May 4th, both days inclusive.—The traffic receipts of this Company for the month of March amounted to £43,805, and to £44,716 in the corresponding period of last year, a decrease of £911.

GATTI'S ELECTRIC LIGHTING STATION.—Rumour has it that this concern is to have the advantage of limited liability shortly.

GLOBE TELEGRAPH TRUST COMPANY.—The Directors have declared an interim dividend of 3s. per share on the preference shares, and of 2s. 6d. per share on the ordinary shares.

GREAT NORTHERN TELEGRAPH COMPANY (LIMITED).—The traffic returns of this Company in March, 1892, were £22,000; 1st January

Digitized by Google

to 31st March, 1892, £62,800; corresponding month, 1891, £64,400; 1890, £60,200.

ELECTRIC CONSTRUCTION CORPORATION.—Mr. W. W. Duncan, in his report for April, deals at considerable length with the subject of electric traction, and again dwells upon the value of Electric Construction Corporation Debentures as an investment.

SUBMARINE CABLES TRUST.—Notice is hereby given that a payment of £1. 2s. 6d. will be made on account of the coupon due on April 15th, on and after 16th inst., by Messrs. Glyn, Mills and Co., Lombard street The coupon should be left with the bankers for examination four clear days before payment.

TELEPHONE COMPANY OF AUSTRIA.—A dividend is announced at the rate of 6 per cent. per annum on the preference shares of this Company for the past half-year.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the fortnight ending March 31, 1892, amounted to £3,047, as compared with £3,046 in the corresponding period of last year, an increase of £1.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ending April 1, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,265.

W. T. HENLEY'S TELEGRAPH WORKS.—Warrants have been posted for a dividend at the rate of 7 per cent. per annum on the preference shares and of 5 per cent. per annum (free of income-tax) on the ordinary shares of this Company, for the year ended December 31st last. The subscribed share capital of this Company is £21,000 preference shares and £67,270 ordinary shares.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 726.—Vol. XXVIII. FRIDAY, APRIL 15, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

Since the classical researches of Hertz, a number of physicists have attempted to get accurate quantitative results with electrical oscillations. The formulæ used by Hertz were confessedly only approximations, as the phenomena are far too complex to be treated in any simple manner. Many difficulties have therefore been encountered before reliable measurements could be obtained, and the merit of surmounting these obstacles is mainly due to French physicists. The latest researches in this direction are those of M. Blondlot, whose work has just received an important testimony to its value in the form of a report presented to the Académie des Sciences by MM. Fizeau, H. Becquerel and Poincaré. The distribution of currents and potentials in such rapid oscillations seems to differ entirely from what obtains for slow alternations, so that the capacity and self induction calculated from ordinary formulæ only appear to hold in special cases. M. Blondlot has succeeded in constructing receivers and resonators in such a way that the ordinary formulæ hold, and has thus been able, not only to obtain reliable measurements, but also to carry out a valuable investigation about the nature of the oscillations themselves. Those who were present at Mr. Tesla's recent lecture will remember his pointing out that the air effects which took place at the surface of the conductors considerably modified the value of their capacity, and accordingly that calculations based on the ordinary capacities would lead to erroneous conclusions. If these effects occur with such comparatively slow alternations as 10,000 per second it is only natural to assume that they will be still more marked with Hertzian oscillations which are 10,000 times as frequent as those used by Mr. Tesla. The wonder rather is that M. Blondlot has succeeded so well.

The reduction in fees for renewal of patents, which was announced in the Budget speech on Monday last, will be hailed with satisfaction by many of our readers. For ourselves, we have not altogether sympathised with the cry for cheaper patents. On the one hand, even the total sum of £154, which has hitherto been the cost of a full fourteen years' term, is but a small fraction of the expense of working a patent of any importance; while, on the other hand, it may be argued that if a patent has not turned out at the end of four years to be worth renewing at an annual fee of £10, it is better that the monopoly should be stopped, in order that other persons may have an opportunity of making something of the invention, if the patentee or proprietor of the patent cannot do so. The effect of the reduction will be to increase the number of small and comparatively unimportant patents, which would otherwise be extinguished. It is estimated that a loss of revenue of "£50,000 for a full year" will be incurred, but there is little doubt that the ultimate effect will be to increase the income of the Patent office. The saving amounts to £51 on a complete patent. Nothing can be more simple to remember than a payment of £4 for the first four years, £5 on the fifth year, and so on, up to £14 for the last year. The patent agents will, of course, spoil the symmetry of this.

According to the *Western Electrician* of April 2nd the Thomson-Houston Company has finally agreed to furnish 2,500 arc lights for the Chicago Exhibition at $20 each, promising to furnish 1,000 more at the same rate if called upon to do so. On their part the Exhibition authorities have agreed that the Thomson-Houston Company shall not be required to furnish any superintendence or help of any kind in the working of the plant. The Standard Electric Company of Chicago are to be given 1,000, and the Western Electric Company 500 lights on the same basis. Thus 5,000 out of 6,000 lamps are provided for. "There is still some talk of seeking the remainder from foreign sources," says our Chicago contemporary, adding that the whole arrangement gives general satisfaction, and all concerned appear to be glad that an agreement has been reached. The deadlock, therefore, to which we alluded last week has thus been removed.

In the lecture which was delivered by Mr. Preece at Liverpool last week, and which we publish in the present issue, a 16-candle 100-volt lamp is assumed to take 0·48 ampere. Knowing that the lamps which are in use in this country take fully 4 watts to the candle even when quite new, we inquired from the author why he took such a favourable estimate. His reply was that while at present it may be most economical to run glow lamps at the degree of incandescence recommended by the manufacturers, the day is rapidly approaching when we may hope to buy lamps at about half the present price. Assuming that the filaments are equal to the present ones, it will not only not be extravagant to run them higher, but, if the present practice is correct, it will be more economical to do so. In speaking of the present quality of filament we hear from several quarters that there have been either some bad batches of lamps of late, or their quality has

Digitized by Google

deteriorated. There have been complaints about short-lived lamps, and these of lamps which last not 600 or 700 hours instead of 1,000, but which break down after a week or two of ordinary domestic lighting. It is only fair to say, however, that the Edison Swan Company investigate these complaints, and substitute fresh lamps if the fault is in the lamp. The staff at Ponders End are no doubt well advised in trying to make an eighteenpenny lamp, but they should take care that these are not put on the market until they are wanted.

Of the various waste forces of Nature to which Mr. Preece has been giving his attention, the "roaring torrent" seems to be most easily persuaded to yield some of its energy to industrial purposes. The utilisation of the power of a flowing river with any reasonable economy is a matter of some difficulty, unless in such exceptional cases as the Rhone or the Rhine, where floating mills are to be found. The least promising force, on account of the heavy cost of plant, is the tide. The word "efficiency" has been sadly misused at times, but Mr. Preece's expression of the efficiency of the transmission of energy by transport of coal is not only correct but original. Even though the efficiency as reckoned from the price of coal at the pit's mouth and the price when delivered at the central station may be only some 25 per cent., there is not at present much inducement to remedy this by transmission of the energy by wire instead of by railway. The Westminster Electric Supply Company will be able to estimate before long the difference between the cost of fuel at their river side and mid-London stations. The capitalised value of the difference will no doubt be considerable.

A calculation ascribed to Mr. Kapp which is quoted by Mr. Preece in his lecture, states that if 10,000,000 H.P. were taken continuously by tide-mills from the energy of the earth, the length of the day would be increased by one second in a century. We made a similar calculation some years ago, and find a note of the figure $8{\cdot}7 \times 10^{22}$ H.P., but have not repeated the calculation. There are about 10^{33} foot-pounds of energy to draw upon, and if our figure and that of Mr. Kapp differ a thousand-billionfold it does not very much matter.

In an article on Coast Protection in the *New Review* for this month, Prof. Tyndall severely criticises the performance of our lighthouses and fog signals, and makes special allusion to the apparatus at St. Catherine's Point. Beginning with the siren, he complains that air has been used instead of steam, and from experiments made at South Foreland, concludes that if steam had been employed on the night of February 2nd last the siren would have made itself heard by the crew of the Eider. Prof. Tyndall gives no reason for preferring steam to air, and loses sight of the ease with which the latter can be stored. Four large cylinders constructed like boiler shells are kept charged with compressed air at St. Catherine's Point, and these, in case a fog comes on suddenly, are able to supply the siren for some fifteen or twenty minutes until steam is raised in the boilers. The boilers are, of course, always under steam, but the fires are banked in the morning when the dynamos are stopped. There is no fear that these air reservoirs will be forgotten and allowed to run down, for the air is employed every night to drive a tiny engine for revolving the optical apparatus. A more uniform, less troublesome and cheaper mode of driving it is difficult to conceive.

Prof. Tyndall's most practical suggestion is the recommendation of flashing; an altogether different thing to a revolving light. Even the flash of signal guns is frequently seen when their reports are inaudible, and the light of the lighthouses with which they are associated is invisible. He contends that by the dispersion and diffusion of fog particles, the spaces between the beams of a revolving light become as luminous as the beams themselves. The revolution of the optical apparatus of a lighthouse, after all, only results in more or less sudden outbursts of light, as far as any distant observer is concerned. Exactly the same effect would be produced by the intermittent extinction or sudden shading of the light; but there would be no blurring of the intervals during thick weather, and even if the direct light could not penetrate the fog, a sharply intermittent glare would be seen. The essence of Prof. Tyndall's idea is, in fact, the substitution of time intervals for space intervals.

Prof. Tyndall very properly objects to the six or seven million candle power which astound the readers of newspapers, and points out that the 730 candle power of the oil light which preceded the electric light at St. Catherine's Point was obtained by direct photometric measurement, while the seven million was derived from calculation. We have already pointed out the absurdity of such figures in these columns, and would remind our readers that at the South Foreland experiments the light was found to be between 10,000 and 30,000 candle power, according to the current and the number of dynamos employed. We have plotted current against candle-power, and find that for these large currents from 50 to 70 candle-power is given for every ampere.

Royal Microscopical Society.—This Society will meet on Wednesday next, at 8 o'clock.

Accumulators in Telegraphy.—Accumulators have entirely displaced primary batteries at the Milan Central Telegraph Office.

Bradford.—At a meeting of the Town Council on Tuesday last, it was decided that the price of electricity should be reduced from 6d. to 5d. per unit, from the 1st inst.

Portsmouth.—The Town Council have applied to the Local Government Board for power to borrow £60,000 for lighting the borough with electricity. There is said to be a strong feeling existing against the scheme, and the application will, it is stated, be strenuously opposed at the public inquiry.

Royal Meteorological Society.—At a meeting of this Society on Wednesday next, at 7 p.m., the following Papers will be read:—"Anemometer Comparisons," by W. H. Dines, B.A.; "The Hurricane over the West Indies, August 18—27, 1891," by Francis Watts.

The Government Grant to the Royal Commission.—The Government have agreed to increase the grant to the British Commissioners for the Chicago Exhibition, from £25,000 to £60,000. This will enable the Commissioners to offer space to British exhibitors free of charge.

Coast Communication.—Sir Edward Birkbeck has accepted an invitation from the Plymouth Chamber of Commerce

Digitized by Google

to a banquet to be given in his honour, on Thursday in Easter week, in recognition of his services in connection with the subject of electrical communication around our coasts.

Huddersfield.—On Thursday last week Mr. Rienzi Walton, M.Inst.C.E., held an inquiry relative to an application by the Huddersfield County Council for sanction to borrow £50,000 for electric lighting purposes. The Town Clerk stated that the ratable value was £422,873, and the total indebtedness of the borough was £2,067,069. There would be provision for 6,660 8 c.p. lamps. The Inspector said that as the matter was of an urgent nature he should do his best to expedite it.

Presentation.—The retirement of Mr. C. Wilson from the position of superintendent of the Cadiz station of the Spanish National Submarine Telegraph Company was made the occasion, a few evenings ago, of presenting him with a gold watch, and Mrs. Wilson with a gold bracelet. The presentation was made at the club rooms, and a number of the members of the English colony were present. Mr. Wilson leaves Cadiz to occupy a similar post at Pernambuco for the South American Cable Company.

Telegraph Rates to India.—In reply to Mr. Henniker Heaton Sir J. Fergusson stated, in the House of Commons, on Monday night, that he had no intention of proposing a reduction of rates and guarantee in regard to India, similar to that lately come to between some of the Australian colonies and the Eastern and Eastern Extension Companies. He had reason to believe that the conditions of commercial life in India would not produce any increase of business commensurate to, or approaching, the loss of revenue which would be the result.

Gas Concessions in France.—A deputation from the Chambre Syndicale des Industries Electriques recently waited on the Minister of Public Works, and laid before him a peculiar difficulty under which the electric lighting industry labours in France. A large number of townships, in order to obtain gas on favourable terms, have granted gas concessions, which prevent any other illuminating company from taking up the local roads for the purpose of laying mains; and now recent decisions of the Conseil d'État threaten to apply the same law to the public highways. The deputation asked that electric light mains should, at least, be permitted under the roads owned by the State.

A Sub-Lacustrine Cable.—A little submarine cable experience is evidently wanted by the Wurtemberg and Swiss telegraph officials. Some time ago an attempt was made to lay a cable in Lake Constance between Romanshorn and Friedrichshafen, for the purpose of connecting the Swiss and Wurtemberg telegraph systems. Although the distance is only 13 kilometres, the attempt failed, owing to the cable having been allowed to run out too quickly, with the result that the ship was still 2 kilometres from the shore when the cable came to an end. The same thing frequently happened in the early days of submarine telegraphy—notably, in the case of the cables laid to Algiers by the French Government.

Large Current Batteries for Experimental Work.—Those who want to work induction coils at odd intervals, says *Industries*, always find the battery troublesome. They use bichromate cells, or various kinds of batteries with queer depolarising liquids, and find them all equally objectionable. Every electrician knows all about Planté batteries, but one is inclined to wonder how often they are used for this kind of work. Nothing can be simpler than to use a few small current cells with a little secondary battery in parallel. There is then no trouble, and for intermittent and occasional work a large current can be obtained. It may seem rather late in the day to mention such a thing as this, but the obvious is frequently overlooked.

The Influence of Tempering on the Thermo-Electric Properties of Bismuth.—G. P. Grimaldi states in *Il Nuovo Cimento* (Vol. XXV., p. 40), that lengthy investigations of the thermo-electric behaviour of pure and impure bismuth lead him to conclude that the thermo-electric power of bismuth free from tin is but little impaired by tempering. On the other hand, if the bismuth contains even a small trace of tin, tempering has a marked effect, increasing with the proportion of tin present. In a sample containing 1 per cent. of tin, the thermo-electric power diminished 47 per cent. Successive heatings cause the impure material to gradually regain its normal value. The couple employed was a copper-bismuth one.

Reduction of the Patent Office Fees.—In his Budget speech on Monday evening, the Chancellor of the Exchequer made the following important announcement with regard to the scale of patent fees to be enforced in the near future. The primary fee of £4 for the first four years will be continued, but from that time onwards the following large reductions will take place:—The fees for the fifth, sixth, seventh, and eighth year will be £5, £6, £7, and £8 respectively, in lieu of £10, as hitherto. In the ninth and tenth years the fees will be £9 and £10, in lieu of £15, as hitherto. During the last four years the fees will be £11, £12, £13, and £14, as against £20. These reductions, which will come into force on September 20th, are estimated to involve a diminution of £50,000 per annum in the Patent Office receipts.

Electric Launches at the Chicago Exhibition.—Tenders for the exclusive privilege of operating passenger boats to be propelled either by electricity, steam, or naphtha, on the lagoons of the Exhibition grounds, were recently opened. Three of the tenders, says the *Western Electrician*, were for electric launches. General C. H. Barney, representing the Electric Launch Navigation Company of New York, offered to construct and operate from 20 to 60 boats 34ft. long, and pay the Exhibition 33⅓ per cent. of the gross receipts. The Columbian Launch Company of Chicago offered the Exhibition 31 per cent. of its gross receipts. This Company proposed to use either electricity or steam. D. R. Proctor, of Chicago, offered to furnish boats operated either by electricity or steam, giving the Exhibition 33⅓ per cent. of the gross receipts.

Glasgow.—At a meeting of the Police Commissioners on Monday last, it was decided to light some nine or ten streets by electricity. The total number of lamps erected will be 106. In moving the approval of the minutes, the Chairman of the Watch and Lighting Committee said that they had a report from the inspector of lighting as to the cost of lighting those streets with electricity, and they found that it amounted to £2,120. To that was to be added a capital expenditure of £2,500 for new electric lamps. It was proposed to wipe off this payment of £2,500 in ten years, which would make the annual cost of the electric light £2,371, or an increase, speaking roughly, of £700 on the present annual expenditure; but the committee were satisfied that this was entirely warranted by the great improvement it would be in the city.

The Proposed Niagara-Buffalo Transmission.—The Oerlikon Company, says *Industries*, has sent in a tender for the construction of the proposed transmission plant between Buffalo and Niagara Falls, a distance of 22 miles. Three-phase currents are to be used. The power to be transmitted is 5,000 H.P. The dynamos, which will be of the multipolar drum-wound armature type, are to be coupled directly to the shafts of the turbines, making 250 revolutions. The proposed pressure is between 600 and 700 volts, and it is to be converted into 25,000 volts before passing to line. The Oerlikon Company propose to use two lines, one for lighting and the other for power; the cost of these is to be £4,000. The guaranteed efficiency of the generators is 96 per cent., and that of the whole line up to the second set of transformers is to be 84 per cent. The total cost of the installation, including exciters and generators and line, is to be £36,000.

Massachusetts Street Railway Statistics.—The second annual report of the Board of Railroad Commissioners of Massachusetts, just issued, gives some very interesting statistics in regard to street railways in that State. The report summarised gives the following statistics for the year ended September 30, 1891:—Aggregate capital of all street railway companies, $19,553,952; total miles of track, 674.13; total cost per mile, $41,763; passengers carried, 176,090,189; average receipts per passenger, 5.06 cents; average cost, 4.05 cents; profit, 1.01 cents against 1.10 cents the previous year. Number of accidents 409, fatal 29. There were 204 accidents on the West End Street Railway system of Boston, 14 of which were fatal; 122 accidents occurred by horse cars and 82 by

Digitized by Google

electric cars. On September 30th, there were in the State 279.44 miles of electric roads, &c., using the "overhead" system an increase of 128.16 miles, and 9.59 miles using storage batteries. There were under construction 13.3 miles on the "overhead" system.

The Commelin-Finot Cadmium Accumulator.—The positive plate of this accumulator, says *L'Industrie Electrique*, is an ordinary Julien positive; the negative plate being preferably an alloy of lead, cadmium, and antimony. The liquid is a solution of sulphate of cadmium, to which 10 per cent. of sulphuric acid is added. MM. Commelin and Finot also propose to employ a positive plate formed of twisted lead strip, holding plugs of lead chloride. On charging, the oxygen oxidises the positive plate as usual, and metallic cadmium is deposited on the negative plate. On discharging, the cadmium combines with the sulphuric acid, cadmium sulphate being re-formed, and the hydrogen liberated from the sulphuric acid goes to the positive plate and reduces the peroxide. The inventors anticipate by this arrangement the complete avoidance of sulphating. The electromotive force of the cell is stated to be 2·5 volts on open circuit, and from 2·2 to 2·15 volts during discharge. The output per pound of plate is 24·5 watt hours.

The Grounding of the Neutral in the Three-Wire System.—"It has been for some years past," says the *Electrical Engineer* of New York, "the general practice among companies operating low-tension three-wire circuits, more particularly among the various Edison illuminating companies in the country, to ground the neutral. This practice was introduced in a few stations as an experimental protection against lightning, and for a long time met with no opposition on the part of the underwriters; but it would appear that a recent fire in New York has brought forward prominently the question of the possible dangers involved in this practice. The New York Board of Fire Underwriters, at their last meeting, went even so far as to pass a resolution requiring the electric companies to remove all such grounds now existing on their circuits before October 1, 1892, and to make regular weekly reports of the tests of their circuits as called for in the requirements of the Board, failing in which the superintendent of the Survey Department is directed to decline to grant certificates."

Post Office and Telegraph Profits.—The following extract from Mr. Goschen's Budget speech will be read with interest:—"The Post Office increase is £611,000, of which £490,000 is due to an increase in salaries and wages. That is how our estimates are swollen; and, while the Government have been anxious to meet the fair and equitable claims of those who are employed in that service, we have endeavoured to deal with the subject at the same time in a spirit of proper economy. Now, as regards telegraph services, one observation I commend to some postal reformers. The average profit in every £1 of telegraph receipts during the last five years has been 3d. The expenses have been 19s. 9d., and the profit 3d. During the previous five years the expense was 18s. 6d., and the profit 1s. 6d. We have now come down to this position, that the increase of telegraph communication and the further facilities as to addresses, so dear to some postal reformers, will probably leave us in a deficit. The increased postal revenue, which may be called £350,000 a year, is far more than balanced by the increase in expenses, and the margin of revenue at the disposal of the Exchequer is rapidly being diminished. The gross incomes of the Post Office and Telegraphs for the financial year 1891-92 amounted to £12,630,000, or £30,000 more than the estimate."

The Application of Electricity to Mining.—At a recent general meeting of the members of the South Staffordshire and East Worcestershire Institute of Mining Engineers, a discussion took place upon Mr. L. B. Atkinson's Paper on this subject. Mr. R. S. Williamson and Mr. W. Wardle contributed short practical Papers on the same subject, giving their experience of the use of electrical machinery. Mr. Williamson stated that so far as his experience went he found that there was less trouble with electricity than with compressed air, and that for working a long distance from the shaft the former was of much greater utility. Mr. Wardle dealt with the approximate cost of electricity as a motive power compared with compressed air, remarking that the cost of laying down plant for electricity in a mine with which he had been connected was £1,000, whilst he estimated that the cost of compressed air appliances would have been £2,156. The Chairman (Mr. W. F. Clark) said he took it that the general opinion was that electricity was the most efficient power when work had to be done a long way from the shaft, and it seemed to him that electricity for that purpose had given compressed air its deathblow. Mr. Collis said they had come to the conclusion that electricity would supersede compressed air for work a long way from the shaft, but that it would not compare with the use of ropes worked from the surface.

The Oxford and Cambridge Boat Race.—A conspicuous feature of the University Boat Race this year was the electric launch fleet. The charging station of the General Electric Power and Traction Company was crowded with visitors, as were also Messrs. Woodhouse and Rawson's, and Mr. Sargeant's barges. We learn from the General Electric Power and Traction Company that the electric launch season has opened well.—The Boat Race, as reported by the Exchange Telegraph Company this year, was a marvel of telegraphy, the progress of the boats at intervals of a few minutes along the entire course having been published all over London almost as the crews were passing the points indicated; and immediately following the result there was despatched a complete description of the race from start to finish, which was in the hands of the newspapers and others provided with that Company's instruments long before a single Pressman was able to land his "copy" from the Press boat at Mortlake, and also long before the pigeons despatched from the scene were able to settle down in an homeward direction. The Press boat, as it steamed up the Thames, paid out a cable consisting of a 7-strand conductor, insulated with vulcanised rubber with warps and braids of flax, which had been manufactured by Messrs. Walter T. Glover. The instruments used were Morse sounders. In consequence of this enterprise, the London papers containing the result and full details of the race, were on sale within four minutes after the Oxford crew had passed the winning post. Between 12.8 and 12.37 no less than 13 messages were sent, beginning with the announcement of the winner of the toss, and ending with a short description of the race, containing over 150 words. We learn that some 18 years ago a similar experiment was made.

Power Generators for the Chicago Exhibition.—On March 18th the tenders for the furnishing of power generators for the motor service in the Chicago Exhibition were opened. Five bids were received, says the *Western Electrician*. The Eddy Electric Manufacturing Company of Windsor, Conn., offered to furnish the 300 H.P. generating apparatus for the transportation building free of cost. The National Electric Manufacturing Company of Eau Claire, Wis., offered to furnish the apparatus for this building for $2,500. The Western Electric Company proposed to furnish about 400 H.P. for $6,500. The Mather Electric Company of Manchester, Conn., bid on the mines building, and offered to furnish 600 H.P. for $2,450. The Thomson-Houston Company put in a bid for furnishing all the apparatus (2,500 H.P.) for $52,900. This company also asked for the exclusive right of furnishing exhibitors such power as might not be included in the general plant, and charge therefor $40 per H.P. It also wanted the sole right to furnish all supplies, and the right to sell or lease meters for the measurement of the amount of power used.—According to latest advices, all the tenders save that of the Eddy Company have been rejected. The Grounds and Buildings Committee have adopted a recommendation that this Company should be offered the privilege of furnishing from 1,000 to 1,500 H.P., at the rate of $2.50 per H.P. In the event of the Company agreeing to furnish 1,500 H.P. capacity on the terms mentioned, all other firms wishing to supply generators for the World's Fair plant would have to do so free of cost. In case, however, the Eddy Company chooses to supply but 1,000 H.P., the Mather Company will be given an opportunity to furnish the capacity mentioned in its bid at the rate of $2.50 per H.P.

SOME RECENT RESEARCHES ON ELECTRICAL OSCILLATIONS.*

BY MM. BLONDLOT AND DUFOUR.

In order to obtain satisfactory results with electrical oscillations, M. Blondlot advises the use of a special form of exciter devised by himself. This consists of a condenser formed of two circular discs, α and β (Fig. 1), about 12cm. in diameter, placed at 1cm. distance from each other. To these plates are soldered two copper wires, $\alpha\ \gamma$, $\beta\ \delta$, 3mm. in diameter, terminating in balls, γ and δ, and bent so that each forms a semicircle of about 2 metres in diameter. The balls γ and δ are connected with the poles of an induction coil, so that when the latter is worked an oscillating current is set up in the circuit $\alpha\ \gamma\ \delta\ \beta$, across the air gap $\gamma\ \delta$.

The secondary circuit is formed of a copper wire bent in a circle whose diameter is less than that of the primary by about 1cm. This wire is enclosed within an india-rubber tube and lies beside the primary. Its position is indicated in Fig. 1, by the dotted line. It terminates in two points M N, situated near the spark gap $\gamma\ \delta$. The sparks which are induced between M and N are, in certain cases, longer than those in the primary circuit, and M. Blondlot has succeeded in obtaining sparks in this way as long as 11mm.

To transmit oscillations to a distance, two long parallel wires are soldered to M N, and the field between them is explored by means of a resonator.

Several advantages are secured by the use of this type of oscillator. The phenomena are intensified and are thus more

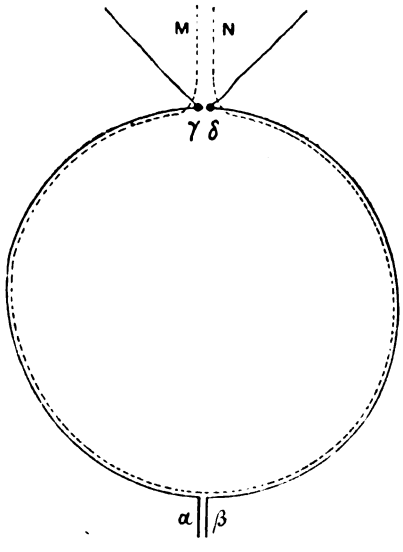

FIG. 1.

easily observed. The primary spark is always oscillatory, even though the balls $\gamma\ \delta$ are left unpolished. The period of the exciter can be readily changed by adjusting the distance between the plates $\alpha\ \beta$ of the condenser, and the greatest advantage of all is that troublesome electrostatic effects,† due to charges on the surface of the wires, are overcome.

To increase the action of the resonator the following device is resorted to:—The parallel wires M N′, N N′ are laid at a distance of about 2cm. from each other, except where the resonator is placed. Here (as indicated in Fig. 2) the wires are bent into the shape of a rectangle, $C_1\ D_1\ E_1\ F_1$, a little larger (about 0·5cm.) than the resonator C D E F. With this arrangement the inductive effects are very strong. As, however, the resonator cannot easily be moved along the wires M M′ and N N′ the wave-lengths are determined by the method of movable shunts already described.‡

By making use of the above form of exciter MM. Blondlot and Dufour have been able to carry out some important experiments, showing the effect of a want of symmetry in the circuit on the mode of propagation of the electric waves.

* Abstracted from the *Comptes Rendus*, February, 1892.

† *See* V. Bjerkness, *Wied. Ann.*, Bd. XLIV., p. 520.

‡ See *Journal de Physique*, Vol. X., p. 554.

The apparatus they used is illustrated in Figs. 3 and 4. The fixed resonator is placed at R S, and the adjustable shunt is indicated by $\mu\ \nu$. The experiments consisted in finding by trial the position of the bridge $\mu\ \nu$, for which the spark of the resonator disappeared. The length of the wire R $\mu\ \nu$ S in this case was the half-wave length.

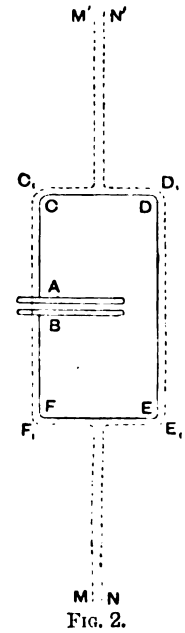

FIG. 2.

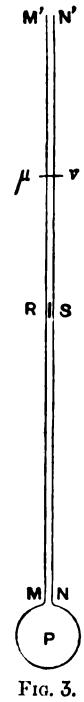

FIG. 3.

To show the effect of dissymmetry, the wire N N′ was cut near the point N, and two parallel wires N K were soldered to the two points so formed. The length N K was adjustable at will.

In this way the authors have established the fact that the length of the loop N K has no influence whatever on the position of the bridge $\mu\ \nu$, for which the resonating spark disappears, or in other words that *the wave length as measured by the resonator is independent of the dissymmetry of the two wires which transmit the electro-magnetic waves.*

The experiment was repeated many times under most diverse conditions. The length of the loop N K was varied from 0 to 30 metres without observing any appreciable change in wave length. In the extreme case the length N ν was 42 metres, while M μ was only 12. The capacity of the resonator was also changed without apparently altering the wave length.

These experiments are in accordance with those of Sarasin and de la Rive. The latter showed that the wave length was independent of the exciter, while these show that the conductors transmitting the undulations have no influence on the wave length so measured.

The theory of resonance to which independent support is given by M. Bjerkness' experiments* for the case of propagation through air, when adapted to the case of propagation along wires, can be thus stated. Each wave communicates two impulses to the resonator, the first by direct propagation along

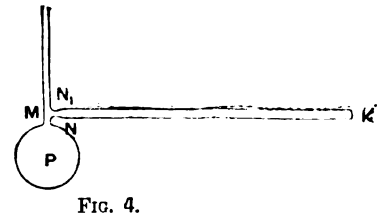

FIG. 4.

the wire, the second after the wave has travelled across the bridge to the other wire. The second impulse reinforces or annuls the first, according as the resonator during the interval has performed an even or uneven number of half vibrations. This only depends on the length R $\mu\ \nu$ S, and not on the symmetry of the circuit.

* V. Bjerkness., *Wied. Ann.*, Bd. XLIV., p. 93.

Digitized by Google

According as the waves travelling along the two wires are in phase or out of phase at the resonator, the resonance effect for a position of the bridge other than that of extinction will be more or less intense. M. Poincaré has pointed out that the phenomena will be most strongly marked when the length of the loop N K is 0, λ, 2λ, ..., and least apparent when this length is $\frac{\lambda}{2}$, $\frac{3\lambda}{2}$, &c. This, in fact, is what the experiments show.

M. BLONDLOT'S RESEARCHES ON HERTZIAN OSCILLATIONS.

The following is a translation of a report recently presented to the Académie des Sciences by MM. Fizeau, H. Becquerel, and Poincaré relative to a memoir by M. Blondlot, in which he details his researches on Hertzian oscillations.

The memoir about which we have the honour to report to the Académie contains a large number of important results relating to Hertzian oscillations. In the numerous researches which have had Hertz's discovery as their point of departure, use has often been made of a formula due to Sir W. Thomson, according to which the period of an oscillatory discharge is equal to a constant factor 2π, and to the mean proportional between the capacity of the condenser and the self-induction of the wire connecting the coatings. This formula, deduced from theoretical considerations, had not received the corroboration of experiment in a sufficient manner. Previous verifications related only to oscillations much too slow; and we might question whether it was legitimate to apply the formula to oscillations the period of which is less than the one hundred millionth of a second. The experiment of M. Lecher, which stood, moreover, by itself, and was very indirect, had given rise to several objections. The work of M. Blondlot fills this gap.

As we know, Hertz in his first experiments made use of apparatus consisting of three essential parts—an exciter, a system of two long metallic wires, and a resonator. M. Blondlot introduced important modifications into each of these three parts, for the purpose either of reinforcing the effects obtained, or of facilitating the measurement of the capacity and self-induction of the resonator. The exciter consists of a condenser, the coatings of which are united by a circular wire containing a spark gap. By altering the distance apart of the plates, it is thus possible to vary the capacity and obtain a more perfect resonance. The excitation is transmitted to the long conducting wires not by electrostatic induction, as in Hertz's experiments, but by electro-dynamic induction. These conducting wires form, in fact, a closed circuit, part of which is brought near the circular wire of the exciter.

The modifications made in the resonator merit even more attention, since we know from the experiments of MM. Sarasin and De la Rive that it only depends upon the resonator what wave-length is observed. With the resonators hitherto employed it was impossible to verify Thomson's formula. The extreme capacities being very small the length of half the wave was in all cases a little longer than the length of the wire; with these capacities at zero there would be a node at either end. The measurement of the wave-length could not, therefore, tell us anything as to the propriety of employing the formula. M. Blondlot's resonator consists of a condenser of large capacity, the coatings of which are united by a relatively short wire. Owing to this arrangement we need not trouble about displacement currents, which are localised almost entirely in the excessively small thickness of the insulating plate.

The wave-length is measured directly, and the same with the capacity of the resonator, which we can determine experimentally by the classic method of Maxwell. The self-induction, on the contrary, can only be determined by calculation, which is legitimate if we assume on the one hand that Neumann's formulæ are applicable to such rapidly alternating currents, and, on the other, that the currents flow through the entire wire. This last condition is certainly not fulfilled in the case of ordinary resonators, but it is allowable to hope that it is fulfilled sufficiently well in the case of the new apparatus, where the extreme capacities are large.

M. Blondlot having varied the capacity and self-induction in the proportion of 1 to 4, finds, (i.) that the wave length is proportional to the square-root of the capacity, which verifies Sir W. Thomson's first law; (ii.) that the wave-length is proportional to the square-root of the coefficient of self-induction calculated as pointed out, so that everything happens as it would if the second law of Sir W. Thomson were correct, and the method of calculation were legitimate. It remains to complete the verification of the formula to measure the numerical coefficient which enters into it, and which ought to be equal to 2π, but there is no means of doing so. We might, perhaps, try to do so in the case of oscillations of a few thousands a second, and this should be a spur to investigators, but even then we should still have the right to ask if the coefficient did not vary when the period became a million times shorter.

It is none the less interesting to see what results are obtained when we give this coefficient the value attributed to it in Sir W. Thomson's theory; some consequences of which theory, as we have seen, have just received experimental corroboration. We can then calculate the speed of electro-dynamic induction. Applying this mode of calculation to his experiments, M. Blondlot has worked out fairly concordant numbers approximating the speed of light.

Other experiments of the learned physicist of Nancy deserve equal attention. They give us some information, in fact, as to the real nature of Hertzian oscillations, and appear to confirm the ideas which tend to prevail since the researches of MM. Sarasin and De la Rive. M. Blondlot has investigated, together with M. Dufour, the influence of a loop, and therefore of a dissymmetry introduced into the long-wire circuit. If the nodes and ventral segments pre-existed in the wires, and were only revealed by the resonator, as was thought some years ago, the presence of the loop would certainly displace them. It was not so; the position of the nodes and ventral segments was not affected. But when the length of the loop was varied it was ascertained that the intensity of the ventral segments varied periodically, and offered a series of maxima and minima. Things come therefore to pass as if two disturbances of very short duration left the exciter by the two wires, propagated themselves along these wires, and communicated to the resonator, by passing and repassing close to it, a certain number of impulses which put it into vibration, and the effects of which are additive or subtractive according as the interval of time which separates them is an even or uneven multiple of half the wave peculiar to the resonator. Another fact brought out by M. Blondlot's researches is the progressive diminution of these disturbances as they are propagated along the wires.

Such are the results of these researches; some may be regarded as definitely achieved, others remain to a certain extent hypothetical, since they are based partly on theoretical considerations, which are not yet completely verified. In any case they constitute as a whole one of the most important advances made in this branch of science since the experiments of MM. Sarasin and De la Rive. We are of opinion that there is reason to thank M. Blondlot for his communications, and to congratulate him for having thrown some light on one of the most important questions in natural philosophy.

CRYSTAL PALACE EXHIBITION.

The exhibit of the Brush Electrical Engineering Company, like those of several other important firms, loses a great deal of its effect by being divided into two parts. This scattering of the stands must add materially to the expense of the exhibitors; and the arrangement of the catalogue is, if possible, still more confused than that of the Exhibition. We have already described one or two features of the Brush Company's show; and we illustrate this week the improved method of mounting the coils of the Mordey alternator. In the early forms of this machine, the coils were bedded against the periphery of the ring which holds them in place. The cylindrical surface of the ring was easy enough to tool, but the mounting of the segments against it, and making a thoroughly stiff job of the whole, presented considerable difficul-

Digitized by Google

ties. The work would be difficult enough if, instead of coils, solid metal castings had to be thus fitted; but, as has been found by all dynamo makers who have attempted to strike out new lines, the unmechanical properties of insulating materials call for exceptional constructive skill. In the new form of armature, which can be built without trouble to a very large diameter, the coils (see Fig. 1) are bolted flat against a web or internal flange. The bed being flat, not only is the mechanical work very much easier, but the segmental coils being free to slide in their own plane before the bolts are finally tightened, can be set up towards the centre, thus locking each other, owing to their wedge shape. The coils are mounted between substantial ebonite cheeks, and are held against the flange by three bolts in slightly oblong holes. Set screws, with tommy holes, are provided at the back of each coil, and these bear against the outer ring of the casting. The coils being screwed up finger-tight, these set screws are turned one by one, gradually forcing all the segments together. It will be remembered that the coils of the Ferranti dynamo are forced home under hydraulic pressure, until pins can be fitted into holes in the castings which carry them. These castings are mounted in the main hub of the armature, but depend for their lateral support on an insulating cement. The ease with which any coil of a Mordey alternator can be replaced and adjusted compares very favourably with the Ferranti machine, which it in some respects resembles. The nuts of the Mordey armature are locked by

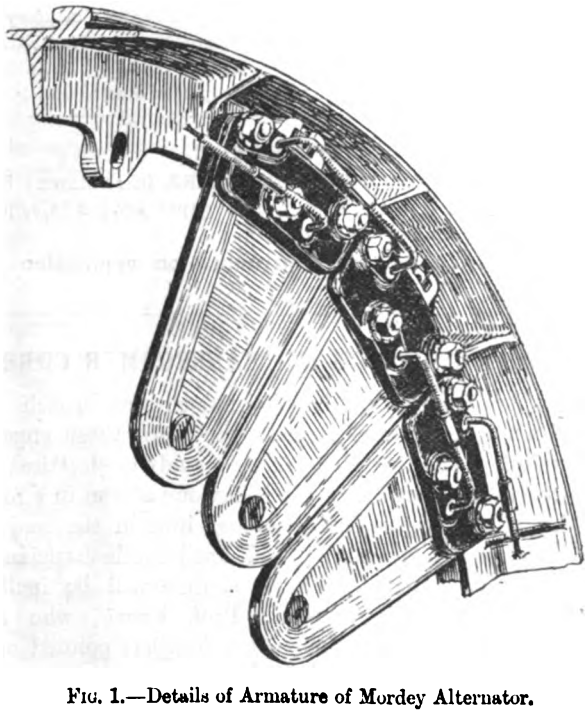

Fig. 1.—Details of Armature of Mordey Alternator.

means of sheet brass clips of a star shape, the arms being turned up against the sides of the nut.

While we have succeeded in finding little that is new, the search for something that has not already been described brings home very forcibly the very stable and developed state which has been reached by makers of electrical machinery and apparatus. But there is a very attractive department in which one might reasonably expect to find continual novelty, and that is in the fittings for electric light for domestic use. We have already expressed our inability to discover much that is artistic or original. Our attention has been specially invited to the stands of Messrs. Benham and Froud. The excellence of the productions of this firm is well enough known in other branches of decorative work, but in electric light fittings there is a little too much massive magnificence. Some of their fittings would do admirably for a palace or a big hotel. An Alfred Stevens' mantelpiece or the equipment of the chancel of a cathedral appears to be better understood by this firm than a simple bracket for a drawing-room. One of the best specimens of design is to be found in a dining-room shown by Messrs. Rashleigh Phipps and Dawson. It would be easy to pass through the room without noticing it, so poor is the general lighting; and the sight of a dining-room table with a gravelly grave in the middle of it, half filled with dank water plants, is enough to chill the most convivial gourmet. But it is original. The central pendant (Fig. 2) and the side brackets are designed by Mr. W. Bainbridge Reynolds, of 138, Lavender-hill, S.W., and symbolize the solar system, the centre light being the sun, and the brackets various planets. Illumination is the least that might be expected from the sun,

Fig. 2.

but the panels of the dome are filled with thick celluloid, to represent ivory, and the upper light is so swathed in silk that the really fine design of the ironwork, which is all forged and riveted, and partly polished, is nearly lost in the obscurity of a very gloomy ceiling. A general fault in electric light brackets is that, while very rarely objects of beauty in themselves, they are much too strong as mere supports for glow lamps. The principle of suitability in decorative art demands that the intention and object of a thing should be regarded. A bracket to carry a glow lamp, holder, and shade, even if designed with a factor of safety of 10, would be a rather fragile affair. The artist has in this case provided spheres to represent the planets, and these, at all events, give some appearance of a load for the very ornamental brackets to carry. The illustration of the centre piece is reproduced from a drawing by Mr. Reynolds. A little symbolism such as this is all very well; but Messrs. Rashleigh Phipps and Dawson, who might have displayed their goods in a more harmonious and artistic style, have so overdone the emblematic business that they have had to provide a small book to explain their devices.

EDDY CURRENTS IN TRANSFORMER CORES.

The development of the alternate-current branch of electrical engineering has forced upon both those engaged in manufacture and those who make a study of electrical science a better acquaintance with the behaviour of iron in a magnetic field. MAXWELL practically ignored iron in the majority of his electromagnetic work; and until mathematicians have been provided with reliable data, they will be inclined to follow him in this respect. Prof. EWING, who has so exhaustively dealt with magnetisation, has pointed out that no subject has profited more by the beneficent reaction of practice upon science. While the last pages of his book were passing through the press Prof. J. J. THOMSON demonstrated that iron continued to be strongly susceptible to magnetisation, even under the extremely rapid oscillatory discharge of a Leyden jar. The combined efforts of two such men as Professors EWING and J. J. THOMSON cannot but produce valuable results. In the article which we published last week, the Professor of Experimental Physics alluded to some investigations on the absorption of energy by iron under Leyden jar discharges, and remarked that he understood from the Professor of Mechanism and Applied Mechanics that this question was of some interest to electrical engineers.

The results as to the influence of eddy currents just obtained by these Professors will probably cause general surprise. Anyone acquainted with the excessive heating which occurs in solid cores when placed in an alternating magnetic field will, however, readily agree that the magnetic force due to these currents must be quite comparable with that of the field which causes them, and that consequently they must have a considerable influence in

Digitized by Google

modifying the distribution of the lines of force. One of the well-known experiments of Professor ELIHU THOMSON consisted in showing the violent repulsion existing between the eddy currents generated in solid copper bodies, and the pole of an adjacent electro-magnet fed with alternating currents. The specific resistance of iron is after all not so very large compared with copper; and as the magnitude of the eddy currents is inversely proportional to this quantity, the effect on solid pieces of iron must also be very striking. In fact, a solid piece of metal placed in an alternating magnetic field must be regarded as the short-circuited armature of a dynamo, and if the piece is of any appreciable size, a large amount of energy will be absorbed by the metal. The currents induced will be excessive, and the magnetic forces exerted by them in their immediate neighbourhood must have a most important effect on the lines of force. The tendency of the eddy currents is to neutralise the influence of the external magnetic forces, and when the medium in which the eddies circulate is of high conductivity, MAXWELL has shown that the demagnetising forces are of very nearly the same strength as the impressed magnetic forces; a similar equilibrium, as every one knows, takes place in the primary coil of a transformer where the back electromotive force generated is of practically the same magnitude as the voltage impressed on the primary.

The theory given by the authors does not take into consideration the loss of energy caused by hysteresis, since it was necessary in the calculations to assume constant permeability, and therefore that hysteresis did not exist. The effect of the screening action of the eddy currents must, however, have the result of increasing the waste due to this cause. The loss of energy per square centimetre is proportional, as Mr. STEINMETZ has shown, to the density of the magnetic lines when raised to the power 1·6; so that, if the lines of force are crowded towards certain parts of the core, the total loss is greater than if the lines are uniformly distributed.

But if the loss by hysteresis is increased by this screening action, the loss in eddy currents is diminished, for the crowding of the lines of force towards the surface of the iron must render them less effectual in generating currents in the core. Unless the core is finely laminated, the eddy current losses are so much more important than those caused by hysteresis that the effect of the screening must, on the whole, be to diminish the heating of the iron. With very thin plates, such as are used in transformers, this result may be reversed; but in such cases the phenomena observed by Profs. EWING and THOMSON are not very marked. The importance of the investigation is, indeed, chiefly due to the fact that the necessity of using very thin plates in transformers is brought out very clearly. When the core plates are laminated as much as is found necessary in practice in order to reduce the eddy current losses within reasonable limits, the screening effects described are almost negligible. For plates whose thickness lies between a quarter of a millimetre and half a millimetre, the density of the magnetic lines is, in fact, only about five per cent. greater near the surface than at the centre.

The investigation affords a rather good instance of the way in which practice and theory tend to diverge from one another. Only when, as in this case, the chief place is given to economic considerations, can theoretical work be expected to have a useful bearing. Engineers, by simply striving to get an efficient transformer, have found it needful to so laminate the core that the abnormal phenomena, disclosed by the Cambridge Professors, are comparatively unimportant. There must be a great number of such effects which, for the same reason, have as yet escaped notice.

ON MAGNETIC SCREENING, EDDY CURRENTS, AND HYSTERESIS, IN TRANSFORMER CORES.

BY PROF. EWING, M.A., F.R.S.

Electrical engineers are familiar with the direct effect of Foucault or eddy currents in causing dissipation of energy, and the consequent necessity of laminating iron which is to be subjected to rapidly alternating magnetic forces. But it appears to be less fully realised that eddy currents have another important effect, also of much practical interest in relation to transformers. I refer to the magnetic screening which they exert upon the interior of any plate or wire in the magnetic circuit. They prevent it from experiencing so wide a range of alternating magnetic force as the skin of the plate or wire experiences; and hence the greatest value of the mean magnetic induction in the core is less than it would be if the same exterior magnetic force were kept steadily applied. In consequence of this, it becomes necessary to apply a stronger external magnetic field in order to force the mean induction up to any assigned value—stronger, that is to say, than the field which would be sufficient if this screening did not occur. And hence the screening occasions two indirect losses: first, the loss due to hysteresis proper is augmented; and, second, the loss due to the magnetising current is also augmented.

When the plates of the core are comparatively thick, and especially when the frequency is comparatively high, the magnetic screening may become so influential that virtually only a small part of the thickness of the plate ever comes into play. The forced electro-magnetic wave which is set up, at the skin, by the externally applied alternating force, penetrates but a little way into the plate before its amplitude is reduced to a mere fraction of the skin value. The influence of magnetic screening turns out to be surprisingly great. For instance, when a plate of soft iron, two millimetres thick, is exposed (in the manner in which the plates in a transformer core are exposed) to an alternating magnetic force (of any moderate strength) with a frequency of 100, the portions of the metal which lie in the middle of the thickness experience only about one-eighth of the force which is applied to the skin. And even when the plate is only one millimetre thick, the force at the middle is but 52 per cent. of the force outside, under this same frequency of 100 periods per second.

The mathematical investigation which has been published by Prof. J. J. Thomson (*The Electrician*, April 8th, page 599) gives us the means of tracing, from point to point of the thickness of the plate, the value which is reached by the alternating magnetic force there in comparison with the value outside, so far as the reduction of the amplitude within the plate is due to eddy currents. No doubt there is a further reduction due to hysteresis; the wave as it penetrates loses energy through hysteresis as well as through generating eddy currents, but of this the theory does not take account, inasmuch as it assumes a constant value for the magnetic permeability. Hence the theory rather understates than overstates the extent of the magnetic screening. Prof. Thomson's equations also serve to determine the amplitude of the mean magnetisation taken across the plate, the rate of dissipation of energy by eddy currents, and the retardation of phase which the magnetisation suffers, on account of eddy currents, as it penetrates into the plate. From the values which the magnetic force reaches at various depths, we may further find the dissipation of energy due to hysteresis by taking advantage of the results of experiments made with slow cycles.* My object in this Paper is to follow up Prof. Thomson's investigation by applying to his equations some of the results of my own experiments, in order to examine the extent to which the screening due to eddy currents actually takes place, and to give numerical values of the losses that are due, on the one hand, to eddy currents, and, on the other, to hysteresis. The examples to be given relate to soft-iron plates, under the conditions in which they might be used in transformers, and may serve a useful purpose by indicating the extent to which it is desirable in practice to carry the lamination of the core.

* On the assumption, that is to say, that the work of magnetisation $\int H\,dI$ is the same in a fast cycle as in a slow one.

Digitized by Google

In what follows

H_0 is the amplitude of the alternating magnetic force at the surface of the plate. It is supposed that this force varies in a simple harmonic fashion.

a is the half thickness of the plate in centimetres.

μ is the magnetic permeability of the material of the plate, which is assumed to be sensibly constant throughout the range of forces that are dealt with.

σ is the specific electrical resistance of the plate.

n is the number of periods (double alternations of the force) per second.

H_x is the greatest value which the alternating magnetic force reaches (in each period) at any point within the plate, the distance of the point from the middle of the thickness being x.

H_1 is the mean maximum value of the magnetic force, that is to say, it is the mean value of H_x from one side of the plate to the other.

H_2 is the maximum mean value of the magnetic force, that is to say, it is that value of (uniform) magnetic force which would cause the whole magnetic induction in the plate to reach the same value as it does reach in each period at the instant when it is a maximum. H_2 is not identical in value with H_1, because of the difference in phase at different depths.

E is the work (in ergs) wasted in eddy currents per second per cubic centimetre of the iron.

For brevity m is used to denote the quantity $2\pi\sqrt{\frac{\mu n}{\sigma}}$.

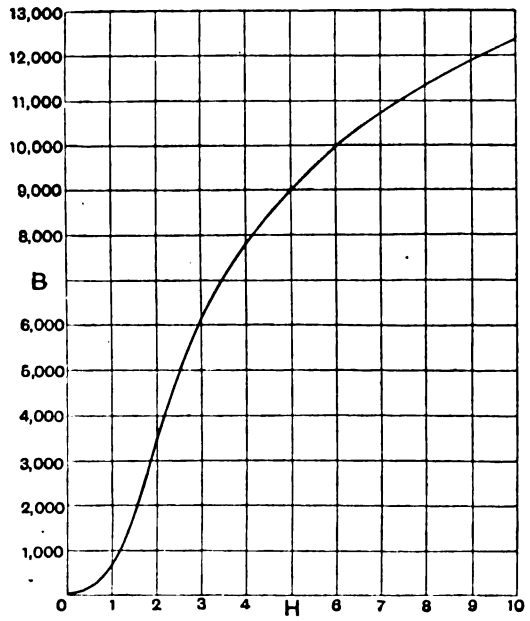

FIG. 1.—Curve of magnetisation of sheet iron.

Prof. Thomson's expression for the amplitude which the alternating force has at any point within the plate at a distance x from the middle of the thickness is

$$H_x = H_0 \left(\frac{\epsilon^{2mx} + \epsilon^{-2mx} + 2\cos 2mx}{\epsilon^{2ma} + \epsilon^{-2ma} + 2\cos 2ma} \right)^{\frac{1}{2}},$$

which may also be written

$$H_x = H_0 \left(\frac{\cosh 2mx + \cos 2mx}{\cosh 2ma + \cos 2ma} \right)^{\frac{1}{2}}.$$

The last form is handier when a table of hyperbolic cosines is available.* Similarly, the work spent on eddy currents is

$$\frac{H_0^2 m\sigma}{16\pi^2} \left(\frac{\sinh 2ma - \sin 2ma}{\cosh 2ma + \cos 2ma} \right)$$

per unit area of the plate, and hence

$$E = H_0^2 \frac{m\sigma}{32\pi^2 a} \frac{(\sinh 2ma - \sin 2ma)}{(\cosh 2ma + \cos 2ma)},$$

and

$$H_2 = \frac{H_0}{ma\sqrt{2}} \left(\frac{\cosh 2ma - \cos 2ma}{\cosh 2ma + \cos 2ma} \right)^{\frac{1}{2}}.$$

In applying these expressions to the sheet iron core of a transformer, we may take σ to be 10,000 and μ to be 2,000. In justification of this value for μ reference may be made to Fig. 1, which gives the results of a recent test I have made of sheet iron: from that it will be seen that throughout the range of magnetisation usual in transformers, say from $B = 8{,}000$ down to 4,000 or less, the permeability is fairly represented by 2,000. We must assume some particular frequency, and I have taken 100.

Substituting these numbers, we have

$$m = 2\pi\sqrt{\frac{2{,}000 \times 100}{10{,}000}} = 28{\cdot}1$$

Take now the case of a plate 1 millimetre thick. Here $2ma = 2{\cdot}81$. The value of H at the middle of the thickness ($x = 0$) is

$$H_0\sqrt{\frac{2}{7{\cdot}389}} = H_0 \times 0{\cdot}520;$$

and for other value of $\frac{x}{a}$, namely,

	0·2	0·4	0·5	0·6	0·7	0·8	0·9
$\frac{H_x}{H_0}$ =	0·521	0·538	0·561	0·601	0·664	0·750	0·861

The variation of H_x across the plate is shown graphically (by the curve marked "1mm.") in Fig. 2. The mean height of this

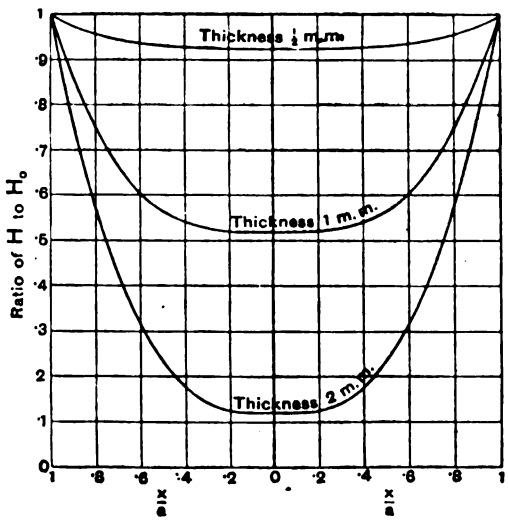

FIG. 2.—Distribution of magnetic force across iron plates of various thicknesses, when the frequency of alternation is 100.

curve is found to be 0·629 of the height at the ends, that is to say, at the surface of the plate. In other words,

$$H_1 = H_0 \times 0{\cdot}629.$$

The value of H_2 is directly calculated from the expression given above, which (since $\frac{1}{m\sqrt{2}} = 0{\cdot}02516$) may be written,

$$H_2 = H_0 \frac{0{\cdot}02516}{a} \left(\frac{\cosh 2ma - \cos 2ma}{\cosh 2ma + \cos 2ma} \right)^{\frac{1}{2}}$$

When the thickness is 1mm. this gives,

$$H_2 = H_0 \times 0{\cdot}564,$$

and this is the effective magnetic force which is to be considered in reckoning the number of lines of induction which suffer reversal at each alternation. This effective induction is of course μH_2.

* I have found Mr. Blakesley's tables, published by the Physical Society, a most useful labour-saving appliance in this connection.

Digitized by Google

To find the waste by eddy currents we have $\frac{m\sigma}{16\pi^2} = 1780$, and when the thickness is 1mm.,

$$E = H_0^2 \times \frac{1780}{0{\cdot}1} \times 1{\cdot}076 = 19140\, H_0^2$$

Similar calculations for plates of other thicknesses give results which are summarised in the table below :—

Thickness of plate in millimetres.	Ratio of H at middle to H_0 (at surface).	Ratio of H_1 to H_0.	Ratio of H_2 to H_0.	$\frac{E}{H_0^2}$.
2	0·120	0·342	0·250	8885
1·5	0·245	0·42	0·341	12370
1	0·520	0·629	0·564	19140
0·75	0·739	0·82	0·793	20290
0·5	0 925	0·940	0·932	14220
0·25	0 995	0·996	0·996	4080

It may be useful to add figures and curves showing the variation of magnetic force across the thickness of the plate in the case both of comparatively thick and thin plates. Figures for the plate, 1mm. thick, have been given above.

For plates 2mm. and ½mm. thick respectively we have

	Values of H/H_0					
	$x/a = 0$,	0·2,	0·4,	0·6,	0·8,	1·0
Thickness 2mm.	0·120,	0·125,	0·173,	0·316,	0·580,	1·00
Thickness ½mm.	0·925,	0·925,	0·927,	0·935,	0·956,	1·00

The curves of Fig. 2 show the distribution in these two cases as well as in a plate 1mm. thick. It is interesting to notice how, with the assumed frequency, a great part of the interior of the 2mm. plate almost escapes magnetisation. On the other hand, the ½mm. plate is magnetised with a fair degree of uniformity throughout its whole thickness.

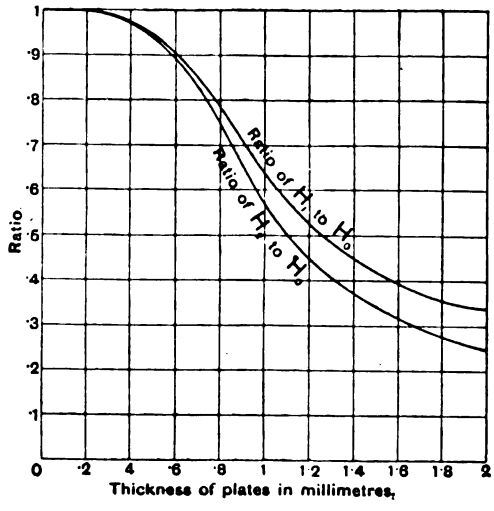

Fig. 3.—Magnetisation of plates of various thicknesses by alternating forces.

Fig. 3 gives values of the mean maximum amplitude H_1 and the maximum mean amplitude H_2 for plates of various thicknesses.

A convenient way of expressing these results as to magnetic screening is to give what I shall call the "equivalent depth of unform magnetisation." That is to say, the depth of an imaginary skin, which if magnetised uniformly with the full value of H_0 would contain the same total number of lines of force as the actual plate, with its varying distribution, does contain at that instant of each period in which the number is a maximum. The equivalent depth of uniform magnetisation on each side of the plate is equal to the maximum number of lines on either half of the plate divided by H_0.

Denoting it by b we have

$$b = \frac{a H_2}{H_0};$$

or, directly,

$$b = \frac{1}{m\sqrt{2}}\left(\frac{\cosh 2ma - \cos 2ma}{\cosh 2ma + \cos 2ma}\right)^{\frac{1}{2}}$$

The values of this quantity for plates of different thicknesses are stated below.

Thickness of plate in millimetres.	Equivalent depth of uniform magnetisation on each side (frequency 100).
	Millimetres.
Infinite.	0·252
2	0·250
1·5	0·256
1	0·282
0·75	0·285
0·5	0·233
0·25	0·1245

It will be seen from these figures that when alternating magnetic forces are applied to thick iron plates with a frequency of 100 the total magnetisation is substantially the same as if the plate consisted of two skins, each one quarter of a millimetre thick, with an empty space between. It is only when we make the total thickness less than the sum of two such skins that any very marked falling off begins to be seen in the total quantity of magnetisation in the plate.

Turning now to the losses by eddy currents and by hysteresis, we have seen how E, the loss by eddy currents, is calculated, and values of $\frac{E}{H_0^2}$ have been given in the table, for various thicknesses of plates, the frequency being 100. For most purposes what we chiefly wish to know is how E depends on the thickness of the plate, not under constant value of H_0, but when the mean magnetisation is forced up in the thick plates to the same value as it is in the thin plates. In other words, in comparing values of $\frac{E}{H_0^2}$ for different plates we are to take, for each thickness, that value of H_0 which is required to make H_2 the same in all, in order that the effective magnetisation may be the same in all.

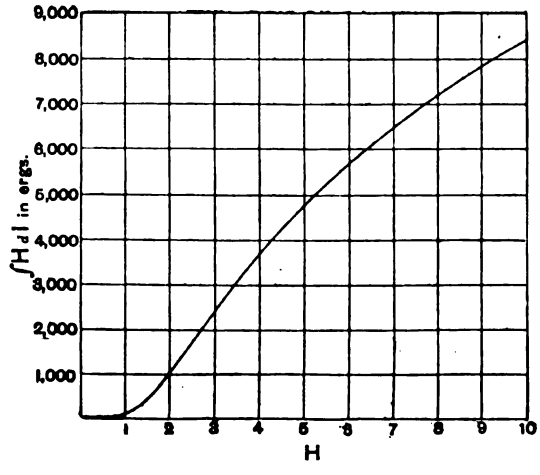

Fig. 4.—Loss due to hysteresis, per cycle, for various values of H, in the sheet iron of Fig. 1.

For example, let it be supposed that we are to work with a *mean* amplitude of induction B of 4,000. In plates which are indefinitely thin, this would require H_0 to be 2 (since $\mu = 2{,}000$). To force the same mean induction through thicker plates, H_0 has to be increased in the ratio $\frac{H_0}{H_2}$. Thus in plates ¼mm. thick, H_0 would have to be only very slightly greater, namely 2·01 ; in plates ½mm. thick it would have to be 2·15, in plates 1 mm. thick 3·55, and in plates 2 mm. thick it would have to be 8 (if the permeability could be still treated as nearly constant at so high a value of H).

The hysteresis loss depends upon the mean amplitude of magnetic force, which we have denoted by H_1. I find by recent experiments in which sheet iron cores were carried through slow cycles of magnetisation, that a very simple empirical formula serves well to express the relation of hysteresis loss per cycle, or $\int H\,dI$, to the amplitude of the magnetic force, throughout the range of induction which is common in transformers. Fig. 4 shows what appears to be a representative

Digitized by Google

case, it relates to the same sheet iron as fig. 1. From $B = 2{,}000$ or even less, up to 8,000 the curve of $\int H\,dI$ and H is very nearly a straight line (not passing through the origin); and within these limits the formula

$$\int H\,dI = 1340\,H - 1610$$

seems very well to express the work done per cycle in ergs per cubic cm. By using H_1, which is the mean amplitude of H across the plate, we may at once apply this formula to find the hysteresis loss in plates of various thicknesses. For instance, in a plate 1 mm. thick, if the induction is to be 4,000, we have seen that (for a frequency of 100) H_0 must be 3·55. Hence H_1, which by the table is equal to 0·629 H_0, is 2·23, and the value of $\int H\,dI$ for a cycle is $1340 \times 2{\cdot}23 - 1610$, or 1380 ergs. Thus the hysteresis loss per cubic cm. per second is 138,000 ergs. We have already seen that the eddy-current loss per cubic cm. per second in a plate of this thickness is $19{,}140 \times H_0^2$ or 241,200 ergs. Thus in this case the loss due directly to eddy-currents is larger than that due to hysteresis.

Proceeding in this way I have calculated the following figures for the losses due to eddy currents and to hysteresis in plates of various thicknesses, when the induction has certain assigned values. All these calculations, it is to be remembered, relate to an assumed frequency of 100.

Plates ¼mm. thick.

Mean amplitude of induction B.	Eddy current loss per cub. cm. per second. Ergs.	Hysteresis loss per cub. cm. per second. Ergs.	Total loss per cub. cm. per second. Ergs.
4,000	16,500	107,000	123,500
6,000	37,000	241,000	278,000
8,000	66,000	375,000	441,000

Plates ½mm. thick.

Mean amplitude of induction B.	Eddy current loss per cub. cm. per second. Ergs.	Hysteresis loss per cub. cm. per second. Ergs.	Total loss per cub. cm. per second. Ergs.
4,000	66,000	110,000	176,000
6,000	147,000	245,000	392,000
8,000	262,000	379,000	641,000

Plates of various thicknesses, when B = 4,000.

Thickness (millimetres)	H_0	H_1	Eddy current loss per cub. cm. per second. Ergs.	Hysteresis loss per cub. cm. per second. Ergs.	Total loss per cub. cm. per second. Ergs.
2	8	2·74	569,000	206,000	775,000
1·5	5·87	2·46	427,000	169,000	596,000
1	3·55	2·23	241,000	138,000	379,000
0·5	2·15	2·02	66,000	110,000	176,000
0·25	2·01	2·00	16,500	107,000	123,500

These last results are also shown in Fig. 5, where curves are drawn to exhibit the two kinds of loss, and also the sum of them, in relation to the thickness of the plates. It is interesting to notice how, with the assumed frequency of 100, any thickness greater than ¼mm. causes the losses by eddy currents to become important. So long as the thickness does not exceed ¼mm. nearly the whole loss is due to hysteresis. But even when the thickness is no more than half a millimetre, the eddy current loss forms more than one-third of the whole loss; and in thick plates it greatly exceeds the other. Further it is to be noticed how the loss by hysteresis increases slowly as the thickness of the plate is increased. This is an indirect effect of magnetic screening, alluded to at the beginning of this Paper. Though the average amplitude of magnetisation is kept constant the hysteresis loss is not constant, it is increased in consequence of the inequality of the magnetisation.

As to the practical question of the degree to which lamination ought to be carried in the magnetic circuit of a transformer, two things are to be considered: first, what thinness will suffice to avoid serious magnetic screening; and, next, what thinness will suffice to avoid serious eddy current losses. From the number and figures which have been given it will be clear

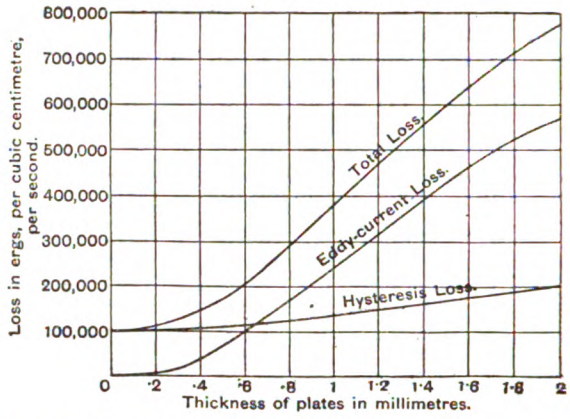

Fig. 5.—Losses due to eddy currents and hysteresis in sheet iron plates, when B = 4,000, and frequency = 100.

that the magnetic screening ceases to be serious when the thickness is reduced to ½mm., and, so far as uniformity of magnetisation is concerned, there is little advantage in laminating further than that. But when we come to consider eddy currents we see that a greater amount of lamination is desirable to prevent the eddies from causing a serious addition to the loss which hysteresis makes inevitable. Fig. 5 shows that the thickness should be reduced to something more like ¼mm. On the other hand, to reduce the thickness to less than ¼mm. would be useless (unless the frequency were very considerably increased) and worse than useless, inasmuch as the non-magnetic space in the core would be needlessly increased.

These conclusions justify what I understand to be the present practice of good makers of transformers in using plates the thickness of which is only about 0·014in. or 0·35mm.

NOTES ON SUBMARINE CABLE WORK.

BY H. D. WILKINSON.

(*Continued from page 566.*)

7. Picking Up.—The ship now starts picking up cable towards the fault, the main engines being kept moving easy ahead in order to keep the ship's head to the cable and relieve the strain on the picking-up engine. The cable comes in at the rate of about one or two miles an hour in deep water, a six-foot winding-drum being slowly driven at about 10 revolutions per minute. The steam engine used for driving the picking-up gear runs at about 150 revolutions per minute, the power being transmitted from the engine to the drum shaft through spur gear on two or more intermediate shafts, by means of which the speed is reduced. The length of cable hauled inboard can be ascertained at any moment from the indications of a revolution counter or rotometer, which records the total number of revolutions made by the winding-in drum. One form of rotometer, contained in a brass box about 1½in. square by 6in. long, consists of a set of discs, each with ten figures on the rim, which show themselves in succession through holes in the cover of the instrument as the impulses are given. By a simple gear between the discs they are made to indicate units, tens, hundreds, thousands, and tens of thousands of revolutions. An impulse is given every revolution by the lever C (Fig. 25) jointed to the lever L, which is lifted for a short period of every revolution by the pin *p* projecting from the side of one of the wheels on the winding-drum shaft. The rotometer box is fixed in any convenient position for reading as at S, supported by the bracket M. A note is taken of the figures as they stand before the cable end first winds round the drum; and the difference between this number and that observed at any

Digitized by Google

subsequent period is the number of revolutions made. This multiplied by the circumference of the drum in feet and divided by 6,087 gives the length in knots of cable picked up, and is entered in the Electrician's log in knots and fractions of a knot to three places of decimals.

After the cable passes the picking-up drum it is coiled into one of the tanks on board. If the cable has to be coiled in the fore tank it is simply passed from the picking-up drum direct through a ring in the cable hatch, and down into the tank; but if to go in any tank aft, a number of V sheaves are placed in convenient positions along the deck as guides, over which the cable rides to the required tank. The ring or dead-eye, which is fixed to timbers over the centre of each hatchway, is placed horizontally, so that the cable threads straight down through it into the centre of the tank, the edges of the ring being bell-mouthed out above and below for the cable to run smoothly through.

Some ships carry two tanks forward of the engine-room and one aft, while others carry four, the tanks varying in size according to the tonnage of the ship. The average gross tonnage of cable-repairing ships for deep-sea work is from 1,000 to 1,500 tons, but many are smaller than this. There are about twelve cable ships in different parts of the world, whose respective gross tonnage varies from 300 to 1,000 tons. The very large vessels of gross tonnage ranging from 2,000 to 5,000 tons are owned by cable-manufacturing companies, the great advantage of their size being that in laying new cables, the capacity of the tanks is sufficient to permit of the ship taking

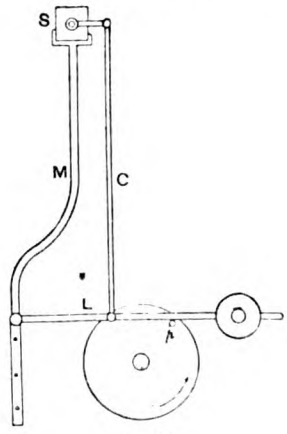

Fig. 25.

out from 1,000 to 2,000 miles of cable in one trip. Considerable space and accommodation on board is also required for the cable hut material, stores, testing instruments, and staff destined for shore work while the ship is laying cable. Of these large vessels there are five, namely, the "Silvertown," of 4,935 tons (one of the four ships owned by the India-Rubber, Gutta Percha and Telegraph Works Company), the "Faraday," of 4,916 tons, owned by Messrs. Siemens Brothers and Co., and the "Scotia," of 4,667 tons, the "Seine," of 3,553 tons, and the "Calabria," of 3,321 tons, owned by the Telegraph Construction and Maintenance Company.

As mentioned above, steamers for deep-sea work designed for repairing purposes only, and therefore not required to carry great lengths of cable, have, on the average, a gross tonnage somewhere between 1,000 and 1,500 tons. Such vessels are usually fitted with four tanks, which are numbered consecutively, commencing from the one nearest the bows. In several of these ships, No. 1 tank is about 14ft. diameter, No. 2, 25ft., and Nos. 3 and 4 about 16ft. or 17ft. The two first are built on the water-ballast tanks forward of the engine room; the largest, No. 2, being about 12ft. deep, and the top reaching very nearly to the level of the main deck. The tank is entered by going down to the lower deck, climbing up over the edge of the tank, and then descending by the foot pockets. If the tank contains many lengths of cable there will be a number of ends sticking out above the top, and lashed to the side of the tank in a convenient position for connecting on leads to the testing room. Both ends of each length of cable are secured in this way, so that in testing any given length both ends may be used, or one end freed or earthed, the earth used being the outside sheathing wires of the cable. The ends of each length are labelled, and marked with the type of cable and the length coiled in.

Cable is always coiled from the outside of a tank inwards, and as it cannot be coiled right to the very centre of the tank, a hollow cone, about 6ft. diameter at the bottom, and tapering up to 3ft. at the top, is placed in the centre of each tank. These serve to keep in position the several turns of cable composing each flake, and are otherwise put to use in holding fresh water.

Fig. 26.

Inside the tank, while cable is coming on board, a number of men, varying from six to twelve according to the size of the tank, are employed at coiling. One man runs round and round the tank, keeping up his pace at the rate the cable comes in, and pushing it outwards towards the remainder of the men, who are stationed round the tank at equal distances. As the cable passes each man he seizes it and lays it down close to the last turn, so that the coils

Digitized by Google

are kept regular, and kinks avoided. Native seamen, who are chiefly employed as crew on cable ships abroad, do this work very well, singing or yelling in their own way while doing it, their voices reverberating again and again in the large hollow tanks, and producing a strange medley of sound.

While picking up cable, especially if it has been somewhat buried, and not touched for a number of years, it comes up covered in many places with beautiful deep-sea growths, the roots having got a very firm all-round grip of the cable. The appearance of these as the cable emerges from the water is that of ferns of delicate tracery spread out like fans, and shining with colour, either green, brown, or red. As the cable passes over the bow sheaves most of these are crushed out of shape, but some pass unhurt. The writer collected some specimens of these growths while engaged on the repair of the cable between Singapore and Saigon some years ago, and has endeavoured to give some idea of their formation by the sketches in Fig. 26. Two of these (*Gorgonidæ Menacella Sp.* and *Plexaura Flabellum*) measure 19in. × 15in., and are fan-shaped; the other (*Gorgonidæ Engorgia Nobilis*) is a smaller specimen of a deep red colour. In some instances these are covered over by Polyzoa. The cable in question had not been touched for several years, and was deeply imbedded in mud at the time of picking up.

(To be continued.)

THE CHEMICAL AND PHYSICAL PROPERTIES OF ROSIN OIL.

Until recently it was generally believed that the use of rosin oil was almost entirely confined to the manufacture of printing inks and cart grease, and the adulteration of other and more expensive oils. Although large quantities of it were manufactured, but little found its way into the retail market, at least under its own name. There is now, however, some probability of an increased consumption taking place owing to the rediscovery of its properties as an insulator; and it will not, therefore, be out of place to say something concerning its nature and properties, if only to dispel the vague atmosphere with which the subject has been surrounded, and to show how completely any dogmatic statements that have been made, or may be made, must be modified by a consideration of the quality of the oil referred to.

In the first place, rosin oil is so called because it is the heavier part of the products of the destructive distillation of rosin, which, in its turn, is the residue left by distilling crude turpentine, spirits of turpentine being the volatile portion. The ordinary vitreous body, varying in colour from light yellow to almost black, known as rosin, consists of a mixture of abietic acid and abietic anhydride, together with a small quantity of sylvic acid. When distilled, these bodies are broken up, yielding a mixture of hydrocarbons, accompanied by a larger or smaller proportion of unchanged rosin acids and anhydrides. The relative amount of these constituents is determined by the design of the stills and the manner in which the distillation is conducted. The more carefully prepared and refined the oil is the lower is the proportion of rosin acids, and in the laboratory rosin oil may be obtained with but a few per cent. of substances other than hydro-carbons. The specific gravity of rosin oil of commercial quality may vary from 0·98 to 1·10, while its power of rotating a beam of polarised light is similarly variable, being generally dextro-rotatory, but sometimes lævo rotatory, or nearly absent. These facts are sufficient to indicate the variable character of commercial rosin oil, and the futility of discussing its electrical properties without defining the character of the sample used is tolerably apparent. In the various communications which have lately been made concerning rosin oil insulation, this necessity has not been sufficiently kept in sight. The only satisfactory method of settling once for all the kind of oil best fitted for this purpose would be to examine the insulating capabilities of numerous samples, and simultaneously determine their composition by analysis. If this were done and it were ultimately found that rosin oil could be as advantageously used as some of its advocates appear to think, there would be afterwards no difficulty in obtaining supplies of precisely the same quality as those which had been found efficient. The maker would be given a definite standard to work to, and could, by the aid of his chemist, match that standard as nearly as would be necessary.

In dealing with rosin oil, one of the most noteworthy qualities that are apparent on inspection is its great viscidity. It is to this, and to its immiscibility with water, that its applicability for the purposes of insulation is chiefly due. It is, therefore, plain that in addition to a purely chemical examination, the determination of the important physical property of viscosity would have to be undertaken. Thanks to the advances that have been made in the methods of examining lubricating oils, there is no difficulty in effecting this. Besides determining the viscosity at ordinary temperatures, it would be very desirable to do so at higher temperatures, as it by no means follows that oils of the same viscosity at any given temperature have the same coefficient of decrease as the temperature is raised. There is a further point which seems to have been also overlooked. Rosin oil when exposed to air undergoes change. How noteworthy that change may be has been opportunely illustrated by some figures given in a Paper by Mr. F. H. Leeds, which was recently read before the Society of Chemical Industry. The results of three of the samples examined are given below:—

No. of sample.	Original oil.		Oil after exposure to air.	
	Rosin acids.	Hydrocarbons.	Rosin acids.	Hydrocarbons.
A	31·07	68·93	24·90	75·10
B	22·20	77·80	16·09	83·91
C	9·72	90·28	4·29	95·79

The results show that a considerable amount of alteration has taken place. There is an apparent decrease under the column headed rosin acids (which strictly means total saponifiable matter, including probably anhydrides and esters), and an increase under the head of hydrocarbons. It is unlikely, on purely chemical grounds, that a conversion of the former into the latter takes place. Probably the explanation of the change is to be sought in the volatalisation of the lighter acid constituents, and the consequent enrichment of the mass in heavy non-volatile hydrocarbons. In the Paper in which these results appear, other differences are recorded and discussed, but, being at present still unsettled, do not immediately concern us. One deduction is, however, plain, namely, that an oil may undergo profound alteration by exposure, and may well alter in character to such an extent as to become more or less useful in tangible degree. It can, therefore, never be safe to assume that, because a specimen of oil has at one time given certain results, it will necessarily possess identical properties after the lapse of time, particularly if the conditions under which it has been kept have involved its exposure to the atmosphere. This again opens up a field for investigation, in that not only do all kinds of rosin oil change, but that the tendency of oils of different qualities to alter by exposure varies greatly. It is probable that samples consisting almost wholly of hydrocarbons would prove the most resistant, and, if found to be also high in insulating power, would be preferable on that account. Direct experiment is, however, much needed.

ELECTROPLATING WITH SILVER ALLOYS.

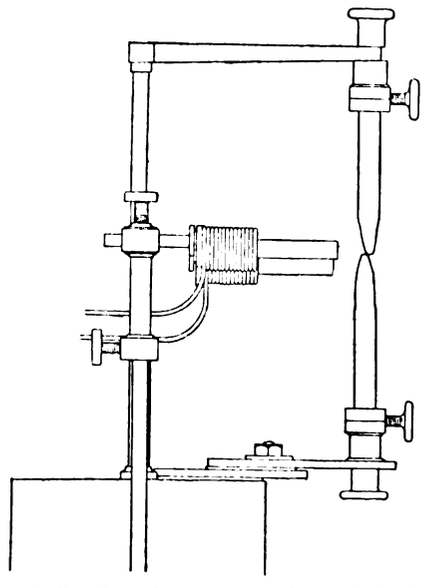
Some time ago we published a Note upon the method of electroplating called "Arcas Plating." The earlier samples of this product, to which, being then a secret, we did not give much attention, consisted of an alloy of zinc and silver, containing about 10 per cent. of the former metal, and the property which distinguished it from ordinary plating was its resistance to those tarnishing influences which affect silver. An alteration in the method has been lately made, and the alloy now deposited is one of cadmium and silver, or of zinc, cadmium and silver. The percentage of cadmium used is from 25 to 35 per cent., although for common work a much larger proportion of the cheaper metal may be employed. The bath is made by dissolving cadmium cyanide in a solution of potassium cyanide, and adding a small quantity of the double cyanide of potassium and silver. The anode consists of an alloy of cadmium and silver of about the same composition as

Digitized by Google

the deposit required. The bath is worked cold, and the electrodes are kept in motion in order to prevent the formation of layers in solution of different densities. For this purpose the plates are carried on a frame, to which motion is communicated from a shaft running parallel to the end of the bath, by means of a rod and eccentric, and at the same time a vertical movement is obtained by causing the frame to ride up short inclined planes placed at the side of the bath. The alloy can be deposited on such metals as form a suitable substratum for silver plating, either direct upon white metal alloys, or on a previously-coppered surface in the case of iron. A weight of 1oz. to the square foot gives a good coating, and, like the original alloy there is said to be less tendency to tarnish than when silver alone is used. Greater current density can also be adopted, so that a given tank will turn out about twice as much work as when silver plating is being done. A curious phenomenon has been noticed in rolling the metal for anodes. When the proportion for cadmium slightly exceeds 35 per cent., the plate shows a tendency to split longitudinally into strips of triangular section, the bases and apices of which alternate on each side of the plate. No explanation, as far as we are aware, has been advanced to account for this effect, which certainly merits investigation. The process as a whole is chiefly interesting from the fact that it adds another to the scanty list of those in which an alloy is successfully deposited. It may be that in time alloys will hold as useful a position in commercial electrolysis as they already do in other industrial arts.

THE PECKHAM ARC REGULATOR.

For a year and more past, says Mr. W. C. Peckham, in the *Electrical World*, I have been using upon the arc lamp in my lantern a device to hold the arc in a fixed position in the front of the carbons, which works very successfully.



Peckham's Regulator for use on Arc Lamps in Projectors.

The device consists of an electro-magnet, wound with a few turns of No. 12 insulated copper wire in series with the lamp. The cores project (see Fig.) about 1½in. beyond the coils, so that these are set back beyond the great heat of the arc, which would destroy their insulation. An asbestos covering would still further protect them, if necessary. The wires are connected so that both poles drive the arc toward the farther, or front, side of the carbons. Wherever it is desirable to hold the arc in a definite position this regulator has value. It can easily be attached to any form of lamp, focussing, or search light.

The illustration shows the lamp with regulator in position. It is secured in the same plane with the focus of the condenser and the axis of the lenses. The regulator is attached to the base of the lamp, and does not move when the carbons are adjusted to focus, as they burn down.

ON THE UTILISATION OF THE WASTE FORCES OF NATURE.*

BY W. H. PREECE, F.R.S.

The sun is the *fons et origo* of all the available energy upon the surface of our earth. Countless ages ago its warm and vivifying rays promoted the growth of plants and ferns and trees, which, falling where they grew, formed those great beds of coal now being brought to the surface, and which, combining with the oxygen of the air, provide us with heat and power to supply our wants, to maintain our manufactures, and to expedite our locomotion. These same rays are now in a similar way hastening the growth of trees and making wood, the difference between wood and coal as fuel being only age. They are now also furthering the annual growth of grasses, corn, fruits and vegetables to become food for beast and for man, and to supply them with fuel to maintain their life, their strength, and their capacity for work. The same rays playing on the surface of the waters promote the evaporation of the liquid into gas, which, mixing invisibly with the air, gives evidence of its presence when the lowering of temperature causes its condensation into the floating clouds and its ultimate return into the waters in the form of the gentle rain, the rippling brook, the roaring torrent, or the flowing river. The sun's rays, again, produce that variation of temperature in our atmosphere leading to currents of air which sometimes fan our faces with cool and refreshing breezes, and at other times rage and roar with the relentless fury of a tornado. The sun, together with the moon, so attracts the mobile waters of the ocean that it produces great periodic waves and currents known as the tide, which ebbs and flows with such uniformity and regularity that we can calculate the rise and fall of the water at any particular spot, and its rate of flow, not only at the present day, but for any future time, provided the geographical conformation of the land and the bottom of the sea remain unaltered.

Coal and oil pent up in the bowels of the earth and water accumulated in the higher levels of the land are our great stores of energy, available for the wants and purposes of man. The wind, the running streams, and the flowing tide are the passing forms of energy which are available for our present use, while food is the particular form of fuel which maintains life and provides the means of doing work. These are all natural sources of energy; while gunpowder, gas, compressed air, steam, chemical affinity, &c., are artificial sources which the ingenuity of man has fashioned for his use.

In that interesting work of Smiles, "The Story of the Life of George Stephenson," we read: "One Sunday, when the party had just returned from church, they were standing together on the terrace near the Hall, and observed in the distance a railway train flashing along, throwing behind it a long line of white steam. 'Now, Buckland,' said Mr. Stephenson, 'I have a poser for you; can you tell me what is the power that is driving that train?' 'Well,' said the other, 'I suppose it is one of your big engines.' 'But what drives the engine?' 'Oh, very likely a canny Newcastle driver.' 'What do you say to the light of the sun?' 'How can that be?' asked the doctor. 'It is nothing else,' said the engineer; 'it is light bottled up in the earth for tens of thousands of years—light, absorbed by plants and vegetables, being necessary for the condensation of carbon during the process of their growth, if it be not carbon in another form; and now, after being buried in the earth for long ages in fields of coal, that latent light is again brought forth and liberated, made to work, as in that locomotive, for great human purposes.' The idea was certainly a most striking and original one; like a flash of light it illuminated, in an instant, an entire field of science."

I have used the words *work*, *energy* and *power*. *Work* is the effort exerted when we overcome resistance. When we walk upstairs we overcome the resistance due to the attraction of the earth, and we raise our bodies to a higher level. Work is thus done by ourselves on ourselves. When a train is moved from Liverpool to Warrington the friction or resistance of the

* Read before the Liverpool Welsh National Society and the Liverpool Engineering Society, April 6th, 1892.

Digitized by Google

rails is overcome as well as that due to gravity (for we go up hill). Work is thus done by the locomotive on the train of carriages. Force has been applied, resistance has been overcome through a certain distance; and this is the measure of work expended. But this capacity for doing work must exist in a dormant state both in our bodies and in the locomotive, and this is called *energy*, which is stored up in food and in fuel, energy being simply the capacity for doing work. While the work done or energy expended is measured by the distance through which resistance has been overcome and by the weight of the object moved, the *rate* at which the *energy* is expended or the amount of work done per minute or per second is the *power*. Power is, therefore, the rate of doing work. Watt called the work expended in one minute in raising 33,000lbs. (14¾ tons) one foot high a *horse power*, and this is the same as raising 550lbs. per second. A man can raise ½cwt. per foot per second for a short time. A horse dragging a cart of materials weighing one ton over a level road at a speed of four miles an hour exerts this power; and one of Mr. Webb's locomotives driving an express train over the London and North-Western Railway at sixty miles an hour may expend about 750 horse-power. Fourteen gallons of water falling four feet per second could perform about the same work as this typical. horse, and thus a horse-power becomes a very convenient, though rough and unscientific measure of the rate of expending energy.

Energy is expended when coal or wood is burnt, when water falls, when tides flow, when the winds blow, when food is digested; and the function of steam and gas-engines, of water-wheels and turbines, of windmills and of beasts of burden, is to transmit this energy to some spot where it can be utilised for the wants and purposes of man. But water is ever falling in the mountains of Wales, shining rivers flow on for ever and for ever, the tides ebb and flow daily in our straits and estuaries, the wanton winds expend their energies always over the surface of the land; and man neglects these stores of energy that Nature gives him at his very door.

Let us assume that we have at our command, at one spot, some source of energy, such as a steam-engine or a water-turbine, how can we transmit the power exerted to some other spot where it can be better utilised? Belts and shafts and ropes are at our command. A 4-in. rope, moving at a speed of 2,000ft. per minute, transmits 8 H.P. The valleys of Switzerland abound with such conveniences. We may even lead the water itself in pipes and channels, and in America they even distribute the live steam over considerable areas. Gas is a very convenient medium for the distribution of actual energy, and since the advent of the electric light its use for this purpose has been very largely encouraged. In the United States it is found in a natural state underground, and it is being conveyed to distances of even 100 miles.

Compressed air is a very convenient medium for the transmission of energy. It is largely used in mines. In London it is employed for the transmission of telegrams, and in Paris it is in successful work for postal work and for a large number of industrial pursuits. 10,000 H.P. can be transmitted 20 miles in a 30-in. pipe by air at 132·3lbs. pressure, with an efficiency of about 40 per cent., that is, about 60 per cent. of the original energy is wasted or lost in transit. The efficiency of a system is the ratio of the energy utilised to the energy expended. Thus to get 1,000 H.P. at the end of a pipe 20 miles long, we must expend 2,400 H.P. at the beginning.

The common way of transporting energy is by cart, or by train, or by ship. Thus coal and wood are carried anywhere, but at a price. This also means an efficiency for the cost to the consumer is much enhanced by the carriage of the material. Coal at the pit's mouth costs 6s., in Liverpool it may cost 18s. per ton; its efficiency is thus 33 per cent. In London we have been paying 30s. per ton; the efficiency is, therefore, only 20 per cent. There is another mode of transmitting energy, and that is by the electric current. It is not my intention to occupy your time with a description of a dynamo. It must be known to most of you; Electric Exhibitions have made us familiar with the principal industrial electrical apparatus. The dynamo is an instrument designed to convert the mechanical energy of motion into the form of energy called electrical. The answer to the question, "What is electricity?" is now, "Principally coal and sometimes water." Five pounds of coal consumed per hour in a furnaceflashes 50lbs. of water into steam. The steam in its re-conversion to water transfers its energy to a moving mass of machinery, a part of which consists of copper rods forming a portion of an electric circuit. These rods rotate in a magnetic field where work is done on them, and where, in consequence, the mechanical energy of motion is converted into the molecular energy of electricity. The 5lbs. of coal have produced 1⅓ H.P., or 1,000 watts in the circuit; in fact, a kilowatt is the scientific unit of power, and a kilowatt-hour is the Board of Trade unit of energy for the use of which the Electric Lighting Company of Liverpool is allowed to charge 8d. A watt is the energy expended by an ampere when driven by a volt. It is equivalent to nearly ¾ (actually 0·737) of a footpound. The ampere is the unit current, and the volt the unit electrical pressure. A 16-candle glow lamp requires 100 volts and 0·48 ampere to incandesce it into brilliance. It therefore absorbs 48 watts and consequently 1 c.p. is produced by 3 watts. Hence, a kilowatt-hour uniformly expended will give us 333 candles continuously, or it will maintain 21 such lamps alight. But this kilowatt of energy need not have given us light; it could have been converted into other forms of energy; it could be used for electro-metallurgical purposes; it could deposit copper; it could produce aluminium; it could break up salt solution into chlorine and caustic soda; it could silver our plate and gild our cups; it could be re-converted into mechanical energy by electric motors; and could again drive machinery, turning mangles, knife-cleaning machines and ventilators in our dwellings, sewing machines in our shops, blowing organs in our churches, driving tramcars on our streets and trains on our railways. Again, it could give us heat, warming our rooms, heating our irons, and, as we see every day in the Crystal Palace, boiling our water and cooking our food.

I am anxious to attract your attention especially to the facility which the electric current gives us to bring power to our doors and to enable us to facilitate home industries. The congregation of large bodies of males and females in magnificent buildings is a modern consequence of great industries dependent on the presence of great power and great steam-engines. A system of centralisation has followed, which is not always beneficial to healthy mental and corporeal growth. The electric current steps in to check this system. It enables us to apply in our own dwellings power from the smallest fraction of a horse-power to many hundred horse-powers.

Moving water as a source of power is already utilised to a very large extent. At Bushmills, near the Giant's Causeway in Ireland, there is a fall of 26ft., which, actuating turbines, produces currents of electricity that drive a railway from Portrush, a length of six miles. This line has been at work since 1883. Between Newry and Bessbrook, also in Ireland, there is another railway worked electrically, in the same way and of the same length. At Lynton, in Devonshire, and at Keswick, in Westmoreland, the fall of water is used for electrically lighting the two places; while at Tivoli, near Rome, 2,000 H.P. is going to be converted into electrical energy which will be transported 18 miles to Rome to light up 40,000 lamps. At Geneva the lake which merges there into the river Rhone flows through the town with considerable velocity, and more than 3,000 H.P. is there obtained, not only for electric lighting purposes, but to raise water to a height of over 400 feet, so as to distribute its energy over the whole town for the innumerable watch, musical box and other industrial purposes for which that town is so famous. At Schaffhausen (the famous falls of the Rhine) about 600 H.P. is converted into electrical energy, and is applied to the production of aluminium, and 700 H.P. for the transmission of power to a woollen spinning mill about half a mile away, the wires crossing the river. At the Skippers Creek Mountains, near Otago, in New Zealand, two 50 H.P. turbines generate electrical energy, which is transmitted three miles to work quartz stampers. At the Virginius mines in Colorado some unprofitable mines at a height of 12,700 feet have been made profitable by the utilisation of water at the foot of the mountain. Labour has also been reduced. Two pumps, a hoist, a blower, and two mills

Digitized by Google

are worked by electric motors, 1,200 H.P. being available for transmission four miles up the mountain by current.

The economy of the transmission of energy by electricity is a question of pressure. The higher the voltage (pressure), the smaller the conductor needed, and the greater the distance to which it is possible to transmit the energy. It is difficult to obtain high voltages except through the aid of alternate currents and by means of induction apparatus which transform low to higher pressure. The apparatus for doing so is extremely simple and effective. The Ferranti apparatus in Deptford generates 10,000 volts directly by a dynamo which drives currents eight miles to London, and is there re-transformed down first to 2,400 and then to 100 volts for electric lighting purposes. At Lauffen, on the Neckar, a turbine worked by the falls there absorbing 300 H.P. with a head of 10ft. excited a dynamo to 50 volts and 4,000 amperes. These low-pressure currents passed through a transformer which raised the voltage to 16,000 volts. Three small bare overhead copper wires (No. 8 gauge), insulated on oil insulators, conveyed this energy to Frankfort, 108 miles away, where it was transformed down to 75 volts, and there used both for motor and for lighting purposes. The apparatus worked during the existence of the Frankfort Exhibition last year, and it is now employed in lighting electrically the town of Heilbronn, nine miles distant from the falls, but at a pressure of 5,000 volts. The peculiar feature of this Lauffen system is the use of three wires and three alternating currents, one in each wire, flowing at different phases, following each other like the relative motions of the three cranks of a three-cylinder steam-engine, or of a three-throw pump. This "Drehstrom" cures all the defects of alternating motors; it causes no disturbance to contiguous telephones and telegraphs; it is sparkless and safe, and the apparatus is remarkable for its simplicity. The system has been practically worked out by Tesla in the United States of America, and by Dobrovolski in Berlin. It solves the question of economically transmitting energy to great distances. Coal may be burnt at the pit's mouth, and 75 per cent. of its useful electrical energy delivered in London. The energy of the Swallow waterfall at Bettws-y-Coed may light up the streets of Liverpool. The foaming torrents of the Highlands can be made to drive the tramcars of Glasgow. It is proposed to transmit energy by this method from Niagara to Chicago next year—a distance of 500 miles—and this can certainly be done with a voltage of about 40,000 volts, and with an efficiency of about 60 per cent.: 5,000 H.P. generated at Niagara would deliver 3,000 H.P. at Chicago. The principal cost of the system lies in the construction and upkeep of the wires; the cost of the plant is small and the labour insignificant. It remains to be seen how the relative economy of coal carriage and energy transmission will affect this great industrial question. Anyway we may conclude that the experiment at Frankfort has practically solved the question of transmitting energy to a distance and of working motors by alternating currents.

How, then, are we to utilise the waste forces of Nature?

The sun's rays pouring on the desert of Sahara are generating the equivalent of millions of horse-power in the heat absorbed by that great sandy waste. Sunshine is power. Coal is merely preserved sunbeams. The solar heat acting on one acre in the tropics would, if it were possible to utilise it, produce 4,000 H.P. for nine hours every day. To utilise this heat is not a mere dream; it is certainly possible to convert it into electrical energy by thermo-electric apparatus, though I have not yet heard of its being done.

The earth itself in its daily rotation round its axis is an immense store of energy. If we could by any means reduce a little of this spin we should lengthen the day, but we should obtain energy. Mr. Gisbert Kapp has calculated that if the day increased only one second 100 years hence we should during the whole of this century obtain 10,000,000 H.P. continuously. There is no doubt that the tidal wave is gradually acting upon the earth's spin in this way, but the energy is not available for man, and it is one of our wasted energies.

The tides of the ocean, surging backwards and forwards with unerring accuracy, produce in our estuaries and straits movements of great masses of water which, if utilised as power, could be turned to useful account. Take the case of the Menai Straits, whose breadth at Belan, the entrance from Carnarvon Bay, is 1,188ft., and mean depth about 50ft. This gives a sectional area of water of approximately 60,000 sq. ft., flowing either in or out four times a day at a mean speed of 3 knots per hour, which gives a velocity of 5ft. per second. The effective energy of such a stream would give 6,000 H.P. if it could be utilised. At the present moment not one fraction of this wasted power is employed other than for the motion of ships and boats. The total tidal area of the estuary within the mouth of the River Mersey at New Brighton is 22,500 acres. The mean total volume of tidal water passing in or out of the estuary four times a day is 4,455 million cubic feet. The mean rise or fall of the water above tide level is 10½ft.; that is, the mean vertical range of the tide at Liverpool is 21ft., reaching 31ft. on equinoctial springs and 10ft. on lowest neaps. This would give an available power of about 100,000 horses, if it could be utilised; but this is of course an impossibility. In some estuaries the flood tide is caught by dams in a kind of dock and made to work mills in its ebb, but with a rise and fall of 6ft. it requires a dock area of 10 acres to give 20 H.P. But tide mills are very expensive in their prime cost, and they are rarely resorted to unless Nature has favoured their use by unusually high tides or by convenient geographical configuration. The power executed by tidal rivers is much less than is usually considered. The total tidal energy of the Thames at London Bridge is 320 H.P., from which we could not extract usefully more than 100 H.P., and that only by stopping the whole navigation of the river. The available energy passing through one archway is only 20 H.P. The total available energy of a slow shallow tidal river like the Thames is therefore comparatively small, and its inconvenience would be so great that it is not worth consideration. It is different with a constant flowing river. In a constant moving mass of water the work done per second by the stream depends on the pressure exerted by the water on the effective float area exposed to the stream, and on the rate at which the water flows. The whole energy of a stream running at 5ft. per second (3·4 miles per hour) against a resisting float surface of 5 sq. ft., would exert approximately 1 H.P., and if the efficiency of our machinery be 50 per cent. 10 sq. ft. will give us about one effective horse-power. Hence it is not a difficult problem to utilise the energy of a current of water on a small scale, especially as the energy increases as the cube of the velocity. An extremely ingenious hydraulic motor has been devised by two young engineers, Messrs. Purdon and Walters, of Great George-street, which, moored in a stream, absorbs the energy of the moving water in a novel and effective way, and converts it directly into electrical energy. One is going to be fixed in the upper reaches of the Thames to form a charging station for electric launches. The energy of the falling river will thus be utilised to drive boats up the stream against its own resistance. The quantity of water going down the Seiont from the beautiful lake of Llanberis is approximately five million gallons per day, and it falls about 300ft. Hence the whole energy of the river, if it could be utilised, would supply a constant power of 320 horses. There are already several mills on the stream utilising some of this power; but enough remains, at any rate, to illuminate the streets of Carnarvon with the electric light. Forty million gallons of water will be daily brought to Liverpool from Lake Vyrnwy when the system is complete. The top water level of the lake is 820ft. above the level of the sea. The total energy continuously expended by the fall will therefore be about 7,000 H.P. Of course, much of this energy is expended in overcoming the friction against the sides of the aqueduct, in delivering the water into the houses of the consumers in Liverpool, and in maintaining the service, but there must be a good deal of energy wasted; and it is well worth the consideration of our water authorities whether some utilisation of this wasted energy in waterworks generally cannot be effected so as to deliver it in the form of electrical energy in our streets and buildings. The whole of the streets of Liverpool could be brilliantly lighted by the energy wasted in the Vyrnwy aqueduct.

Water as a source of energy is found where Nature has placed it, and not where it can be most conveniently used. The electrician has, however, interfered with Nature, and has enabled man to extract the otherwise wasted energy, and to lead it where he wills. The energy of moving water has not hitherto been much sought after in the United Kingdom, because coal is cheap, but now that strikes are rampant, the wise seek wind and water.

Wind is a somewhat fitful source of energy, but it has served its purpose and has done good service in the past. It is still in great request upon the ocean and in lands where coal is dear and air is cheap. It is much used for irrigation, and its energy can be stored either by raising water or by accumulating chemical energy in secondary batteries. Mr. Brush in Cleveland, U.S.A., has used a windmill to light his house, and Messrs. Carwardine and Co., in the City-road, London, utilise about 3 H.P. in this way every evening. An ordinary windmill, having four sails, in a pleasant breeze of 10 miles an hour, gives about 2 H.P.; and the small American circular mill, so much in request now, gives on the average about 1 H.P. The power exerted increases with the area exposed, and with the cube of the air velocity. A wind, blowing at the rate of 10 miles an hour, or, say, 15ft. per second, will exert such direct pressure on a sail 130 sq. ft. in area that it will drive a boat before it with the power of a horse. The largest sailing ship in the world has just been launched at Port Glasgow, which carries a sail area of 57,000 sq. ft., and has a tonnage of nearly 4,000. Such a wind would exert upon her a power equivalent to 440 H.P. Wind is, however, practically available only for small powers, and in exposed positions on land. There are, however, many places where country houses could be supplied with the comfort and luxury of the electric light if this errant force of Nature were curbed and brought under subjection.

While our wants are so readily and so cheaply supplied by our coal fields there is little chance of much attention being directed at present to other sources of energy; but with the diminution of our output, and the cranks of our labour communities, the attention of our manufacturers and of the custodians of our health, safety and comfort must be directed to those neglected energies which are now "wasting their sweetness on the desert air."

ELECTRIC METERS, MOTORS, AND MONEY MATTERS.*

BY PROF. W. E. AYRTON, F.R.S.

The Professor began his lecture by illustrating the dependence of the electrical energy obtained in a given time from an electric current, both on the strength of the current and on the electrical pressure, by comparing the current to a supply through a pipe of coloured water, to be paid for in proportion to the amount of colour supplied. The amount of colour supplied in a given time would be proportional to the product of the amount of liquid supplied in that time by the quantity of colour in every cubic foot of the solution. Similarly the amount of electrical energy supplied from an electric main in a given time would be proportional to the strength of the current by the electrical pressure, and therefore the costs should be measured in the same manner. He pointed out that the Board of Trade unit of electrical energy, the price of which in London varied from 7d. to 8d., was obtained by multiplying a coulomb (the quantity of electricity carried across any section of a conductor in a second by a current of an ampere) into a volt, the unit of electrical pressure, and then multiplying the result by the number of seconds in 1,000 hours. The Professor observed that instruments for measuring electric current, electric pressure, and electric energy were known as ammeters, voltmeters, and wattmeters respectively, the watt being the name given to the unit of electrical energy. The meters employed by the electric supply companies simply measured the number of coulombs passed through them, and should therefore be called coulomb meters. The name was not employed by these companies, who usually called these instruments electric supply meters, possibly because they had no desire to call attention to the fact that what was registered by the meter and what was charged to the consumer were two entirely different things. The quantity measured was the number of coulombs passed through the meter, while the quantity charged for was the product of this by the number of volts at which the electricity was supplied.

Two groups of lamps enclosed in glass fronted cases, showing as models of electrically-lighted houses, were then exhibited, with the same current passing through each of them, but the pressure in one many times greater than in the other. In the former case the model house was brilliantly illuminated, while only a feeble light was obtained in the second case. This was owing to the electrical energy consumed in the one at higher pressure being many times greater than the amount consumed in the other, though in a given time a coulomb meter would give the same indication for each. Thus, in order to convert the readings of a coulomb-meter into Board of Trade units, it was necessary to assume that the pressure kept up in the electric mains from a supply station remains everywhere and at all times constant. It was physically impossible to do this, and, therefore, the Board of Trade allowed a variation of pressure within the limits of 4 per cent. above and 4 per cent. below the nominal pressure, or an extreme variation of 8 per cent. The effects on the light of such a variation of 8 per cent. in the electrical pressure was shown by means of the model houses.

The Professor stated that a series of experiments had been made by himself and his students on the variation in light caused by a variation of 8 per cent. in the pressure. The experiments were confined to Edison-Swan lamps, as these were the only ones which could be used in this country while the existing patent was in force. They found that with these lamps the variation in the amount of light given was about seven times as great as the variation in the pressure; so that under the Board of Trade regulations a 16-candle lamp might vary from 12 to 20 c.p. Even larger fluctuations than this were often allowed to take place unnoticed by the consumer. It was easy to understand that a small fluctuation might pass unnoticed if the change took place slowly; but it would hardly be thought possible that the light could be reduced to half its previous amount without the change being observed.

It was greatly to the credit of the supply companies generally that the variations were usually kept well within the Board of Trade limits; but he could mention places not very far from Albemarle-street, where he was lecturing, at which the fluctuations very much exceeded these limits. He would, therefore, advise consumers to have the pressure on their house mains tested on their own account at frequent intervals. The Professor pointed out that the consumer could obtain legal redress if the variations in pressure exceeded the prescribed limits.

If 97 volt lamps were employed on a 100-volt circuit, then if the pressure fell to 97 volts, it would cause a loss in electrical energy to the consumer of 3 per cent., while if 100 volt lamps were employed, the loss would be 21 per cent. This would point to the advisability of using lamps of somewhat lower voltage than that nominally maintained on the circuit. On the other hand, if the actual pressure were higher than that for which the lamp was constructed, it would diminish the life of the lamp, and so run up the bill for replacing lamps; for the life of a lamp depended more on the maximum than on the mean pressure at which it is run, and a lamp was rapidly destroyed when the pressure was too high, just as a gun which might last a lifetime if not overcharged, might be seriously injured or destroyed by a single overcharge of powder.

The Professor then exhibited some experiments showing that the fact that any particular type of lamp had a certain definite pressure at which it would be used most economically had its exact analogue in gas illumination. Any gas burner had a certain definite pressure at which it gave the greatest amount of light for a given consumption, and, therefore, it was important to use regulators, as the gas regulations specified no maximum

* Abstract of the Friday evening discourse at the Royal Institution on April 8th.

Digitized by Google

pressure but only a minimum, and the pressure was frequently found to vary as much as 100 per cent. within 24 hours. In the case of gas lighting, the householder could regulate the pressure by means of taps, or automatically by means of regulators, while a glow lamp on a direct-current main, as on the low-pressure system of distribution, had to be full on or quite off in order to obtain the greatest economy. Though this counted in favour of gas, the Professor observed that the gas supplied in different parts of England varied greatly in quality, while no one had yet discovered any method of adulterating electricity.

The lecturer then gave the following classification of coulomb meters, illustrated by typical forms :—

The Edison Electrolytic Meter, in which electrolysis took place between a pair of zinc plates immersed in zinc sulphate, while, in order to avoid the trouble of weighing, it was made to automatically reverse the current after the passage of a known number of coulombs, and the number of reversals, was automatically registered.

The Motor Coulomb Meter, in which a rotating part revolved at a speed proportional to the current strength, as would always be the case for a motor with permanent magnets. This was illustrated by measurements made with a Gramme magneto-machine employed as a motor. The driving force was here proportional to the current, and the proportionality of the speed to the driving force was obtained by means of magnetic friction. In the Schallenberger meter it was obtained by means of wind vanes, in the Teague meter by means of a vane moving in glycerine, and in the Hartmann and Braun meter by means of a copper disc spinning between magnets. In the case of purely magnetic friction the smallest force would start motion, and with a large force the speed would not be very great, while with mechanical friction a certain limiting driving force had to be attained before motion would begin, after which the speed increased rapidly with the force. This was illustrated by means of a disc of copper spinning between the poles of an electro magnet in one case, and rubbing against a spring in the second case. This showed that mechanical and magnetic friction follow different laws. In either case, however, rise of temperature, and also wear, and the accumulation of dirt would diminish the speed of the motor, which might account for the fact that motor meters were not in favour with the electrical supply companies.

Periodic Meters.—In these the current was cut off at intervals for a length of time, depending on the strength of the current. The Professor had set some students to find how much unrecorded energy they could get from a Frager's meter, which is of this type, by suitably timing the opening and closing of a switch, with the result that the energy obtained was between 300 and 400 times the amount recorded ; these, again, therefore, would be unlikely to obtain favour with the supply companies.

Ayrton and Perry Meter.—This meter consisted of two clocks, one of which was an ordinary timekeeper, while the pendulum of the second clock carried a coil, while a second coil was placed underneath the bob, and the current passed through both coils in the same direction. The attraction between the two coils caused this clock to lose time relatively to the other, and it was found that if the attraction did not exceed a certain definite fraction of the weight of the bob, the difference in time was proportional to the number of coulombs which had passed through the meter. They had proposed that one clock only should be contained in each meter, and its time compared with that indicated by a reliable standard watch carried by the Inspector. Aron, in his instrument, which was constructed on the same principle, preferred to have the pair of clocks in each meter. The Professor explained that this meter had been modified to record electrical energy, instead of coulombs, and stated that the Thomson-Houston Company were now constructing an improved form of it. Another form was constructed by Messrs. Richard Frères, but all the supply companies continued to use mere coulomb meters.

Great difficulty had been experienced in making coulomb meters to register as accurately as gas meters, much of the abuse of which he considered to be undeserved, and due probably to the waste caused by the variations in pressure, but these efforts had at last been crowned with success.

Passing on to the question of heating by electricity the Professor observed that at first sight it would seem that it could not possibly be economical, as the amount of energy equal to that contained in a Board of Trade unit costing 7d. or 8d. could be obtained by burning about a farthing's worth of coal. On the other hand, however, the electrically generated heat could be applied exactly where it was wanted with a minimum of waste, and a joint could be roasted without nearly roasting the cook as well, which was decidedly wasteful. Mrs. Ayrton and the Professor's students had made a number of experiments. One of the results obtained was that it cost about 2d. an hour to maintain an ordinary flat iron at the proper temperature by means of a zigzag of insulated wire embedded in its face. If this were considered high, there was the set-off of the rapidity and ease with which it could be heated at short notice, the constancy of temperature attained, and absence of waste of time in taking it to and from the fire. A frying-pan constructed on the same principle was raised to the temperature required to frizzle butter by the expenditure of 6·84 watt-hours, which at 7d. per Board of Trade unit would cost about a fifth of a penny. An omelette could be made in this frying-pan in about a minute and a-half at about the same cost. These results seemed to show that electrical heating for occasional purposes was decidedly worthy of consideration.

LOAD DIAGRAMS OF ELECTRIC TRAMWAYS, AND THE COST OF ELECTRIC TRACTION.*

DISCUSSION.

AUTHORISED ABSTRACT.—APRIL 9, 1892.

Mr. ALBION T. SNELL had had some experience of tramway working in England, and considered that its success in the end was assured. Whether the final system would be an accumulator conduit or trolley one, he considered as yet uncertain. The accumulator car load diagram showed the current required by one car only, and there were numerous cases of no current when running down hill or stopping, whereas the trolley diagram referred to several cars ; and so the periods of no current were shorter, and there were less variations of current. The crux of the accumulator system lay in the accumulators themselves. On the Barking line there were four cars, which ran 220 miles per day. Each car had three fresh sets of accumulators daily, and in bad weather four. The charging dynamo ran from 10 to 12 hours, and gave on the average 450 E.H.P. hours per day. The energy given to the motors was not easy to determine, as the cells were sometimes run in series, and at other times in two parallels, depending on the number of passengers and the state of the roads. The drivers were always told to start in parallel, and not to work in series if it could be avoided. He estimated that the power averaged about 1 E.H.P. hour per car mile, or 220 E.H.P. hours per day, an accumulator efficiency of about 50 per cent. On an average line he would put engine and dynamo efficiency at about 77 per cent., accumulators at 60 per cent., and motor, gear, and starting devices at 60 per cent., a total efficiency of about 28 per cent. He preferred a single motor to two. There was sufficient adhesion on ordinary roads if the gradients were under 5 per cent. The combined efficiency with a two-motor car was about 5 per cent. less than with a single-motor one ; where there was a field for the double motor was for a line serving between a residential district and a town, the motors being run in series in the town, and in parallel outside. With regard to gearing, he had no experience of gearless motors, but thought they would be best if the stoppages were not frequent. Double reduction had the advantage that the motor was lighter, as it could run at higher speed.

Mr. BLACKWELL had had considerable experience in America. The great mistake that pioneers there, as here, had made was that they calculated the power required, and calculated it much too low. The practice of one road was no criterion of that on another ; they varied so much both in gradients, local conditions, and regularity of load. Their figures were often not comparable ; the line which on paper appeared to be the most expensive often paying the best. The great difficulty in the last four years in America had been the gearing. All kinds had been tried, but he considered that single reduction held the field to-day. He was formerly much opposed to worm gearing, but was now partly converted, but would like to ask the author for some figures on the cost of working with various forms of gearing. As to cost he knew of no case where horses had been replaced on a line by electric traction in which there had not been a great increase of profit. The number of passengers carried on two of the Boston lines increased respectively 70 per cent. and 30 per cent. With regard to Mr. Manville's remarks about interference with the telephones he quite agreed with them. In America the tramway companies tried to

* Paper read by Mr. A. Reckenzaun before the Institution of Electrical Engineers, March 24, 1892.

Digitized by Google

avoid interference with the telephones by using double wires, but the two-wire system was found to be impossible on any but the smallest lines, and most unsightly.

Mr. CONDICT agreed that there would be a great advantage in the use of accumulators at the station as steadiers. He believed in the author's plan of dividing up the field-magnets into sections for varying the power, and had gone further in America, where they sometimes used a double armature with a commutator at each end, the two being used either in series or parallel. He had obtained very good results with worm gearing, and had made some tests in which it came out very well, compared to both single and double reduction gear. To the latter he was strongly opposed on account of its noisiness. With regard to weight of his cars, he would put car, battery, and motor at 5,000lb. each, and 80 passengers at 12,000lb.

Mr. JARMAN believed strongly in the accumulator system, especially as they could be put on any ordinary line with horse cars without altering the track. The present horse lines might be divided into two classes, those that paid and those that did not. The former did not want to change to power, and the latter could not afford to do so. In his own work they often ran gradients of 1 in 16 with 68 passengers on a 44-passenger car. Accumulators now gave them but little trouble, but he was careful not to take larger currents from them than he could help. He preferred two motors to one, and always used them in series when possible. In reply to a question from the President, he could not give the cost per car mile including cost of renewals, but proposed to read a Paper on the whole subject at a future date. His cells had been running two years without renewals.

Mr. SELLON objected to the author saying that the expenses of the Blackpool line were 67 per cent. of the gross receipts. There was some £373 to be deducted for part of rent paid to the town, and other items, and this brought the figure down to 43·1 per cent. Two of the winter months also they were running at a loss. Taking from April to September only, the cost was £1,524, and the receipts were £5,570, giving 27 per cent. With regard to accumulator traction, he believed one set had run 4,000 miles, with 785 discharges and no renewals.

Mr. CROMPTON said that the reason cells did not last was that the outer surface of the active material was always being jarred off. The right direction to work in was to try and get some non-pasted cell, and also to improve the springs of the cars. In crowded cities he thought the accumulator system was the only feasible one.

Mr. TROTTER said the load diagrams nearly gave as much useful information on mechanical matters as on electrical ones. Much could be learnt from these diagrams as to the effect that a heavy fly-wheel on the engine would have, and to what extent governors would be useful. For integrating the curves to find the total amount of power, he drew them on the oiled paper used in copying letters, and then cut them out and weighed them. The circumscribed rectangle represents a certain number of ampere hours, and the proportion between the weight of the curve and that of the remainder gave the load factor.

Mr. WILLANS said the mean current appeared only to be 30 per cent. of the maximum, which was a very wasteful arrangement. Americans rather objected to using compound engines on the ground that they were not economical at low loads; this, however, was not correct. It was true, however, that a compound had to be larger than a simple engine, as in the former steam would not be admitted during the whole stroke as it could in a single engine on emergency. Mr. Baker had brought a dynamo with him from America with a 10-ton fly-wheel, and he thought a good deal was to be done in storage by that means. He agreed with a previous speaker that it would be well to start the motor free, and bring it into gear by a friction clutch, as it should save a great deal of loss in the leads, and the inertia would help the starting instead of opposing it, as it did when starting from rest.

Mr. SWINBURNE wished to know why such large H.P. was required; 30 H.P. of motors on a car usually drawn by two horses. Mr. Field had told him he was running a car with a 2-H.P. motor, coupled direct through rods, thus avoiding gearing loss.

Mr. FRAZER said there was no need to use much power to start a car, if you only did it slowly enough. The starting current at Barking, with all resistance in, was 40 A., and the running current about 30 A., the maximum being 70 A., for 200yds. on a 3 per cent. gradient. The voltage was 100. Time required to get up speed (eight miles an hour), half a minute.

Mr. RECKENZAUN, in reply, said, with regard to the Southwark railway, it was running under different conditions to a tram line; being worked by signals, it could be arranged that more than two trains need not start at once. He thought that if Mr. Baker had added a competent English engineer to his staff of American ones he would have saved much of his preliminary expense. He spoke of the engine at Roundhay working much under power, its average output was certainly only 75 H.P., but a maximum of 165 H.P. being sometimes required the engine could not well have been much smaller. With regard to starting the motor light and then throwing it into gear he had tried this nine years ago, and found it quite useless; even when there was a 120lb. fly-wheel on the motor it was pulled up before the car started. The 17-ton car mentioned by Mr. Russell he thought a very excessive weight. The ordinary American cars, with passengers, weighed about nine tons. Two motors he considered much better than one, and American practice confirmed this view; mechanical coupling of the two sets of wheels he thought bad, as it produced so much friction. He quite agreed with Mr. Crompton's remarks on batteries. He could not quite understand the line which Mr. Swinburne spoke of as being said to run with 2 H.P.; he himself had begun with one 4 H.P. motor, but it would not do. The Americans now use two 15 H.P. motors. If one breaks down the other will run the car, and the two together are wanted when a car leaves the rails. The pull required to start a car he had found from several tests was from 100lb. to 200lb. per ton

LEGAL INTELLIGENCE.

Wilson and Wife v. National Telephone Company.

In the Queen's Bench Division, on Tuesday, before Mr. Justice Laurence, the above action was heard.

The plaintiffs, Mr. Albert Wilson and his wife, claimed to recover damages for personal injuries sustained by the latter through the negligence of the defendants' servants. The Company did not dispute their liability, and paid £75 into court, contending that that was sufficient to meet the plaintiffs' claim. While some of defendants' workmen were engaged in securing a pole at the top of a house and placing some wires along the coping, some bricks were displaced and fell down, Mrs. Wilson being struck in the back and knocked down. The defence was that the claim was a greatly exaggerated one.

Mr. Morton Daniell appeared for the plaintiff; and Mr. Cock, Q.C., and Mr. Bremner for the defendants.

The learned Judge came to the conclusion that the amount paid into court was sufficient to meet plaintiffs' claim, and gave judgment for the defendants with costs.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April* 2, 1892.

The Progress of the Overhead Trolley System.—The use of the overhead trolley system of electric street car propulsion is gradually making its way into the large cities of this country. As is well known, Boston was the leader in this regard, having now in operation between 200 and 300 miles of overhead trolley line. St. Paul and Minneapolis have for some time had systems aggregating not far from the same number of miles; while Cleveland, Buffalo and Rochester, as well as St. Louis and Cincinnati, have systems that have demonstrated the practicability of the trolley for large cities. Brooklyn recently fell in line by granting to all the roads of that city permission to adopt this system on their lines; and Philadelphia has now placed itself on record as favouring the same method of street car operation for its business and other thoroughfares. Last week the aldermen of that city granted permission to every street car line in the city to use the overhead system; and notwithstanding the mayor's veto in view of the citizens' protest against the granting of the franchise without a payment of a certain part of the earnings in return for this valuable franchise, the aldermen have just passed the ordinance over the mayor's veto; and so one more of the metropolitan cities of the country will at once proceed to substitute the electric motor for its horse methods of operation.

The Marcel Deprez Transmission of Power Patent.—Considerable comment has been caused during the past ten days by the issue of a patent to Marcel Deprez and Jules Carpentier by the United States Patent Office, which seems to cover broadly the transmission of power by means of step-up and step-down transformers. This patent, as many of your readers will remember, was granted to the same parties in England and France in 1881. It was not, however, applied for in this country until 1888. It is stated by those who are in a position to be thoroughly acquainted with the facts that the patent cannot be held to be valid for two reasons; first, that it was applied for after two years of public use, and, second, their patent as issued does not cover the same ground as the English and French patents mentioned above, but that it was juggled into the shape in which it was issued through the ingenuity of the patent attorney who had the matter in hand.

The Comparative Efficiency of One or Two Motors for Cars.—The Chicago Electric Club has been discussing a question which has been of interest to electrical engineers ever since the first electric traction systems came into use in this country, namely, the comparative efficiency of one and two motor car equipments. The question has always been a burning one, and does not yet seem to be any nearer settlement than it was years ago. A one-motor car equipment, of course, is generally understood by engineers to mean a single motor connected to both car axles.

CORRESPONDENCE.

COMPOUND WINDING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I beg to offer a correction of a slip made in your able leading article of last week. The first constant-potential machines made in England were those turned out by Messrs. R. E. Crompton and Co. in the end of 1882, but I had nothing to do with them. They were made under the direction of Mr. Gisbert Kapp.

My connection with the subject was earlier. In February, 1882, I converted a Siemens shunt dynamo into a constant potential machine. This was in Paris. In the spring of the same year I ordered three constant-potential machines from the Brush works at Cleveland. Mr. Brush has stated that he knew all along that his series-shunt machines would give constant potential. I still hold that he did not know it till I ordered these three machines.

The constant-potential winding was first published by Edison's American patent. Hopkinson also mentions compounding up in his three-wire patent of July, 1882. I think Mr. F. C. Phillips also took out a patent about the same time. Messrs. Crompton and Kapp's specification was filed after the invention had been published elsewhere; all the same, the credit is due to them of making the first constant-potential machines in this country, and fully realising the importance of the invention.

Of course Mr. Varley was the first to use double winding, namely, in 1876, but he did not use it for constant potential.—Yours, &c., JAMES SWINBURNE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Allow me to correct a slight error in your leader in last Friday's paper. You say that "everybody knew that the first real compound-wound dynamo was built by Mr. Crompton, to the designs, we believe, or under the superintendence of Mr. Swinburne."

The first four compound-wound dynamos were made for Berechurch Hall, near Colchester, in the autumn of the year 1882, and the patents were taken out by Mr. Kapp and Mr. Crompton conjointly. One of these machines was running about the middle of October, and all were down and running by November 10th of that year, and were inspected by Mr. Heaphy on that date. To the best of my belief Mr. Swinburne had nothing to do with Messrs. R. E. Crompton and Co. until he was engaged to fill Mr. Kapp's place in December, 1885.

I may mention that I had the running of those very machines, after they were put down at Berechurch Hall, for about three weeks, after which I returned to the works at Chelmsford. Trusting this may be of sufficient interest to be inserted in your paper, I am, yours, &c., SYDNEY STOKES.

6, Osborne-terrace, Westcombe Park, Blackheath, S.E.
April 12, 1892.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to a statement which occurred in your leader of last week, that you believed Mr. Swinburne to have designed and superintended construction of the first compound-wound machine for constant potential, allow me to say that you are undoubtedly in error. In part of 1882 I was in charge of the test-room at Chelmsford, and was associated with Mr. Gisbert Kapp in carrying out experiments with shunt-wound machines with Bürgin armatures. It was during the course of those experiments that Mr. Kapp hit on the idea of combining the shunt and series winding, and within a very short period we had tried and ascertained the value of the combination. I believe a patent was applied for in Messrs. Kapp and Crompton's joint names, or *vice versâ*.

I think the first compound machines put into practical use were those put down at Berechurch Hall, near Colchester, the residence of Mr. Coope, M.P.—Yours, &c., W. B. SAYERS.

Glenwood, Bearsden, near Glasgow.

[It would be worth while making a slip now and then, if so much interesting historical information could be always elicited. Mr. Swinburne's claim that he was the first to "compound" a dynamo has never yet been disputed. It was the recollection of this that led to the mistake.—Ed. *E.*]

GASSNER'S DRY CELLS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Those of your readers who are telegraph engineers or those in any way interested in batteries, and having no experience of *dry* cells, no doubt would like to know something of their practical value; so I will ask you to permit me to trespass a little upon your space, and furnish a few particulars of the Gassner Dry Battery, which I have given my attention to lately.

The full details of the construction are known only to the inventor and the makers; but I think the following will serve to give a general idea:—

The negative element is carbon specially manufactured, distinguished by its remarkable porosity, and contains a most efficacious depolarising chemical. Its form is that of a hollow cylinder; the upper parts are well insulated, so as to prevent corrosion at the terminals.

The positive element is zinc, and forms the outside of the cell, and is of sufficient thickness to resist all chemical reactions inside, as far as the exterior is concerned, so that holes will not be eaten through it.

The electrolytic mass inside the cell consists of exciting salts solidified by means of gypsum and water. There is no liquid to drain out, and the great advantage of this mass claimed by the inventor is that its peculiarity prevents the formation of any incrustrations on either element, in consequence of which there is little or no local action.

Last November the manufacturer supplied me with four of these cells, and sent them done up in a bundle by *parcels post* from Milan to Malta. They were by request taken out of a large number without any special selection, so as to represent a true average, but of course with all latest improvements.

My first tests gave the E.M.F. of the battery of four cells as 6·048 volts, or 1·512 volts per cell at a temperature of 71°F. I found the variation to be about 0·3 per cent. per degree Fahrenheit. The internal resistance was as near as possible 0·25 ohm per cell.

Since their receipt I have worked them in various ways; on testing, speaking, and bell circuits; also used them in boats repairing cables, and all kinds of ship and shore work.

The following are the results of tests I obtained of these cells when subjecting them to a severe trial of their sustaining qualities.

1. Two of the cells, Nos. 3 and 4, were placed in circuit of 61 ohms, containing a tangent galvanometer.

Current strength on the first application = 42 milliamperes.
" " after 20 hours' " = 37 "
or a fall of only 5 milliamperes in twenty hours.

2. The same two cells were then practically placed on *short circuit*, the tangent galvanometer having a shunt of four feet of cable core, or only 0·006 ohm, the fall in the current strength being as follows:—

Time.		Deflection.		Current.
Min.	Sec.	Deg.	Min.	Amperes.
0	15	45	0	4·500
0	30	43	0	4·196
0	45	40	30	3·843
1	0	38	30	3·579
2	0	35	0	3·151
3	0	33	0	2·922
4	0	31	30	2·758
5	0	30	15	2·624
6	0	29	20	2·529
10	0	25	0	2·098
15	0	23	20	1·941
20	0	19	0	1·549
25	0	10deg. to 15deg. fluctuating.		—

3. E.M.F. of the cells after the above test,

No. 3 = 0·971 volts.
No. 4 = 0·890 "

representing a mean loss of 31·4 per cent., corrected for co-efficient of temperature variation.

Digitized by Google

4. Nos. 1 and 2 cells were used for several hours in calibrating galvanometers and other work, their E.M.F. falling from 1·482 volts to 1·239 volts.

5. All four cells were allowed to rest for 24 hours.

Cell.	Normal value at 60°F.	Value after above tests	Value after 24 hours' rest.
No. 1	1·482 volts.	1·239 volts.	1·325 volts.
No. 2	,,	1·239 ,,	1·352 ,,
No. 3	,,	0·971 ,,	1·278 ,,
No. 4	,,	0·890 ,,	1·258 ,,

From my experience of this neat and handy form of cell, I can strongly recommend them for general use, more especially on board ship, where portability is a very great consideration. I understand they are employed in the Post Office and by several Continental telephone companies with much satisfaction.

In the hands of novices, for houses, offices, workshops, or steamships, these cells I should say would be found most suitable; and the increase in monetary value over the Leclanché or any other form of battery is more than compensated for by the cleanliness, no attention wanted, and the fact that they can be stowed anywhere, and in any position, giving out no smell whatever, and without fear of getting broken.

As to the life period of these cells of course I cannot give any idea. The following are the present values of the above-mentioned cells after four months' work on various circuits, including short-circuit and considerable knocking about:—

No. 1 = 1·228 volts
No. 2 = 1·355 ,,
No. 3 = 1·358 ,,
No. 4 = 1·179 ,,
} @ 74° F.

or a mean loss of 12·6 per cent. The manufacturers state that a battery of these cells has been working over two years and still remains in good order: but this has to be verified by the experience of others. Perhaps some of your numerous readers can enlighten us on this point.

It is worthy of note that these cells can be regenerated by charging them in the same way as accumulators, without the electrolytic mass becoming liquefied, recovering their loss, and attaining almost normal values.

I shall continue to watch the changes in these cells, and wait with much interest their ultimate decline, which is now the only question of their practical success and superiority in many ways over the existing forms of batteries.—Yours, &c.,

Gibraltar, March 20, 1892. W. H. Cottrell.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892.

The tenth annual edition of the above well-known annual is now ready, price 7s. 6d.; post free, in the United Kingdom, 8s. 3d.; abroad (with the exception of a few countries), post free, 8s. 10d.

The edition consists of between 900 and 1,000 pages, and special care has been taken to make the Directorial division of the book, which has been considerably extended, thoroughly accurate and reliable. In this respect no possible comparison can be made with any similar publication.

To the Handbook division has been added several features which will be found of service to the Electrical and Allied Trades. The Digest of the Law of Electric Lighting has been thoroughly revised and brought up to date, and the most recent Board of Trade Regulations are also included. The various tables and tabulated statements have been remodelled and amplified; and a new feature is the tabulation of valuable information respecting Electrical Limited Liability Concerns.

An important feature is the space devoted to the officials of Foreign and Colonial Governments who have the superintendence of contracts and the giving of orders for electrical plant and apparatus; and as this has been kindly supplied by the various Government departments, it can be relied upon, as can also the particulars given respecting the Home Government departments.

The profession will find "The Electrician" Electrical Trades' Directory and Handbook a trustworthy work of reference, and purchasers of plant and apparatus may confidently turn to its pages for the names of all the principal firms supplying their requirements. Nearly every firm of any standing in the Electrical and Allied Trades is represented in its advertisement pages.

A digest of the contents of the book will be sent on application.

Tenders Invited.—Mr. Robert Mitchell is prepared to receive tenders for a complete installation of telephones and electric bells to be erected at the new Hotel Metropole, Sackville-street, Dublin. Plans and specifications may be had from Mr. Walter Leake, of 30, Victoria-buildings, Manchester, on receipt of an entrance fee of £1. 1s., which will be returned on receipt of a bonâ fide tender. Tenders must be sent in to Mr. Walter Leake not later than April 27th. Further particulars are given in our advertisement pages.

——— The Directors of the Woolwich District Electric Light Company (Limited) invite tenders for the supply and erection of the necessary machinery, &c., for a 1,000 light central station, including underground mains. Further particulars, including plan of the district to be lighted, may be obtained after the 19th inst. at the offices of Mr. J. A. Findlay, secretary, 11, St. Helen's-place, E.C., on payment of £1. 1s. Tenders have to be in by 11 a.m. Monday, May 2nd. Further particulars are given in our advertisement columns.

——— The Bradford Corporation invite tenders for the work in connection with the extension of the electricity station in Bolton-road, Bradford. The work includes new roofing, iron work, and brick and concrete flooring. Tenders have to be in by April 26th. Specifications and plans can be seen at Mr. Shoolbred's offices, at 13, Victoria-street, Westminster, or at the offices of Mr. McGowen at the Town Hall, Bradford.

——— The Corporation of Huddersfield invite tenders for the electric wiring and electric light fittings for the Town Hall and Borough offices. Tenders (addressed to Mr. A. B. Mountain, Borough Electrical Engineer, 1, Peel-street, Huddersfield,) must be in by 10 a.m., on Thursday, the 28th instant.

Belgrade.—The contract for the plant for the electric lighting at Belgrade has been secured by the Continental Edison Company of Paris. Six 60-unit Edison machines are required for the incandescent lamps, and three Sperry-Edison dynamos will supply 40 arcs each. The dynamos will be driven by three Weyher Richemond engines of a new type. The boilers are to be by Babcock and Wilcox, Limited.

Dissolutions of Partnership.—The partnership between M. Mercier and G. S. Corlett, trading as Mercier, Corlett and Co., electrical and mining engineers, &c., at Wigan and Bolton, has been dissolved.

——— The partnership between H. E. Childs and F. C. Berry, of 22, Denmark-street, Soho, London, electrical engineers (trading as Thurkle and Co.), has been dissolved.

Fire at Messrs. Davis and Timmins (Limited).—We regret to announce that on Sunday morning last the premises of Messrs. Davis and Timmins (Limited), of 24, Charles-street, Hatton-garden, E.C., were destroyed by fire. The fire broke out in the adjoining premises, and in a short time the whole of the valuable plant and machinery and extensive stock were destroyed. We are pleased to learn that the firm were fully insured. It will, however, take some time before they can replace their loss, as a large proportion of the tools and special labour-saving machinery used will have to be specially constructed. In a circular issued by the firm, they notify that they have arranged for the present to carry on the whole of their business at their York-road, King's Cross, Works, pending the rebuilding of the Charles-street premises. Although most of the books have been saved, Messrs. Davis and Timmins will be obliged if customers will furnish them with copies of any orders unexecuted, and fresh samples.

General Electric Company.—The third edition of the illustrated catalogue of telephones and telephone accessories has been issued by this Company. A large number of instruments are illustrated, receivers and transmitters being mounted in a great variety of patterns. Insulators, batteries, wire, and tools are to be found in this catalogue, which includes estimates for the erection and fitting of installations.

Electric Mining Plants.—Messrs. John Davis and Son, of Derby, notify us that they have completed, or have in progress, five or six plants of considerable size, for lighting or combined lighting and power purposes. At the Swanwick Collieries, near Alfreton, Derbyshire, a small plant was erected two years ago for lighting the surface at one of the pits; and this has been extended to the underground roads, and to another pit 500yds. distant, and also drives a pump at a distance of about a mile from the dynamo. The plant is subsequently to be enlarged by the addition of a second dynamo, and of a continuous-current transformer, which will charge a battery at Alfreton Hall, the residence of Mr. C. R. Palmer-Morewood, about two miles distant. At the Sheffield

Digitized by Google

Coal Company's Birley Colliery, a large lighting plant is in course of erection, and a similar one has been lately finished at the Bolsover Colliery, on the Duke of Portland's estate. The latter plant lights the whole colliery and brickworks, and also the manager's house. At the New Morgan Gold Mining Company's mine, near Dolgelly, North Wales, a lighting plant, with two dynamos driven from a turbine, has been erected, to light the stamp mill, compressor house, mine, &c. The dynamos are placed in a portion of the stamp mill; and the mains to the mine, which is about one mile away at the head of the ravine, are of bare copper, carried on poles. In this case, as the water-power is rent free, electricity is greatly superior in economy over oil, which is the only other available means of lighting. Messrs. Davis have also in hand a very large and complete colliery lighting plant.

W. T. Henley's Electric Light and Power Company (Ltd).—By a resolution passed March 21st, and confirmed April 7th, this Company is to be wound up. Mr. J. H. Stephens, C.A., of 6, Clement's-lane, E.C., is the liquidator.

Muir, Mavor, and Coulson (Limited).—By a resolution confirmed March 31st, this Company has been wound up, Mr. T. A. Craig, C.A., acting as liquidator. Claims should be sent to liquidator at 139, St. Vincent-street, Glasgow, by April 18th inst.

Carbrook Forge and Steel Company (Sheffield).—Mr. J. W. Randall, of 110, Cannon-street, E.C., has been appointed London representative of this firm.

"Adressbuch der Elektrotechnik und verwandter Zweige, 1892."—We have received from Herr A. Balck the first issue of his Directory of the electrical and kindred trades in Germany, Austria, and Switzerland. Alphabetical lists of firms in these three countries are followed by a comprehensive classified trades' list, and this again by lists of the principal central electric lighting stations and of the electric railways and tramways in operation in the countries named. An appendix enumerates the various principal technical universities and schools, technical institutions and societies, &c. The Directory makes a creditable commencement, and promises to become a useful annual.

The "Local Government Journal."—The proprietors of the old-established *Metropolitan* have altered the title of their publication to the *Local Government Journal*, by which name it will in future be known. The *Metropolitan* was established in 1872, and is recognised as the leading journal for all kinds of contracts and tenders, and Local Government notices.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by Mr. J. C. Chapman, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS

Note.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

March 17, 1892.

5,245. J. Pedder. Appleton-in-Widnes. Improvements in the production of caustic soda and carbonate of soda by electrolysis, and in apparatus therefor.

5,256. G. Percival. Cork. Improvements in the mechanical construction of dynamo armatures.

5,311. J. C. Richardson. London. Improvements relating to the construction of electrodes for electrolytic purposes.

March 18, 1892.

5,365. Munro's Electrical Manufacturing Co. (Limited), and J. MacFarlane. Glasgow. Improvements in joints for electric light fittings.

5,380. G. W. Ready and J. Palfreeman. London. An improvement in pendant electroliers for electric lighting.

5,383. J. A. Kingdon. London. Improvements in the means of synchronising alternating-current dynamos and of working them in parallel and taking them out of parallel.

5,404. J. H. Steward. London. Improvements in magnetic compasses.

5,409. G. E. B. Pritchett and T. W. Pritchett. London. Improvements in secondary batteries.

March 19, 1892.

5,432. E. D. Taylor. London. An improved automatic electric security lock.

5,442. F. F. Bennett and F. A. Colley. Sheffield. Improvements in galvanic batteries.

5,474. A. Hirsch. London. An improved incandescent arc lamp.

March 21, 1892.

5,498. C. A. Stevenson. Edinburgh. Electrical pilot.

5,511. W. S. Hedley. Brighton. Means for arranging automatic shunt circuits, for electrical purposes.

5,515. J. Jergle. London. Improved regulating device for the carbons of electric arc lamps.

5,526. Siemens Bros. and Co. (Limited), and F. G. Baily. London. Electric apparatus for producing flashes.

5,528. H. S. J. Booth. London. Improvements in coin-freed telephone apparatus. (C. Hermann, France).

5,546. J. W. Swan. London. Improvements in or connected with the electrolytic deposition of copper or other metals.

March 22, 1892.

5,579. J. Swinburne. Teddington. Improvements in dynamo-electric machines and motors, in direct current distribution, in leading in wires for incandescent electric lamps, and in the insulation of electric transformers.

5,618. T. Boyden. London. Improvements in alternate-current transformers.

5,634. J. Y. Johnson. London. Improvements in electrically controlled elevators and switch mechanism for use therewith. (N. Hiss, United States).

5,645. L. Pyke and E. S. Harris. London. Improvements in or connected with electric batteries.

5,652. H. H. Lake. London. Improvements in and relating to conduits for electric railway conductors. (The Thomson-Houston International Electric Company, United States).

5,654. A. C. Reignier. London. Improvements in dynamo-electric machines.

5,655. J. P. Rees. London. An improved electric safety lamp.

March 23, 1892.

5,712. G. L. Anders and W. Köttgen. London. Improvements in and connected with diaphragms of telephones.

5,732. J. A. Lea, J. F. Lea and A. H. Lea. London. Improvements in or connected with electric light fittings.

5,735. H. Hirst. London. Improvements in connections for electric lighting.

5,748. G. Shann. London. Improvements in electric meters.

5,750. E. H. Johnson. London. Switch for electrical circuits. (Date applied for under Patents Act, 1883, Sec., 103, August 25, 1891, being date of application in United States).

March 24, 1892.

5,812. H. R. Low. London. Improvements in arc electric lamps.

5,814. Sir C. S. Forbes, Bart. London. Improvements in microphones and in apparatus connected therewith.

March 25, 1892.

5,828. C. H. Falkenstein and K. K. Falkenstein. London. An improved method of rapid tanning with the aid of electricity.

5,850. R. J. Urquhart. Manchester. Improvements in or connected with telephone fittings.

5,870. A. O. Arnesen and E. Wölner. Liverpool. Magnetic course indicator.

5,891. W. T. Mathews. London. Improvements in or connected with holders or supports for the ear tubes of telephones.

5,899. E. F. M. Loevenbruck. London. Improvements in apparatus for adjusting and regulating the carbons of electric arc lamps.

March 26, 1892.

5,931. W. L. Spence. Manchester. Improvements in the construction of multipolar dynamo-electric machines.

5,933. G. Sacco. London. New accumulator battery for telegraph offices for military telegraphs in the field, also for lighting trams, omnibuses, carriages.

5,954. F. Brown. London. Improvements relating to voltmeters.

5,959. J. Spisd and H. Nowak. London. Improvements in accumulators.

March 28, 1892.

5,971. S. W. Baynes. Bradford. Improvements in underground conductors for the distribution of electricity.

5,982. A. H. Sanderson. Bournemouth. Improvements in joints and connections for electrical purposes.

5,988. J. S. Raworth and W. Geipel. London. Improvements in or relating to the distribution of electricity.

6,006. T. Parker and A. E. Robinson. London. Improvements in the treatment of electro deposits of metals.

6,007. T. Parker and A. E. Robinson. London. Improvements in or connected with cells for electrolysing chloride solutions.

6,015. R. R. Harper. London. Improvements connected with shades and shade or reflector holders for incandescent electric lamps.

March 29, 1892.

6,030. W. P. Thompson. Liverpool. Improvements in insulated electric conductors. (J. B. Williams, United States).

6,058. W. F. Taylor. Croydon. Improvements in machinery for the purpose of hardening and tempering metals by electricity.

6,061. A. Whalley. Cheshire. Improvements in telephone switchboards.

6,083. F. S. Smith. London. Improvements in incandescent electric lamps.

6,033. M. Boehm. London. Improvements in the manufacture of filaments for incandescent electric lamps.

6,095. R. Belfield. Strawberry Hill. Improvements in conductors for electric railways or tramways.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1891.

3,984. PATIN. Electric arc lamps.
4,669. HIRBEC. Generating electricity.
4,682. DE FERRANTI. Electrical supply systems.
4,684. MAYES. Measuring and adjusting magnetic force.
6,048. NORTH. Electric power apparatus.
6,489. PRYKE. Electric incandescent lamps.
6,793. CHAMPION. Producing pyrotechnic, &c., effects by electricity.
7,850. HORN. (Strowger). Telephone exchanges.
7.858. SNELL AND OTHERS. Electrical switches.
7,878. ROWAN AND MCWHIRTER. Preventing ignition of gases in dynamos, &c.
7,911. GRIMSTON. Electric switch.
7.912. GRIMSTON. Electric capstan.
7,937. COX. Electric resistance devices.
8,153. SIEMENS BROS. AND CO. (LIMITED). (Siemens and Halske). Electrically propelled cars.
12,107. DOW. Electric light, &c., fittings.
19,965. LOVE. Electric conductors.
21.551. PITT. (Sautter, Harlé and Co.) Electric light projection.
22,037. LAKE. (Wright). Printing telegraph receiving instruments.

1892.

1,313. SHORT. Electric motor cars.
1,557. THRELFALL. Electro-magnetic apparatus.
2,448. WENTZ. Telegraphic relays.
2,497. HUNT. Magneto-electric machines.
2,724. GRIMM. Electro-therapeutical apparatus.
2,744. HOFFMANN. Telephonic instruments.

COMPANIES' MEETINGS & REPORTS.

New Australian Electric Company.

The third annual meeting of shareholders in this Company was held recently at Fink's-buildings, Melbourne. Mr. B. J. Fink presided.

The SECRETARY (Mr. H. Ashworth) read the notice convening the meeting, and the report of the Directors. The balance-sheet and statement of accounts for the twelve months ended December 31, 1891, showed a net profit for the year of £6,474. 1s. 10d., which, added to the amount brought from last year, gave a balance of £11,190. 6s. 6d. to the credit of profit and loss. The Directors state that the plant at the Richmond lighting station is in first-class order, and its working fully realised the anticipations of the Directors with respect to its efficiency and economy. The amount of business done by the Company during the last twelve months had been most satisfactory. Lighting had been extended in many directions, and numerous orders for installations and plant had been executed. In 1889 an equivalent of 6,954 incandescent lamps was supplied; in 1890 the number was 9,086, and in 1891 14,566; and at the present time the supply was increasing at the same ratio. During the year Mr. W. Brookes had resigned his position as a Director, and Mr. Wilfrid N. Kernot had joined the Board. Prof. W. C. Kernot (the Chairman) was at present on a visit to Europe and America, and was obtaining information on electrical matters which would be of service to the Company.

The CHAIRMAN, in moving the adoption of the report and balance-sheet, said the works of the Company were quite equal to any works of the kind in the old world. There had been uninterrupted smooth working during the past few months, and several thousands of pounds had been spent on the extension of the buildings, which would now admit four more engines, or rather more than double the previous capacity. They had not been able to erect additional plant because additional capital would be needed to do that, and the unfortunate financial times stood in the way of successfully placing more shares on the market. The plant was fully employed, and the income was now a very large one. The rumours as to the dangers of electric lighting had been pretty well dissipated, as there had been no accident of any kind during the past 12 months. The Directors had to congratulate the shareholders on the very satisfactory, he might almost say brilliant, results of the last year's operations. A handsome dividend could have been declared, but every pound was needed for the business, as would be admitted by every shareholder who might choose to go and see the magnificent station and plant at Richmond.

The motion was seconded by Captain ROWAN, and carried unanimously.

Prof. Kernot, Mr. B. J. Fink, and Mr. J. F. Levien, M.L.A., were re-elected Directors.

Maxim-Weston Electric Company (Limited) (in Liquidation).

A general meeting of the members of this Company was held at the Cannon-street Hotel on Friday last, under the presidency of Mr. John Marks, one of the liquidators.

The CHAIRMAN explained that at the time the liquidators were appointed there was heavy litigation pending with regard to a large proportion of the Company's affairs. The claims by and against the Company had, with the approval of the Directors of the new Company, been settled, with the exception of the Watt litigation, and the claims by and against Palmer's Ship Building Company and the Brighton Corporation. The liquidators recovered against Mr. Watt £1,000 with costs in both the actions raised by him. Although they gained the case against the Brighton Corporation, the arbitrator awarded the Corporation damages exceeding by about £7 what was recovered by the liquidators. The official referee had ordered a return of the plant to the Company, and awarded Palmer's Company damages for an inefficient installation, and the costs. Having explained the various items in the report and account submitted, he concluded by moving their adoption.

Sir HENRY HOARE seconded the motion, which was carried.

Resolutions were afterwards passed, disposing of the books, accounts, and documents of the Company, and of the liquidators; and voting, in various proportions, the remuneration of the latter.

At a meeting of the new Company, held subsequently, similar resolutions were adopted.

Indo-European Telegraph Company (Limited).

The following is the Directors' report for 1891, which will be presented to the twenty-fifth ordinary general meeting, to be held at Winchester House, E.C., on Wednesday, the 27th inst., at noon.

The Company's revenue from all sources for 1891 amounted to £116,699. 3s. 1d., as compared with £113,807. 3s. 11d. for 1890, showing an increase of £2,891. 19s. 2d. The expenses were:—On commercial and general account, £30,581. 5s. 3d.; on maintenance account, £30,527. 7s. 7d.: total, £61,108. 12s. 10d., as against £57,901. 19s. 7d. for 1890, an increase of £3,206. 13s. 3d. Deducting the above expenses, taking credit for £4,168. 16s. 7d. brought over from 1890, and debiting income-tax, there remains the sum of £58,483. 15s. 4d.

From this amount £10,000 has been placed to reserve, and that sum, together with £10,625 amount of interim dividend, have to be deducted, leaving a balance of £37,858. 15s. 4d. The Directors now propose the declaration of a dividend for the six months ending December 31st of 17s. 6d. per share, making, with the dividend already paid, 6 per cent. for the year and a bonus of 20s. per share, both free of income-tax, making in all 10 per cent., carrying forward £5,983. 15s. 4d. to the credit of 1892.

The new rules, regulations, and tariffs of the International Telegraph Convention settled at Paris, have had full effect since July 1st last; but, as anticipated, have had no material influence upon the Company's revenue.

The arrangement with certain of the Australian Colonies for the introduction of a greatly reduced tariff between Europe and Australia came into force on May 1st last. It will be remembered that Queensland and New Zealand decided to remain outside the above arrangement. The outcome of the reduced rate, so far, has been an increased traffic, coupled with a diminished receipt. On the whole, however, the results have been sufficiently promising to induce the Governments and Companies concerned to continue the experiment for at least another twelve months.

The following Directors retire by rotation, and offer themselves for re-election:—H. Weaver, Esq., and L. Delbrück, Esq. The auditors, Messrs. C. F. Kemp, Ford, and Co., public accountants, retire and offer themselves for re-election.

Oriental Telephone Company (Limited).

The following report of the Directors of this Company for the year ended December 31st last, has been issued, and will be presented at the twelfth ordinary general meeting of the Company, to be held at the Cannon-street Hotel, on Wednesday, the 27th inst., at one o'clock.

The revenue account for the year ended December 31, 1891, shows a balance to credit of £8,918. 13s. 10d., which has been transferred to profit and loss, and including £2,250. 19s. 9d. brought forward from the previous year, a balance remains for disposal of £11,169. 13s. 7d. The Directors propose to deal with this as follows:—To write off £257. 0s. 4d., legal and other expenses caused by the action brought by holders of vendors' shares; £1,466. 4s. 8d., in reduction of capital expenditure; to add £3,000 to reserve fund, which will then stand at £10,000; and to pay a dividend of 2¼ per cent., free of income tax, on the total paid-up capital of the Company, carrying forward £1,857. 16s. 4d.

As the shareholders are aware, a large portion of the earnings of the Company are in silver currency; and, owing to the low exchanges which have lately been ruling, the profit of the year has been somewhat diminished.

As mentioned in the report of last annual general meeting, a copy of which was sent to each shareholder, proceedings were taken by a holder of vendors' shares to restrain the Directors from distributing the profits of the Company in the manner indicated in the last annual report and accounts. The Court having upheld the action of the Directors, the distribution for the past year will be made in the same manner, the 2¼ per cent. on the entire paid-up capital of the Company being equivalent to £3. 12s. 2d. per cent. on each ordinary share of 11s. paid, issued prior to February 4, 1886.

The Indian Companies continue to improve. The Bengal Company has been able to increase its dividend by ½ per cent, the distribution for 1891 being 5½ per cent., whilst the Bombay Company has declared a dividend equal to that of the preceding year, viz., 4 per cent., transferring 10,000 rupees to its reserve and depreciation fund. The Bengal Company already possesses a reserve fund in cash of 50,000 rupees.

The Telephone Company of Egypt, after payment of debenture interest, has declared its usual dividend of 6 per cent. on the preferred shares, carrying forward £1,414. 17s.

The China and Japan Telephone Company's accounts for 1890 closed with a surplus of £841. 12s. 5d, as against £573. 16s. 4d. for the previous year. The accounts for the past year are now in course of preparation.

Digitized by Google

The branches worked directly by the Company maintain their revenues, and in one or two instances slightly show improved results.

The shareholders will remember that last year they approved a resolution to alter the Company's Memorandum of Association so as to embrace "any business or manufacture relating to the generation, employment, or utilisation of electricity or magnetism or the apparatus connected therewith." This resolution having been duly confirmed, application was made to the Court for permission to amend the Company's Memorandum accordingly. The application was, after consideration, sanctioned, but the Court suggested that as the power of extension of business was considerable, the name of the Company should be altered, and expressed approval of its being changed to the "ORIENTAL TELEPHONE AND ELECTRIC COMPANY (LIMITED)."

The Directors see no objection to such alteration, and the following resolution will therefore be submitted for the consideration of the meeting:—

"*That the name of the Company be changed to 'The Oriental Telephone and Electric Company (Limited).'*"

Should the above resolution be passed by the requisite majority, it will be submitted for confirmation as a special resolution to an extraordinary general meeting, which will be subsequently convened.

The Directors to retire at the present meeting are Messrs. Henry Grewing and William Addison, both of whom being eligible, offer themselves for re-election. The auditors of the Company, Messrs. Deloitte, Dever, Griffiths and Co., also retire, and offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, pages 302-322, *&c., &c.*]

CORLETT ELECTRICAL ENGINEERING COMPANY (LIMITED).—This Company was registered on April 7, 1892, with a capital of £10,000, in £10 shares, by Charles Doubble, 14, Serjeants' Inn, Temple, E.C. The objects are to acquire the business of an electrical engineer now carried on by George Stephen Corlett, at Wigan and Bolton, in the county of Lancaster and elsewhere, and the whole or any of the real and personal estate belonging to the said G. S. Corlett in connection with the said business; to carry on the business of electric lighting in all its branches, and in particular to construct, lay down, establish, fix and carry out all necessary cables, wires, lines, accumulators, lamps and works; and to carry on the business of manufacturers of, and to buy, sell, hire, let and deal in dynamos, engines, boilers, lamps, wires, cables, insulating materials, telephones, bells and other apparatus required for, or capable of, being used in connection with the generation, distribution, supply, and accumulation of electricity. The subscribers are:—

	Shares.
G. Stephen Corlett, Wigan, electrical engineer	1
T. D. G. Drayton, Newton-le-Willows, Lancs., colliery proprietor	1
C. Gidlow Jackson, Anderton Hall, Lancs., colliery proprietor	1
W. Johnson, Harewood, Roe-lane, Southport, Lancs., mining engineer	1
J. Brown, 23, Oxford-road, Birkdale, Lancs., cotton spinner	1
W. H. Hewlett, Wigan, coal owner	1
T. Radcliffe Ellis, The Hollies, Wigan, solicitor	1

The number of Directors is not to be less than three nor more than seven, the names of the first to be determined by the subscribers; qualification, £300.

HOLLIDAY AND WILLIAMS (LIMITED).—This Company was registered on April 8, 1892, with a capital of £3,000, in £5 shares. The objects are to carry on the business of general stamped brassfounders, ironfounders, electricians, mechanical and electrical engineers, dealers in engines, tools, implements and appliances, smelters, &c.

THOMAS C. STEEDMAN (LIMITED).—This Company was registered on the 8th inst., with a capital of £5,000, in £1 shares, to carry on the business of importers and manufacturers of and dealers in electrical, chemical, photographical, surgical, and scientific apparatus and materials.

MISCELLANEOUS.—JOSEPH TINN (Limited). Capital, £200,000. Objects: To manufacture black and galvanised iron and steel sheets, rollers of bar, sheet, rail, and other iron, engineers, &c., at the Ashton Iron Rolling Mills, Long Ashton, Bristol, &c.—HENRY BESSEMER and Co. (Limited). Capital, £200,000. Objects: To take over the undertaking of Henry Bessemer and Co. (Limited), in liquidation, to carry on the business of engine and boiler makers, engineers, machine makers, &c.—DISTRICT CHEMICAL COMPANY (Limited), Capital, £50,000. Objects: To manufacture and deal in chemicals, and to acquire inventions or improvements for approved processes for the manufacture of chemicals and the products of chemical processes, &c.

ELECTRIC WIRINGS AND FITTINGS COMPANY (LIMITED).—The annual return of the above-named Company, made up to March 14, 1892, was filed on the 22nd following. The Company was registered on September 11, 1889, with a capital of £5,000, in £1 shares. At the time of making-up, 1,382 shares were taken up, on all of which the full amount had been called. The calls paid amount to £1,375 and unpaid to £7. At the date of the last return, 1,500 shares had been issued as fully paid to Latimer Clark, Muirhead and Co. (Limited), of 23, Regency-street, S.W.; but these by an agreement made November 24, 1890, between Messrs. Latimer Clark of the one part, and the Company of the other part, were cancelled.

ELMORE'S FOREIGN AND COLONIAL PATENT COPPER DEPOSITING COMPANY (LIMITED).—The annual return of the above-named Company, made up to February 12, 1891 (being the fourteenth day succeeding the date of the first ordinary general meeting in 1891), was filed on March 16th last. The reason for the delay is given in a letter of March 1, 1892, from the Secretary, stating that as they had filed a return in January, 1891 (which was, however, for 1890), and as they held their ordinary general meeting on January 29, 1891, it was understood that a return would not be required for the short interval between January 12th and the 29th. At the time of making-up, all the shares had been taken up, of which 6,000 founders' shares had been issued as fully paid. Upon the remaining 3,000 founders' and the 15,000 priority shares, the full amounts have been called, and all calls have been paid. £20 has been paid on 20 priority and 20 founders' shares forfeited. The principal shareholders are Sir Thomas H. Farrer, of Dorking (1,000), F. L. Rawson (5 priority and 1,458 founders'), J. Jepson Atkinson (999 priority and 550 founders'), J. T. Cooper (1,000 priority and 550 founders'), Woodhouse and Rawson United, Limited, of 88, Queen Victoria-street (1348 founders'), James Andrew (567 founders') W. C. Cogalet, of Dorking (deceased), (443 priority and 565 founders'), Francis E. and Alex. S. Elmore, of Spring Grove, Leeds (450 founders' each).

FAREHAM ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of the above-named Company, made up to March 24th, was filed on March 29, 1892. An agreement made on January 15, 1891, between the above Company of the one part and the Laing, Wharton, and Down Construction Syndicate (Limited), determined that certain plant and machinery for the lighting of Fareham by electricity should be sold by the Syndicate to the Company; and in full consideration 1,950 fully-paid ordinary shares, numbered 2,139 to 4,088, both inclusive, should be allotted to the Syndicate or its nominees. According to the return just filed, at the time of making-up, 4,158 shares were taken up, and the full amount called, resulting in the payment of £4,154, and leaving £4 in arrears (making no allowance, however, for the shares issued as fully paid, in accordance with the above agreement).

FOREIGN PILSEN ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of the above-named Company, made up to March 15, 1892, was filed on March 17th following. The Company was registered on January 20, 1885, with a capital of £30,000, in £1 shares, to assume the liabilities, take over as a going concern, and to carry on all or any of the business of the Union Electric Light and Power Company (Limited). At the time of making-up 29,800 shares had been taken up, all of which had been issued as fully paid.

ISLE OF WIGHT ELECTRIC LIGHTING COMPANY (LIMITED).—The statutory return of this Company, made up to April 7th, was filed on the following day. The Company was registered on November 12th last, with a capital of £1,000, in £1 shares. By special resolution, passed December 3, 1891, confirmed December 18, 1891, the capital of the Company was divided into 940 ordinary, and 60 founders' shares. At the time of making-up, 7 shares had been taken up, upon which no calls had been paid, the original subscribers being the only shareholders. No agreements of any kind have been filed.

MINERS' LAMP ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of the above-named Company, made up to February 1, 1892, was filed on March 29th. This is really the return for 1891, February 1, 1892, being the fourteenth day succeeding the date of the first ordinary general meeting in 1891, which was held on November 18, 1891; then, by adjournment, on December 16, 1891; and then, by further adjournment, on January 18, 1892. The Company was registered on January 12, 1889, with a capital of £3,000, in £5 shares. At the time of making-up, 301 shares had been taken up, of which 180 had been issued as fully paid. Upon the remainder the full amount had been called, resulting in the payment of £550, and leaving £5 in arrears.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—In our advertisement pages will be found particulars of the sixth drawing of Five per Cent. Debentures (1884 issue), which will be paid off at par on July 30th next, at the Alliance Bank, Bartholomew-lane, London, E.C., and the interest thereon will cease after July 31st. 168 debentures of £100 each have been drawn.

CALLS DUE.—£5 on INDIA RUBBER, GUTTA PERCHA AND TELEGRAPH WORKS COMPANY, LIMITED (*April 14*); £25 (final) on NATIONAL TELEPHONE COMPANY, LIMITED (*April 21*).

CARBON ELECTRIC (LIMITED).—At an extraordinary general meeting of the members of this Company, held at the Company's offices, 33, Old Broad-street, London, E.C., on February 17th last, the following special resolution was passed, and at a subsequent extraordinary general meeting on March 5, was confirmed:—"Resolved, that the Memorandum of Association of this Company, clause 5, be amended by dividing the capital of the Company into 2,100 Preference shares of £5 each and 1,900 Deferred shares of £5 each, in place of the present division of the capital of the Company."

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended April 10th were £742, as against £830 for the corresponding period of last year, being a decrease of £88. The total receipts to date, from January 1st last, amount to £12,083, against £10,914 in the corresponding period of 1891, being an increase of £1,169.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—An interim dividend of 3s. 6d. per share, free of income-tax (which is at the rate of

Digitized by Google

3½ per cent. per annum), for the quarter ending 31st March, has been declared by this Company. The dividend will be payable on and after the 23rd instant.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment by warrants, on May 2nd next, of interest for the half year ending April 30th on their Four per Cent. Mortgage Debenture Stock. The transfer books will be closed from April 27th to May 2nd, both days inclusive.

ELECTRIC AND GENERAL INVESTMENT COMPANY (LTD.).—Mr. Emile Garcke, formerly Managing Director of the Brush Electrical Engineering Company, Limited, has been appointed Managing Director of the Electric and General Investment Company, Limited.

MANITOBA ELECTRIC AND GAS LIGHT COMPANY (LIMITED).—A special meeting of the debenture holders of this Company was held at 31 Lombard-street, on Monday last, to enable one of the trustees for the debenture holders (Mr. Lionel R. C. Boyle) to resign his position.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—The electric current sold by this Company during the quarter ending March 31st last amounted to £10,024, as against £9,652 for the corresponding period of last year.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ending April 8, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,052.

Electric Communication between Lightships and the Shore.—In response to a requisition, signed amongst others by Mr. Henry T. Foster (Sheriff of London), Sir A. K. Rollit, M.P., Mr. James Lowther, M.P., M. E. Sève (Consul General of Belgium), and the mayors of the boroughs on the south coast, a meeting is to be held at the Mansion House, on the 26th inst., under the auspices of the National Sea Fisheries Protection Association, in support of the resolution to be moved in the House of Commons, by Sir Edward Birkbeck, urging the Government to take steps to establish electric communication between lightships, lighthouses, and the shore, for the saving of life and property at sea.

Self-Governing "Pelton" Water Wheel.—The Pelton Water Company, of San Francisco, have recently brought out a governor. The motor, says *Industries*, is provided with a throttle valve and centrifugal governor to regulate the speed under varying loads. The centrifugal governor is mounted on a spindle having two bevelled friction pinions, which make contact alternately with a larger friction disc, thereby moving it either to the right or left according to the speed of rotation. On the spindle carrying the large friction disc is a worm, which gears with a worm-wheel fixed on the same spindle as a small-toothed pinion. The latter, in turn, gears with a large-toothed sector, which is mounted upon a spindle carrying a winged valve, thereby enabling the adjustment of the valve and the regulation of the water.

Magnetite.—According to some investigations of Holz, magnetite can attain a permanent magnetisation 1½ times that attained by steel, even in strong fields. In a recent number of *Wiedemann's Annalen* Anton Abt gives the results of some experiments of his own on two samples of magnetite from the beds of Moravicza (Hungary). One piece was pure, but somewhat porous; the other was dense, fine-grained, and traversed by yellow veins composed of chalcopyrite, which had mostly been transformed into malachite. Two parallelepipeds were cut out and compared magnetically with similar sized pieces of tempered steel, reheated to blue. Holz's results were generally confirmed. The permanent magnetisation of magnetite was found to be greater than that of steel, but the temporary magnetisation and its retentivity in face of a demagnetising force were less.

The Incandescent Lighting of the Chicago Exhibition.—The tenders (nine in number) for furnishing the incandescent lights at the Chicago Exhibition were opened on April 2nd. In all about 85,000 lamps were enumerated. Some of the tenders were for the entire installation. The Thomson-Houston Company's figure was $14.51 per lamp for dynamos and auxiliary apparatus, and from $3 to $4 extra per lamp with inside wiring complete. The Edison Company's figures were respectively $14.16 and $18.49 per lamp. The seven other companies which sent in tenders were the Brush Company, the Fort-Wayne Company, the Electrical Construction Company (Chicago), the Mather Electric Company, the Western Electric Company, the Heisler Electric Company, the South Side Machine and Metal Works (Chicago). No action, says the *Western Electrician* of April 9th, has as yet been taken by the Committee.

An Artificial Aurora.—An experiment showing "molecular bombardment" and the "aurora" may be made, says Mr. T. B. Heimstreet in the *Electrical World*, by rubbing an incandescent lamp on the clothing, or on paper, leather, sheet rubber or tin foil, when the bulb will become filled with light; if you stop it grows dark. If touched with the finger the filament and the interior will be a bright glow lasting from one to three seconds; if touched again it is repeated; by drumming or drawing the finger slowly over the glass the light is quite continuous. If rubbed on newspaper in an absolutely dark room, the larger letters can be read at a distance of two or three inches. Fan the bulb with sheet rubber eight or ten inches away, but do not touch the glass, it will light the same quite bright if the fanning is very rapid. The lamps used were the Edison 16 c.p., 20 and 22 volts. Most of the miniature lamps will give the light, but not all; the 110-volt store lamps will not.

The Chicago Exhibition.—A meeting was held in the Manchester Town Hall on the 8th inst. to hear addresses from Mr. McCormick, the Commissioner from Chicago, Sir Philip Cunliffe Owen, Sir Henry Trueman Wood, and Sir Douglas Galton. Each of these gentlemen explained at length the reasons why they thought that Manchester manufacturers and merchants should exhibit at Chicago; and Mr. McCormick dwelt upon the efforts which were being made by the United States to extend its trade, and to the volume of trade done with England. Mr. Alderman Bailey said he did not know any engineers in this district who proposed to exhibit. He thought that the effect of sending exhibits would only be to have them copied, and he proposed to make a special journey in order to see for himself what was being done. There was a general feeling, says *Industries*, that this was the right view to take, and it is very improbable that any extensive engineering exhibits will go from the Manchester district.

The Exhibition of the Société Française de Physique.—The annual exhibition of the Société Française de Physique was held on the 19th, 20th, and 21st, in the building of the Société d'Encouragement. Among the more noteworthy events, says our Paris correspondent, were a repetition by M. d'Arsonval of the Tesla and of the Elihu Thomson experiments. The experiments were very successful, and many were of a novel character. M. d'Arsonval made a great point of showing the difference in the physiological effects of alternating currents of different kinds. M. P. Janet showed an apparatus for the stroboscopic study of alternating currents. MM. Richard Frères showed an electric kinemograph, and an hydraulic dynamometer, which had been used in determining the variation of tractive effort with the speed of a vessel. The same firm also showed a Deprez d'Arsonval galvanometer which registered photographically. M. Ducret showed some apparatus constructed for the carrying out experiments with polyphase currents, and M. Besson exhibited a small plant arranged to enable accumulators to be charged by means of the Giraud thermo-electric stove.

Electricity in Queensland.—The first town in Queensland to instal the electric light is Thargomindah, about 1,000 miles from Brisbane. The plant is being installed by Messrs. Trackson Brothers of Brisbane, to the order of a Mr. Patterson. The price of kerosene oil at Thargomindah averages about £1 per tin; gas is out of the question, as the cost of coal carriage would be something like £10 per ton. There is a splendid supply of water at Thargomindah, and an abundance of wood. Great efforts are being made in Queensland to push the telpher system, the colony being particularly favourable to it. The country is so immense that it is impossible as yet to lay down a sufficient mileage of even the lightest railways with any hope of their paying. The idea in using the telpher system is that it should serve as a feeder to the few railways that exist. On the sugar plantations the introduction of the telpher system is viewed with considerable favour, as it would be an ideal way of conveying the cane over long distances. Messrs. Trackson Brothers have just received an order from the Government for the supply of all the electric light fittings for the new wing of the Parliament House, the chief condition being that all the fittings shall be manufactured in the colony.

A Simple Method of Obtaining a Rotary Field.—In the *Electrical World* of April 9th Mr. W. S. Horry describes a simple method of obtaining a rotating magnetic field for experimental purposes from the mains of an ordinary alternating current company. He points out that in an ordinary transformer when loaded the primary and secondary currents are almost exactly opposite. When, however, a 20-light transformer has but one light burning on the secondary circuit, the phase difference between the two currents is substantially 90deg. We have then, says Mr. Horry, in this second case a very practical means for producing a phase difference that can be made to cause rotating magnetism in an iron ring. All that is necessary is to wind the ring with two wires so that there are two vertical and two horizontal poles, and to connect one in series with the primary and the other in series with the secondary circuit of an underloaded transformer. The transformer in this condition

Digitized by Google

will give off two currents, which can be of the same strength, and both differing as regards phase. If an iron disc be inserted in the centre of the ring and be left free it will revolve. It is necessary in a motor of this type to have the phases as nearly in quadrature as possible, otherwise we get opposing forces, one tending to pull the armature round and another less powerful force tending to stop it. The efficiency of a motor constructed in this way is unimportant. The desire is simply to call attention to the way in which a very workable current splitter can be made that will produce a rotary magnetic field from simple alternating currents.

The Co-existence of Specific Inductive Capacity and Electrolytic Conductivity.—"The method which I used to measure the dielectric constant of mica at a high temperature," says M. Bouty in the *Comptes Rendus*, Vol. CXIV., No. 10, p. 533, "is applicable without essential modification to dielectrics having a small electrolytic conductivity. The capacity, c, of two rigidly fixed metal plates separated by air is taken, and the plates are then plunged into the dielectric conducting mass. By means of a torsion pendulum the circuit of the condenser is closed on a battery of electro-motive force E and negligible resistance, for a brief known time t, and the quantity of electricity, Q, is then received by a microfarad condenser." According to M. Bouty $Q = E\ (C + a\,t)$, where a and C are constants, $k = \frac{C}{c}$. Applying this method to benzine M. Bouty found $k = 2{\cdot}25$. According to Cohn, Arons, and Tereschin, k for distilled water is forty times greater than the square of the average index; and quite recently Rosa found $k = 75\ 7$. "Unfortunately," observes M. Bouty, "the conductivity of distilled water is far too great, and would necessitate the measurement of times t several hundred times less than the limit of accuracy of my pendulum (0 0001 second)." This objection does not, however, hold good for ice, which at 0° C., has a resistance some 12,000 times higher than water. Distilled water was, therefore, frozen, and a temperature of − 23° C. attained; $k = 78$. The very high specific inductive capacity of ice is therefore beyond question. On allowing the temperature of the ice to rise its conductivity, of course, increased, but its specific inductive capacity remained much the same. It follows from these experiments that dielectric power and electrolytic conductivity are capable of coexisting in the same body, which is conformable to Maxwell's views. Moreover, the specific inductive capacity varies but little under conditions in which the conductivity increases enormously. Water and ice have sensibly the same specific inductive capacity, whilst their conductivity may vary in the ratio of 1 to 10^5 or 10^6.

Statistics of Electric Lighting in Massachusetts.—The seventh annual report of the Board of Gas and Electric Light Commissioners of Massachusetts for the year ended June 30, 1891, has just been issued. The report shows that there were 131 companies under the supervision of the Board, 26 of which supply both gas and electric light; 58 only electric light. The results of the year's operations of the electric light central stations, compared with the year 1890, are as follows:—

	Year ending June 30. 1891.	1890.
Receipts	$2,440,350.65	$1,920,702.05
Expenses	1,735,206.13	1,340,814.60
Balance	$705,144.52	$579,887.45

The amount of net earnings of the electric light departments of gas companies was $110,871.40 in 1890; for 1891, $143,240.78. The net earnings of the electric companies in 1890, $469,016.05; in 1891 they were $561,903.74. In capitalisation the Edison Electric Illuminating Company, of Boston, heads the list with $1,263,500. The total valuation of the electric plants, as shown by the local assessors, was $2,035,160. Dividends were paid by 25 companies, amounting to $262,968. These ranged from a 10 per cent. dividend to one of 1 per cent. The Edison Illuminating Company of Boston paid 5½ per cent. The largest arc light company in the State is the Boston Electric Light Company, with 2,041 arcs. The largest incandescent lighting company is the Boston Edison, which supplies current to the equivalent of 90,000 8-c.p. lights from 64 dynamos. The total number of boilers in use in central stations is 216, engines 261, dynamos 591. Two plants are driven entirely by water-power. Five persons were injured during the year by electricity, one of them fatally. Of the various systems in use in the State the following are noted: Thomson-Houston, Westinghouse, Brush, Schuyler, American, Ball, Waterhouse, Sun, Weston, Electro-Dynamic Company, Arnoux Hochhausen, and Edison Municipal. Of these the Thomson-Houston was used by 69 electric lighting companies, the Westinghouse by 13, the Edison by 10, the Schuyler and American each by 6, the Waterhouse and Brush each by 5, the Ball by 3, the Edison Municipal by 2, and the Electro-Dynamic, Sun, Weston and Arnoux Hochhausen each by 1. The total length in feet of wire in use in the State was 24,632,523; of underground conduit, 219,580; of wire in conduit, 716,187.

Electric Mining in Colorado.—In a Paper recently read before the American Institute of Mining Engineers, Mr. M. B. Holl gives some interesting particulars with regard to the well-known electric plant at Aspen, Colorado. Power for hoisting on some steep inclines is obtained from a 50-H.P. 500-volt constant-potential Edison dynamo, driven by a Pelton wheel 5ft. in diameter, with an effective head of 63ft., placed 6,000ft. from the mouth of the tunnel. The hoisting engine at the inner end is a 7½ H.P. Sprague street-car motor-driving two drums. The working of this motor was so successful that a similar one has been placed at the head of another incline Each of these is designed to raise 250 tons on the incline of 60deg. for a length of 250ft. in 16 working hours during the day. The cost for repairs of the first motor, in addition to the small outlay in replacing commutator brushes from time to time, during three years' constant work, has been as follows:—

	£.	s.	d.
Replacing field magnet-coils	8	19	0
Rewinding one armature	16	13	0
Replacing commutators	15	12	0
Total repairs	£41	4	0

The first of the above items was due to the burning out of the insulation on the magnet-coils, the second from the bursting of the binding-wires on the armature, and the last from the wear between the commutators and the copper brushes originally employed. Recently the latter have been replaced by others of carbon, and since the change the motors have run without shaking, and the wear in the commutators is inappreciable. In the latter part of 1889 the company, which had previously been supplied with power from the Roaring Fork Electric Light and Power Company, erected its own generating plant. This has a capacity of 100 electrical H.P., produced by two 50 H.P. Thomson-Houston motor-type dynamos wound for a constant potential of 500 volts, each of which is driven by two Pelton water-wheels 42in. in diameter paired on the same shaft. A head of 80ft. of water, giving a pressure of about 35lb. per square inch at the foot of the main pipe, is obtained by a lander about 1,600ft. long, having a capacity of 1,000 cubic feet of water per minute. The speed of the wheels can be varied according to the requirements of the power by altering the direction of the impinging jets, for which purpose the delivery nozzles are mounted on a ball-and-socket joint, which is connected by a link-motion with a Woodward governor set to maintain a constant speed of the driving-shaft of the wheel. The cost of generating, excluding interest and depreciation, as obtained by dividing the cost of labour and lubricants by the power demanded, is at present about ⅓d. per H.P. per hour, which could be furnished at a lower rate if more power were required. The 7½ H.P. hoist at one of the inclines has lately been replaced by a larger one of 25 H.P., geared so as to raise a load of 3,000lb. on an incline of 60deg. 275ft. per minute. In addition to the hoists an electrically-driven diamond prospecting drill has been in use since July, 1890. About 4,400 linear feet have been bored in twelve months at the rate of 1½ to 2in. per minute, or from 6 to 32ft. in the shift of eight hours, allowing for all delays, the average being about 15ft. per shift. The cost, including all expenses, has been 28s. 8d. per foot, or rather higher than was estimated, but it is thought that this price can be reduced. The full abstract of this Paper, from which these extracts were taken, is printed in the *Foreign Abstracts* of the Institution of Civil Engineers.

TRANSFORMER PREDETERMINATIONS.*

BY DR. J. A. FLEMING, M.A.

When an alternating E.M.F. is applied to the primary terminals of a transformer with open secondary circuit, or to the terminals of a simple choking coil, a small current is found to flow through the circuit, which is commonly, but rather erroneously, called the "magnetising current." It would be better to call this the "core' current, because its magnitude is very largely dependent upon actions taking place in the iron core. If a given conducting circuit, say an insulated copper wire, is wound on a bobbin non-inductively, and a certain alternating electromotive force applied to the ends of the circuit, it is a very easy matter to calculate the ampere value of the current, which will under these circumstances flow through the circuit. For the $\sqrt{\text{mean}^2}$† value of the current is at once obtained by dividing the $\sqrt{\text{mean}^2}$ value of the electromotive force by the ohmic resistance (R) of the wire. Again, suppose that this same circuit is wound inductively on a non-magnetic and non-conducting core or bobbin, the circuit has then a definite inductance (L), and the $\sqrt{\text{mean}^2}$ value of the current is obtained by dividing the $\sqrt{\text{mean}^2}$ value of the electromotive force by the impedance ($\sqrt{R^2 + p^2 L^2}$) of the circuit. In both these cases the energy supplied to the circuit is simply dissipated in the form of heat in the copper circuit. If, however, we suppose the copper circuit to be wound inductively on a magnetisable core, the problem of predetermining the current is not quite so simple. If the core is an ordinary iron core, then the energy supplied to the circuit is taken up in three ways—(i.) it is partly dissipated as heat in the copper circuit; (ii.) it is further dissipated by true magnetic hysteresis waste in the iron core; and (iii.) it is also wasted by reason of eddy currents set up in the core. A little reflection will show that the final result of both hysteresis and eddy current waste is equivalent, as far as energy waste is concerned, to closing a secondary circuit round an ideal non-hysteretic and non-conducting core. For we may imagine that the energy waste due to all the little eddy currents in the core and that due to the magnetic reversals to be imitated by simple resistance waste of a secondary current of a certain magnitude flowing in a closed secondary circuit wrapped round a perfectly ideal iron core in which these wastes do not go on. Now the effect of the secondary circuit, when closed, is to advance the phase of the primary current, and to increase its mean value. Hence, we may conclude that the total effect of the eddy currents and the hysteresis losses in an iron core upon the phase and magnitude of the so-called magnetising current is to increase its magnitude, and to bring it more into consonance with the impressed electromotive force as far as phase is concerned.

This action introduces further difficulties into the problem of predetermining the magnetising current of a transformer, or the current flowing through a choking coil when subjected to a certain alternating electromotive force of determined magnitude and frequency.

The general solution of this problem is a rather difficult matter; but we shall see that fortunately it may be easily solved for the cases most likely to occur in practice.

For the moment let us suppose ourselves dealing with a core in which both eddy current and hysteresis waste are so small as to be negligible, and consider, under these circumstances, how the magnitude of the current flowing through the primary circuit when the secondary circuit is open is to be determined.

Let R be the true resistance of the primary circuit, e the instantaneous value at any time of the impressed electromotive force acting on this circuit, and let i be the value of the current flowing through the circuit at that same instant. Also, let S be the cross-section of the magnetic circuit or of the core, and l be its mean length, and N the number of turns of the primary current round the core, and n the frequency of the alternations. Let b be the value of the induction density in the core at the instant of time considered.

We shall suppose the electromotive force to be a simple periodic function of the time, as usual, so that,

$$e = \mathrm{E} \sin p\,t.$$

If, then, μ is the value of the true magnetic permeability of the core at the instant when the induction density is b, the relation between i and b will be expressed by the equation,

$$4\pi \frac{\mathrm{N}}{l} \mu i = b \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

If instead of measuring i and b in C.-G.-S. or absolute units we measure i in amperes and b in gausses* per square centimetre then equation (1) becomes,

$$\frac{4\pi}{10^9} \frac{\mathrm{N}}{l} \mu i = b \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

These equations immediately follow from the facts that the magnetic force in the interior of a closed solenoid is by a fundamental principle equal in magnitude to 4π-times the absolute current turns per unit of length of the solenoid, and also that the quotient of induction density by permeability is a measure of the magnetic force in the interior of the core. From (2) it immediately follows that,

$$\frac{4\pi}{10^9} \frac{\mathrm{S\,N^2}}{l} \mu i = \mathrm{S\,N}\, b \quad . \quad . \quad . \quad . \quad . \quad (3);$$

and that

$$\frac{4\pi}{10^9} \frac{\mathrm{S\,N^2}}{l} \mu \frac{di}{dt} = \mathrm{S\,N} \frac{db}{dt} \quad . \quad . \quad . \quad . \quad (4).$$

Again, since e is the instantaneous value of the impressed electromotive force it follows that at every instant

$$e = \mathrm{R}\,i + \mathrm{S\,N} \frac{db}{dt} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5).$$

If the resistance of the copper circuit is very small then in practice it will nearly always happen that the magnitude of the resultant electromotive force, R i, is very small compared with the electromotive force of self-induction, viz, $\mathrm{S\,N} \frac{db}{dt}$. This will always be the case if the number of turns, N, of the wire wrapped in the core is considerable. Hence in general we may write (5)

$$e = \mathrm{S\,N} \frac{db}{dt}.$$

Hence from equation (4) it follows that

$$e = \frac{4\pi}{10^9} \frac{\mathrm{S\,N^2}}{l} \mu \frac{di}{dt};$$

but since $e = \mathrm{E} \sin p\,t$ we have

$$i = \frac{10^9\, l\, \mathrm{E}}{4\pi\, \mathrm{S\,N^2}\, \mu} \int \sin p\,t\, dt \quad . \quad . \quad . \quad . \quad (6);$$

and hence the maximum value of i, which we may write I, is given by the equation,

$$\mathrm{I} = \frac{10^9\, l\, \mathrm{E}}{8\pi^2\, \mathrm{S\,N^2}\, n\, \mu} \quad . \quad . \quad . \quad . \quad . \quad (7).$$

Before we can make any use of the above formula (7) we must have some notion of the value to be given to μ in the equation. It may be useful to put down here the values of μ obtained by Prof. Ewing for a very long, soft, and well-annealed iron wire, corresponding to certain values of the induction density in the wire. They are as follows:—

Lines of force per square centimetre. The induction density (B) in C.-G.-S. measure.	Corresponding value of the permeability (μ) for good soft wrought iron.
1,000	560
2,000	880
3 000	1,160
4,000	1,400
5,000	1,600
6,000	1,800
7,000	1,960
8,000	2,120
9,000	2,280
10,000	2,350

will give off two currents, which can be of the same strength, and both differing as regards phase. If an iron disc be inserted in the centre of the ring and be left free it will revolve. It is necessary in a motor of this type to have the phases as nearly in quadrature as possible, otherwise we get opposing forces, one tending to pull the armature round and another less powerful force tending to stop it. The efficiency of a motor constructed in this way is unimportant. The desire is simply to call attention to the way in which a very workable current splitter can be made that will produce a rotary magnetic field from simple alternating currents.

The Co-existence of Specific Inductive Capacity and Electrolytic Conductivity.—"The method which I used to measure the dielectric constant of mica at a high temperature," says M. Bouty in the *Comptes Rendus*, Vol. CXIV., No. 10, p. 533, "is applicable without essential modification to dielectrics having a small electrolytic conductivity. The capacity, c, of two rigidly fixed metal plates separated by air is taken, and the plates are then plunged into the dielectric conducting mass. By means of a torsion pendulum the circuit of the condenser is closed on a battery of electro-motive force E and negligible resistance, for a brief known time t, and the quantity of electricity, Q, is then received by a microfarad condenser." According to M. Bouty $Q = E\ (C + a\,t)$, where a and C are constants, $k = \frac{C}{c}$. Applying this method to benzine M. Bouty found $k = 2{\cdot}25$. According to Cohn, Arons, and Tereschin, k for distilled water is forty times greater than the square of the average index; and quite recently Rosa found $k = 75\ 7$. "Unfortunately," observes M. Bouty, "the conductivity of distilled water is far too great, and would necessitate the measurement of times t several hundred times less than the limit of accuracy of my pendulum (0 0001 second)." This objection does not, however, hold good for ice, which at 0° C., has a resistance some 12,000 times higher than water. Distilled water was, therefore, frozen, and a temperature of − 23° C. attained; $k = 78$. The very high specific inductive capacity of ice is therefore beyond question. On allowing the temperature of the ice to rise its conductivity, of course, increased, but its specific inductive capacity remained much the same. It follows from these experiments that dielectric power and electrolytic conductivity are capable of coexisting in the same body, which is conformable to Maxwell's views. Moreover, the specific inductive capacity varies but little under conditions in which the conductivity increases enormously. Water and ice have sensibly the same specific inductive capacity, whilst their conductivity may vary in the ratio of 1 to 10^5 or 10^6.

Statistics of Electric Lighting in Massachusetts.—The seventh annual report of the Board of Gas and Electric Light Commissioners of Massachusetts for the year ended June 30, 1891, has just been issued. The report shows that there were 131 companies under the supervision of the Board, 26 of which supply both gas and electric light; 58 only electric light. The results of the year's operations of the electric light central stations, compared with the year 1890, are as follows:—

	Year ending June 30. 1891.	1890.
Receipts	$2,440,350.65	$1,920,702.05
Expenses	1,735,206.13	1,340,814.60
Balance	$705,144.52	$579,887.45

The amount of net earnings of the electric light departments of gas companies was $110,871.40 in 1890; for 1891, $143,240.78. The net earnings of the electric companies in 1890, $469,016.05; in 1891 they were $561,903.74. In capitalisation the Edison Electric Illuminating Company, of Boston, heads the list with $1,263,500. The total valuation of the electric plants, as shown by the local assessors, was $2,035,160. Dividends were paid by 25 companies, amounting to $262,968. These ranged from a 10 per cent. dividend to one of 1 per cent. The Edison Illuminating Company of Boston paid 5½ per cent. The largest arc light company in the State is the Boston Electric Light Company, with 2,041 arcs. The largest incandescent lighting company is the Boston Edison, which supplies current to the equivalent of 90,000 8-c.p. lights from 64 dynamos. The total number of boilers in use in central stations is 216, engines 261, dynamos 591. Two plants are driven entirely by water-power. Five persons were injured during the year by electricity, one of them fatally. Of the various systems in use in the State the following are noted: Thomson-Houston, Westinghouse, Brush, Schuyler, American, Ball, Waterhouse, Sun, Weston, Electro-Dynamic Company, Arnoux Hochhausen, and Edison Municipal. Of these the Thomson-Houston was used by 69 electric lighting companies, the Westinghouse by 13, the Edison by 10, the Schuyler and American each by 6, the Waterhouse and Brush each by 5, the Ball by 3, the Edison Municipal by 2, and the Electro-Dynamic, Sun, Weston and Arnoux Hochhausen each by 1. The total length in feet of wire in use in the State was 24,632,523; of underground conduit, 219,580; of wire in conduit, 716,187.

Electric Mining in Colorado.—In a Paper recently read before the American Institute of Mining Engineers, Mr. M. B. Holl gives some interesting particulars with regard to the well-known electric plant at Aspen, Colorado. Power for hoisting on some steep inclines is obtained from a 50-H.P. 500-volt constant-potential Edison dynamo, driven by a Pelton wheel 5ft. in diameter, with an effective head of 63ft., placed 6,000ft. from the mouth of the tunnel. The hoisting engine at the inner end is a 7½ H.P. Sprague street-car motor-driving two drums. The working of this motor was so successful that a similar one has been placed at the head of another incline Each of these is designed to raise 250 tons on the incline of 60deg. for a length of 250ft. in 16 working hours during the day. The cost for repairs of the first motor, in addition to the small outlay in replacing commutator brushes from time to time, during three years' constant work, has been as follows:—

	£.	s.	d.
Replacing field magnet-coils	8	19	0
Rewinding one armature	16	13	0
Replacing commutators	15	12	0
Total repairs	£41	4	0

The first of the above items was due to the burning out of the insulation on the magnet-coils, the second from the bursting of the binding-wires on the armature, and the last from the wear between the commutators and the copper brushes originally employed. Recently the latter have been replaced by others of carbon, and since the change the motors have run without shaking, and the wear in the commutators is inappreciable. In the latter part of 1889 the company, which had previously been supplied with power from the Roaring Fork Electric Light and Power Company, erected its own generating plant. This has a capacity of 100 electrical H.P., produced by two 50 H.P. Thomson-Houston motor-type dynamos wound for a constant potential of 500 volts, each of which is driven by two Pelton water-wheels 42in. in diameter paired on the same shaft. A head of 80ft. of water, giving a pressure of about 35lb. per square inch at the foot of the main pipe, is obtained by a lander about 1,600ft. long, having a capacity of 1,000 cubic feet of water per minute. The speed of the wheels can be varied according to the requirements of the power by altering the direction of the impinging jets, for which purpose the delivery nozzles are mounted on a ball-and-socket joint, which is connected by a link-motion with a Woodward governor set to maintain a constant speed of the driving-shaft of the wheel. The cost of generating, excluding interest and depreciation, as obtained by dividing the cost of labour and lubricants by the power demanded, is at present about ⅓d. per H.P. per hour, which could be furnished at a lower rate if more power were required. The 7½ H.P. hoist at one of the inclines has lately been replaced by a larger one of 25 H.P., geared so as to raise a load of 3,000lb. on an incline of 60deg. 275ft. per minute. In addition to the hoists an electrically-driven diamond prospecting drill has been in use since July, 1890. About 4,400 linear feet have been bored in twelve months at the rate of 1½ to 2in. per minute, or from 6 to 32ft. in the shift of eight hours, allowing for all delays, the average being about 15ft. per shift. The cost, including all expenses, has been 28s. 8d. per foot, or rather higher than was estimated, but it is thought that this price can be reduced. The full abstract of this Paper, from which these extracts were taken, is printed in the *Foreign Abstracts* of the Institution of Civil Engineers.

TRANSFORMER PREDETERMINATIONS.*

BY DR. J. A. FLEMING, M.A.

When an alternating E.M.F. is applied to the primary terminals of a transformer with open secondary circuit, or to the terminals of a simple choking coil, a small current is found to flow through the circuit, which is commonly, but rather erroneously, called the "magnetising current." It would be better to call this the "core' current, because its magnitude is very largely dependent upon actions taking place in the iron core. If a given conducting circuit, say an insulated copper wire, is wound on a bobbin non-inductively, and a certain alternating electromotive force applied to the ends of the circuit, it is a very easy matter to calculate the ampere value of the current, which will under these circumstances flow through the circuit. For the $\sqrt{\text{mean}^2}$† value of the current is at once obtained by dividing the $\sqrt{\text{mean}^2}$ value of the electromotive force by the ohmic resistance (R) of the wire. Again, suppose that this same circuit is wound inductively on a non-magnetic and non-conducting core or bobbin, the circuit has then a definite inductance (L), and the $\sqrt{\text{mean}^2}$ value of the current is obtained by dividing the $\sqrt{\text{mean}^2}$ value of the electromotive force by the impedance ($\sqrt{R^2 + p^2 L^2}$) of the circuit. In both these cases the energy supplied to the circuit is simply dissipated in the form of heat in the copper circuit. If, however, we suppose the copper circuit to be wound inductively on a magnetisable core, the problem of predetermining the current is not quite so simple. If the core is an ordinary iron core, then the energy supplied to the circuit is taken up in three ways—(i.) it is partly dissipated as heat in the copper circuit; (ii.) it is further dissipated by true magnetic hysteresis waste in the iron core; and (iii.) it is also wasted by reason of eddy currents set up in the core. A little reflection will show that the final result of both hysteresis and eddy current waste is equivalent, as far as energy waste is concerned, to closing a secondary circuit round an ideal non-hysteretic and non-conducting core. For we may imagine that the energy waste due to all the little eddy currents in the core and that due to the magnetic reversals to be imitated by simple resistance waste of a secondary current of a certain magnitude flowing in a closed secondary circuit wrapped round a perfectly ideal iron core in which these wastes do not go on. Now the effect of the secondary circuit, when closed, is to advance the phase of the primary current, and to increase its mean value. Hence, we may conclude that the total effect of the eddy currents and the hysteresis losses in an iron core upon the phase and magnitude of the so-called magnetising current is to increase its magnitude, and to bring it more into consonance with the impressed electromotive force as far as phase is concerned.

This action introduces further difficulties into the problem of predetermining the magnetising current of a transformer, or the current flowing through a choking coil when subjected to a certain alternating electromotive force of determined magnitude and frequency.

The general solution of this problem is a rather difficult matter; but we shall see that fortunately it may be easily solved for the cases most likely to occur in practice.

For the moment let us suppose ourselves dealing with a core in which both eddy current and hysteresis waste are so small as to be negligible, and consider, under these circumstances, how the magnitude of the current flowing through the primary circuit when the secondary circuit is open is to be determined.

Let R be the true resistance of the primary circuit, e the instantaneous value at any time of the impressed electromotive force acting on this circuit, and let i be the value of the current flowing through the circuit at that same instant. Also, let S be the cross-section of the magnetic circuit or of the core, and l be its mean length, and N the number of turns of the primary current round the core, and n the frequency of the alternations. Let b be the value of the induction density in the core at the instant of time considered.

We shall suppose the electromotive force to be a simple periodic function of the time, as usual, so that,

$$e = \mathrm{E} \sin p\,t.$$

If, then, μ is the value of the true magnetic permeability of the core at the instant when the induction density is b, the relation between i and b will be expressed by the equation,

$$4\pi \frac{\mathrm{N}}{l} \mu i = b \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

If instead of measuring i and b in C.-G.-S. or absolute units we measure i in amperes and b in gausses* per square centimetre then equation (1) becomes,

$$\frac{4\pi}{10^9} \frac{\mathrm{N}}{l} \mu i = b \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

These equations immediately follow from the facts that the magnetic force in the interior of a closed solenoid is by a fundamental principle equal in magnitude to 4π-times the absolute current turns per unit of length of the solenoid, and also that the quotient of induction density by permeability is a measure of the magnetic force in the interior of the core. From (2) it immediately follows that,

$$\frac{4\pi}{10^9} \frac{\mathrm{S\,N^2}}{l} \mu i = \mathrm{S\,N}\, b \quad . \quad . \quad . \quad . \quad . \quad (3);$$

and that

$$\frac{4\pi}{10^9} \frac{\mathrm{S\,N^2}}{l} \mu \frac{di}{dt} = \mathrm{S\,N} \frac{db}{dt} \quad . \quad . \quad . \quad . \quad (4).$$

Again, since e is the instantaneous value of the impressed electromotive force it follows that at every instant

$$e = \mathrm{R}\,i + \mathrm{S\,N} \frac{db}{dt} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5).$$

If the resistance of the copper circuit is very small then in practice it will nearly always happen that the magnitude of the resultant electromotive force, R i, is very small compared with the electromotive force of self-induction, viz, $\mathrm{S\,N} \frac{db}{dt}$. This will always be the case if the number of turns, N, of the wire wrapped in the core is considerable. Hence in general we may write (5)

$$e = \mathrm{S\,N} \frac{db}{dt}.$$

Hence from equation (4) it follows that

$$e = \frac{4\pi}{10^9} \frac{\mathrm{S\,N^2}}{l} \mu \frac{di}{dt};$$

but since $e = \mathrm{E} \sin p\,t$ we have

$$i = \frac{10^9\, l\, \mathrm{E}}{4\pi\, \mathrm{S\,N^2}\, \mu} \int \sin p\,t\, dt \quad . \quad . \quad . \quad . \quad (6);$$

and hence the maximum value of i, which we may write I, is given by the equation,

$$\mathrm{I} = \frac{10^9\, l\, \mathrm{E}}{8\pi^2\, \mathrm{S\,N^2}\, n\, \mu} \quad . \quad . \quad . \quad . \quad . \quad (7).$$

Before we can make any use of the above formula (7) we must have some notion of the value to be given to μ in the equation. It may be useful to put down here the values of μ obtained by Prof. Ewing for a very long, soft, and well-annealed iron wire, corresponding to certain values of the induction density in the wire. They are as follows:—

Lines of force per square centimetre. The induction density (B) in C.-G.-S. measure.	Corresponding value of the permeability (μ) for good soft wrought iron.
1,000	560
2,000	880
3 000	1,160
4,000	1,400
5,000	1,600
6,000	1,800
7,000	1,960
8,000	2,120
9,000	2,280
10,000	2,350

If we apply the values of μ taken from the above table in conjunction with the equation (7) to calculate the maximum value of the primary current on open secondary circuit for any transformer of the closed magnetic circuit type, we shall generally, but not always, find that the so calculated value of the current is less than the observed value. In many cases, however, the formula will give us a fair approximation to the maximum value of the so-called magnetising current. Thus, for example, take the case of the small Westinghouse transformer employed in Ryan's experiment and referred to in *The Electrician* of January 22nd. The mean length (l) of the magnetic circuit is 31 centimetres, the cross section (S) 63 square centimetres, and the number of turns (N) of the primary circuit 675. The frequency (n) was 138, and the value of E, 1,400 volts. Insert these values in (7) and we have

$$I = \frac{10^9 \times 31 \times 1400}{8\pi^2 \times 63 \times (675)^2 \times 138 \times \mu} = \frac{139}{\mu} \quad . \quad . \quad (8).$$

The maximum value of the induction density was in this case nearly 4,000. Corresponding to B = 4,000, the static permeability of soft iron is 1,400. If we put $\mu = 1{,}400$ in (8) we have I = ·1 ampere, whereas the maximum value of the primary current on open secondary was 0·21 ampere. The quality of the iron may, however, have been inferior. Moreover, the eddy current and hysteresis loss were in this case considerable. If we give μ the value of 700, then the calculated and observed values of I would agree. An examination of many other cases, however, shows that this equation (7) will give a fair approximation to the observed current.

Thus Mr. Evershed has given* the data of a 30 horse-power Goolden-Ravenshaw Transformer as follows:

Mean length of magnetic circuit	145 cms.
Cross-sectional area of the magnetic circuit	95 sq. cms.
Total volume of iron in core	13,700 c.c.
Frequency	70
Primary turns	680
Secondary turns	34
Primary volts	2,000
Secondary volts	100
Primary circuit resistance	·97 ohm.
Secondary circuit resistance	·003 ohm.
Thickness of core plates	·05 cm.
Full load output	22,400 watts.
Maximum value of the induction density during the cycle	10,000 C.-G.-S. units.
Maximum value of the primary E.M.F.	2,800 volts.

Corresponding to B = 10,000, we have $\mu = 2{,}350$. Hence, substituting the proper values for this transformer in equation (7), we have

$$I = \frac{10^9 \times 145 \times 2800}{8\pi^2 \times 95 \times (680)^2 \times 70 \times 2350} = \cdot 7 \text{ ampere.}$$

Hence the maximum value of the magnetising current is ·7 ampere and the $\sqrt{\text{mean}^2}$ value should be nearly ·5 ampere. The actual value is given as half an ampere. Let us take another instance. The following are the data of a 10 horse-power Ganz Transformer of the closed magnetic circuit type:

Mean length of magnetic circuit		94 cms.
Area of cross section of magnetic circuit		130 sq. cms.
Total volume of iron in core		12,180 c.c.
Weight		95,000 grammes.
Number of primary turns, N_1		1,080
Number of secondary turns, N_2		60
Resistance of primary circuit.....		4·2 ohms.
Resistance of secondary circuit		·0135 ohm.
Total weight of copper in transformer...		40,000 grammes.
Frequency		42·5 ∽
Primary electromotive force	effective value...	1,926 volts.
	maximum value	2,696 volts.
Secondary electromotive force	effective value...	105 volts.
	maximum value	147 volts.
Maximum value of induction density in core.....		7,600 C.-G.-S.
Observed value of the primary currents on open secondary circuit, effective value		·17 ampere.

* See the series of articles on "The Magnetic Circuit of Transformers" in *The Electrician* for February and March, 1891, Vol. XXVI.

Corresponding to a maximum induction of 7,600 C.-G.-S. units the value of the permeability is about 2,000. Hence we should have from the formula the following as a predetermined value for the magnetising currents:—

$$I = \frac{10^9 - 2696}{8\pi^2 - 130 - (1080)^2 - 42{\cdot}5 - 2000} = \cdot 243.$$

Hence the calculated maximum value of the magnetising current is about ·24 ampere, and the effective value or $\sqrt{\text{mean}^2}$ value is ·17 ampere, which exactly agrees with observation.

In the case of a number of other closed circuit transformers, all of which are worked at an induction density of about 4,000 or 5,000 C.-G.-S. which have been examined by the author, the above rule gives a very tolerable approximation to the observed magnetising current. In these cases it was found that by taking values for μ, about 200 less than those given by Ewing for the softest wrought iron, a very close predetermination to the value of the open circuit current could be obtained. The rule must not be, however, applied indiscriminately, and is only valid for cases of closed circuit transformers, having cores of good soft iron well laminated, and for cases in which the magnetisation of the iron is not carried up over the "knee" of the magnetisation curve.

It could not be applied, for instance, in the case of a solid wrought or cast-iron core, for in this case the resulting calculated value of I would be very far below the real or observed value. Such a case is obviously not really that of an open circuit transformer at all, for the eddy currents set up in the core are true secondary currents of considerable magnitude.

The equation (7) may be reduced to another form by expressing the value of μ as a function of B. As the permeability μ varies with the induction B, we may express μ approximately as a function of B, of the form

$$\mu = \alpha \, B^{\beta} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8),$$

where α and β are constants. To find the values to be given to α and β we may proceed thus: Taking logarithms of both sides we have

$$\log \mu = \log \alpha + \beta \log B \quad . \quad . \quad . \quad . \quad . \quad (9).$$

If we plot this curve, taking the values given by Ewing for μ and B, we find that it is approximately a straight line, and that we have very nearly

$$\alpha = 5{\cdot}6, \ \beta = \frac{2}{3},$$

and hence

$$\mu = 5{\cdot}6 \, B^{\frac{2}{3}} \quad . \quad . \quad . \quad . \quad . \quad (10).$$

Calculating by this formula values of μ, and comparing them with the observed, we find a fair general agreement, especially between B = 1,000 and B = 6,000.

B.	Observed value of μ.	Value calculated from equation $\mu = 5{\cdot}6 \, B^{\frac{2}{3}}$.
1,000	560	560
2,000	880	890
3,000	1,160	1,165
4,000	1,400	1,410
5,000	1,600	1,612
6,000	1,800	1,848
7,000	1,960	2,049
8,000	2,120	2,240
9,000	2,280	2,420
10,000	2,350	2,595

From B = 1,000 to B = 5,000 the constant α has exactly the value 5·6, but from 5,000 to 10,000 the observed and calculated values of μ agree better if we take $\alpha = 5{\cdot}3$.

If we take $\alpha = 5$ and $\mu = 5 \, B^{\frac{2}{3}}$, and insert this value of μ in equation (7), we can reduce it to another useful form for practical work.

For taking equation (1), page 653, viz.,

$$4\pi \frac{N}{l} \mu \, i = b \quad . \quad . \quad . \quad . \quad . \quad (11),$$

and putting $\mu = 5 \, b^{\frac{2}{3}}$ we have

$$20\pi \frac{N}{l} i = b^{\frac{1}{3}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (12).$$

Digitized by Google

If we put I for the maximum value in amperes of the primary current of the transformer in open secondary circuit, and B for the maximum value of the corresponding maximum induction density in C.-G.-S. measure, and E for the maximum value of the impressed primary electromotive force, then we reduce the equation (12) to the form

$$\frac{44}{7}\frac{N}{l}I = B^{\frac{1}{2}} = (p\,S\,N\,E\,.\,10^8)^{\frac{1}{2}} \quad . \quad . \quad . \quad (13),$$

and this last can be written

$$I = \frac{40\,l}{N}\left(\frac{E}{n\,S\,N}\right)^{\frac{1}{2}} \quad . \quad . \quad . \quad . \quad (14).$$

From equation (14) we can deduce very approximately the maximum value, I, of the primary "magnetising current" of a transformer when we are given the maximum value E of the primary electromotive force, and the dimension, section S and mean length l of the magnetic circuit, the number of turns N of the primary coil, and the frequency n.

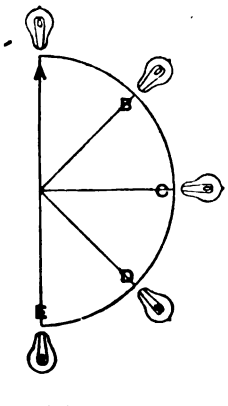
The above equation (14) is, like equation (7), only applicable to closed magnetic circuit transformers with good soft iron cores, well laminated, and in which the ohmic resistance of the wire circuit is insignificant in comparison with the impedance of that circuit. But under these circumstances, when eddy current loss is small, the formula (14) is useful for calculating the open circuit current both for transformers and for choking coils.

(To be continued.)

THE BEST EFFICIENCY FOR INCANDESCENT LAMPS.*

BY ANDRÉ LARNAUDE.

Improvements in the manufacture have brought down the price of the incandescent lamp from 5 francs to less than 2 francs. With regard to the energy expended per unit of light, manufacturers have followed the requirements of consumers, who attach prime importance to the life of the lamps. The question of the use of economical lamps certainly merits the attention of electricians; and if this has



not hitherto been obtained for it, it is probably because central-station managers have been employed in securing the regular working of their stations, or because there is a lack of information. Experiments relating to the life and working conditions of incandescent lamps are very difficult to carry out on account of the precautions which it is necessary to take, and the amount of time required. In spite of improvements in manufacture we have not yet succeeded in turning out lamps having a definite life, and in the same batch of lamps samples are frequently found the life of which varies by 50 per cent. Experiments, therefore, that have any practical value should relate to as many lamps as possible. Some experiments which I carried out in the laboratory of the Compagnie Générale des Lampes Incandescentes related to batches of 50 to 100 lamps taken at random.

In order to imitate, as far as possible the conditions of practice, the lamps were placed in a framework, as shown in the accompanying figure, the lamps being in different position from the point of view of mechanical strain. These experiments showed that the positions B and C were very bad for thin, long filament lamps, such as 10 c.p. lamps taking more than 100 volts.

* From *Le Génie Civil*.

The following table relates to a 16 c.p. 100-volt lamp, taking 3·7 watts to the candle:—

Lamp hours.	Pougies décimales.
0	16·0
200	15·5
400	15·0
600	14·3
800	13·4
1,000	11·5

I am inclined to think that when the amount of light emitted by a lamp has decreased by 15 per cent. below its original value, it should be considered *hors de combat*.

Acting on this basis, we may rely upon the following lives:—

4·0 watts to the candle	1,000 hours.
3·5 " " "	700 "
3·0 " " "	350 "
2·5 " " "	150 "

I will now give a table showing the cost of a 16 c.p. lamp-hour working under various conditions. In order to examine the different cases which occur in practice I have varied the price of the kilowatt hour from 0·25 franc to 1 franc, and have assumed the cost of the lamp to be 2 francs.

Price of kilowatt hour in francs.	Price of the 16-candle lamp-hour.			
	4 watts.	3·5 watts.	3 watts.	2·5 watts.
0·25	0·018	0·017	0·018	0·0235
0·50	0·034	0·031	0·030	0·0335
0·75	0·050	0·045	0·042	0·0135
1·00	0·066	0·059	0·054	0·0535

We see from this table that, even supposing the cost of electricity to be as low as 0·25 franc for the kilowatt hour, it is not advisable to employ a 4-watt lamp. Nevertheless, the small manufacturer, who has cheap power, demands long-lived lamps. I am inclined to think that he is right, and that because of the irregularities which generally occur in the pressure these variations have a more appreciable effect on the life of the lamp, the closer it is running to its most economical figure. Although it is not possible to bring this factor into our calculations it should be taken into account, especially in installations where electricity is obtained at a cheap rate, and in which the cost of the lamp renewals forms a large proportion of the total expense.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-NIGHT) FRIDAY, April 22nd.

INSTITUTION OF CIVIL ENGINEERS.

7.30 p.m. Students' Meeting. Paper to be read: "The Speed and Power of Locomotives." By Edmund L. Hill, Stud.Inst.C.E.

TUESDAY, April 26th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read: "Electric Light Measuring Instruments." By James Swinburne. The meeting will be adjourned at 9:30 p.m., when the President and Council will hold a reception in the Libraries.

WEDNESDAY, April 27th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Egyptian Agriculture." By Prof. Robert Wallace.

THURSDAY, April 28th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Chemistry of Gases." By Prof. Dewar, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Paper to be read: "Notes on the Light of the Electric Arc." By A. P. Trotter, B.A., member. (Illustrated by an experiment.)

FRIDAY, April 29th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Physiology of Dreams." By Dr. B. W. Richardson, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

STEEL-PLATE PORTRAITS

Of W. H. Preece, F.R.S.; Michael Faraday; Sir John Pender, K.C.M.G.; Sir William Thomson, F.R.S. (Past-President of the Institution of Electrical Engineers); C. H. B. Patey, C.B. (Late Secretary of Telegraphs, G.P.O.); Dr. John Hopkinson, F.R.S. (Past-President of the Institution of Electrical Engineers); Dr. Oliver J. Lodge, F.R.S., Prof. William Crookes, F.R.S. (Past-President of the Institution of Electrical Engineers); Willoughby Smith (out of print); Prof. von Helmholtz and Prof. W. E. Ayrton (President of the Institution of Electrical Engineers), have been issued as Supplements to "THE ELECTRICIAN."

A few Copies of these admirably-executed Steel Engravings can be supplie price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, 4s. 6d, carriage paid (U.K.)

THE TELEGRAPH AND THE ARMY.

Pressure on our space has prevented until now the publication in these pages of Major BERESFORD'S Paper, read before the Royal United Service Institute in the month of February. The subject is of permanent interest, however; and we make no apology for drawing attention to it here, even after this lapse of time. Although entitled "The Telephone at Home and in the Field," Major BERESFORD'S review extended beyond the use of the appliance technically known as the telephone, and of course had a more general reference to electrical signalling on active service. Under this head the telephone can be regarded only as one form of telegraph, or rather as a particular piece of apparatus employed for telegraph signalling. In the service of the Army it matters not in what manner this marvellous little instrument is manipulated, whether by itself as a simple magnetic telephone, or in company of a microphonic transmitter, or even in hybrid conjunction with any of the ordinary telegraph signalling keys. Not being hedged round by any of those proprietorial restrictions which have hindered its free development in the commercial world, the telephone in the Army has free play to show what it is capable of doing in all sorts of circumstances, and under every conceivable condition. Ingenuity and inventiveness have done more for it in the Army probably than anywhere else; and we owe to officers of the Royal Engineers many devices for military telephonic working that will prove welcome to civilian lines whenever they are completely emancipated from the chains of the Patent Office.

It will be seen from the abstract of his Paper which we publish this week that Major BERESFORD has described a

Digitized by Google

number of these devices and applications, chiefly relating to the telephone; but as he found himself obliged to make comparisons between systems of which the telephone formed part, and others into which the telephone does not enter at all, yet every one of them useful and even necessary for military purposes, it seems to us that his Paper would have been more correctly described by the title we have ventured to place at the head of this article. Comparisons of the kind we allude to are apt to bring into disrepute any given mode of signalling; for example, the telephone as such, the Morse sounder as such, or the Morse printer, or flag signalling, any one of which may be condemned in given circumstances, but all of them of pre-eminent utility with favourable surroundings. Not only are they useful in themselves, but they can be all efficiently combined; and the electrical series are, moreover, capable of being interchanged or worked the one into the other. A Morse sounder may be worked into a Morse printer, or *vice versâ*, just as either can be worked into a telephone, though unfortunately not in the reverse order. A telephone line, however, in military operations, can dispense with the microphone at one end, and often at both ends. And where there is a break in the continuity of the line, flag-signalling, preferably by the Morse code, may play an important part in filling up the gap.

We have laid some stress on these obvious facts, because of the tendency to extol one mode of signalling to the disparagement of another, and to map out too precisely, as we think Major Beresford has done, the functions of the several systems. We feel sure that all those nice considerations which go to recommend this or that pattern of instrument would be blown to the winds with the first puff of powder, when the chief thought would be how to utilise the apparatus nearest to hand. The gallant lecturer knows this better probably than we do; but he seems to be a little too fastidious, too much the man of peace manœuvres in the matter of insulation with regard to the instrument upon which he is discoursing, when in reality his own branch of the army was the first to demonstrate how superbly superior to insulation that instrument is. For main lines of communication as a talking instrument, the telephone would not be of much service, he says, because it would require double wires "if on the same poles as other lines." But lines of communication are, it may be hoped, sometimes in the enemy's country; and in that case we need hardly provide against "other lines" being left for our use; and we don't suppose that any commanding officer would object to keep up his communications by means of a telephone wire cast on the ground, with no insulation to speak of, and no wires to keep it company, because "it would not carry the traffic we were accustomed to"—meaning, we suppose, officers' telegrams to their friends at home, and the inordinate despatches of importunate special correspondents. It is a relief to learn, in this relation, that we have in the British Army, as in the Belgian and other armies, an appliance by means of which the telephone can be used for speaking purposes over lines worked simultaneously by Morse sounders or printers. Given the sounder or printer, all well and good; what we desire to emphasise is the possibility of dispensing with them, afforded by the simpler, less costly, more mobile, and more sensitive instrument. It should never be forgotten that the telephone will give out intelligible signals, and even audible speech, under conditions which render all other forms of telegraph dumb.

Major Beresford has done more excellent service in pointing out the saving in men which would result from greater completeness of telegraph equipments, including, of course, telephones, than the Army at present can boast of. The work of many men's legs can be spared by the erection of a single line of wire; and he argues further that telegraphic communication with the chief points of an outpost line would reduce the number of men required for outpost duty. From this he proceeds to advise the use of telegraphy in the cavalry service—a branch of Her Majesty's Army which is at present unprovided with this invaluable adjunct of warfare. Here we are led to remark that both as regards the kind of apparatus employed and the regiments to use them, the question is chiefly one of finding competent signallers. It signifies very little indeed what mode of signalling has to be resorted to so long as you can find the right men to do it. More signallers are needed, and under a short-service system the supply has to be continually kept up. We suspect that nothing like the right number or right quality of men are being trained for this highly essential arm of the service. In the last Egyptian war the Post Office rendered invaluable help by lending volunteers who were expert telegraphists and who remained afterwards in the Army Reserve. But these men's time has now probably expired, and their places may have to be filled, perhaps not so easily. Equipment is a most important factor; and by all means get as much of it as a parsimonious country will grant; but of not less importance are the men—men who can turn their hands and ears to anything electrical—without whom all these ingenious and costly appliances will be limited and crippled in their usefulness, and sometimes of no use whatever.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(*Continued from page 636.*)

8. **Types of Cable.**—While the ship is engaged in picking up it will be well to examine the different types of cable with which we have to deal. If out some distance at sea, it will be the deep-water types of cable we shall meet with, which are the smallest size of any, being only about $\frac{3}{4}$in. diameter. Nearer shore, in depths of from 30 to 250 fathoms, we shall come across a heavier type of cable, about $\frac{7}{8}$ to 1in. diameter; and close in shore, from the landing point to five or ten miles out, we shall find a very large and heavy type of cable known as the shore end, which is specially protected to withstand the constant rolling and friction caused by the tidal wash and being fouled or lifted by ships' anchors. This type is generally in three different sizes, varying from about $1\frac{1}{4}$in. to 2in., or more, in diameter, the largest being used close in shore. Seven leading types of cable as manufactured by the Telegraph Construction and Maintenance Company are represented in Fig. 27, as approximately as possible to actual size.

In all these types the central conductor is a strand of seven copper wires insulated by a coating of gutta-percha, and further protected, outside the percha, by a serving of brass ribbon or tape, to prevent the submarine boring animal, the toredo, from penetrating into the insulation. These minute animals, which exist in the Atlantic Ocean and in eastern seas, and have recently been traced quite close to our shores, settle upon the cable, and after forcing their way in between the sheathing wires, make for the core. The marks on the surface of the percha where the boring has been begun are blotchy and irregular, of about $\frac{1}{8}$in. diameter, but the hole pierced through the percha is less than half this size. Such attacks are frequently made in many places within a length of five miles, making the true position of fault very difficult to locate. The brass sheathing, first introduced by Mr. H. Clifford, engineer to the Telegraph Construction and Maintenance Company, is a most successful preservative against the depredation of these animals. It is necessary to lay an intermediate serving between the gutta-percha and the brass tape, so that the surface of the percha cannot be injured in any way by the metal. Some manufacturers put on a serving of tape over the percha. The

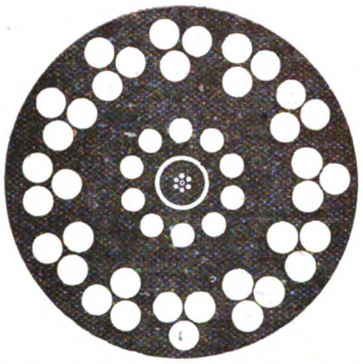
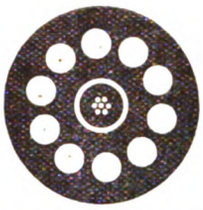
Silvertown Company put on a serving of loose spun linen, composed of 52 separate strands laid together, and so forming a perfectly flat and smooth surface on which to wind the brass tape.

The conductor, taken together with its insulating coating, is technically known as "the core." In the old cables as much as 300 or 400lbs. each of copper and gutta-percha per knot were used in the core; but in modern cables it is more general to use between 100 and 250lbs. The actual and relative weights of copper and gutta-percha used in different parts of the world vary to some extent, and there is some difference also in the practice of different cable companies. In the cables down the west coast of Africa there are, at least, three dimensions of core used with conductors of a fraction over 7, 9, and 11 ohms resistance per knot at standard temperature, and weighing 170, 130, and 107lbs. per knot respectively, while the gutta-percha covering to these cores weighs, respectively, 170, 130, and 140lbs. per knot.

Fig. 27.

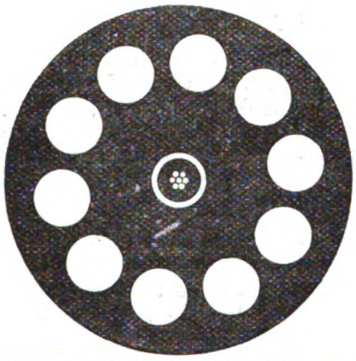


Shore end.—Type AA. (Anchorages to 30 fathoms.)



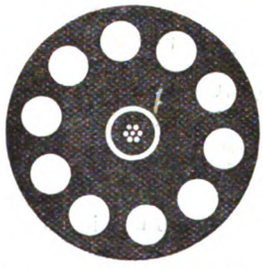
Intermediate.—Type B. (30 to 100 fathoms.)

Intermediate.—Type B'. (100 to 250 fathoms.)

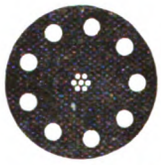


Shore end.—Type A. (To 30 fathoms.)

Deep Sea.—Type D. (200 to 1500 fathoms.)



Shore end.—Type E. (To 60 fathoms.)



Deep Sea.—Type C. (1000 to 3000 fathoms.)

Each complete cable between two places is made up with lengths of shore-end, intermediate and deep-sea types of cable according to the existing depths of water. The heaviest of all is the shore-end type, used for the locality of anchorages. Those portions of harbours in which ships regularly cast anchor are, of course, rigorously avoided where possible in laying. The usual practice is to select a suitable landing place, clear of rocks, and situated a few miles away from the anchorage ground of the port. But where the cable must be landed close to a harbour, a circuitous route is chosen for it until it is out of reach of the general anchorage ground of vessels, and its position is indicated at points along the harbour by red mark-buoys, intelligence to this effect being duly notified to the shipping. The shore end of the Cape cable is laid in this manner round the extreme circuit of Table Bay, the end being landed close to the old jetty at the bottom of the main thoroughfare. But accidents to cables by ships' anchors are more frequent a little distance out of the harbour than in the regular anchorages. Sailing ships tacking into port will cast anchor, if the wind falls, to prevent themselves drifting back with the tide, and it not unfrequently happens that cables are hooked, dragged and raised by these ships, with the result that they are either fractured or so badly fouled and kinked as to cause a dead earth on the line. Most vessels are aware of the fact if they have fouled a cable, whether they have raised it to the surface or not; and some captains report such an occurrence immediately they get in port.

It will be seen from the engraving that the heavy type of shore-end, known as type AA, is protected by an outside sheathing of 12 strands of three wires each, water laid, and an inner sheath of 10 wires. This type is used in harbours near anchorages in depths up to about 30 fathoms, and weighs from 16 to 20 tons per mile. Type A is also a shore-end with a sheathing of 10 wires, and is used in shallow water. Type E is a shore-end for slightly deeper water, up to 60 fathoms, and is protected by 10 sheathing wires. Of the intermediate types two are shown: type B for 30 to 100 fathoms, with 10 sheathing wires, and type B' with 12 smaller sheathing wires, for depths up to 500 fathoms. The deep sea types are type D with 12 small sheathing wires, for depths up to 1,500 fathoms, and type C with nine sheathing wires for the greatest depths known. These weigh only about 2½ tons per mile. The armouring of sheathing wires is designed to give the cable a mechanical strength some three or four times that required to bear its own weight of suspension in the deepest water. Thus, if a cable were to be laid in 2,000 fathoms, it would be made of sufficient tensile strength to support from 6,000 to 8,000 fathoms of its own weight in water, equivalent to a breaking strain of about seven or eight tons per square inch. In order to protect the iron or steel sheathing wires from corrosion, it used to be the practice to cover them with hemp. But on picking up cables so covered, the effects of corrosion are observed to have gone through the hemp and destroyed the fibre, and it is now the general practice to tape each of the wires separately, the tape being sometimes prepared with stearine. The whole is then covered with a compound of gutta-percha and Chatterton's compound (one part each of Stockholm tar and resin, and three parts of gutta-percha).

It may be of interest to show how the above types of cable are distributed on long cables, both in deep and shallow water. As an instance of one, we may cite the cable connecting Cape Town with Mossamedes on the West Coast. Starting from the Cape Town end, this cable consists of the following lengths, spliced together, of the above types:—

6	knots of	type	A	1·5	knots of	type	B
13	,,	,,	E	62·5	,,	,,	B'
41	,,	,,	B	931	,,	,,	D
167·7	,,	,,	B'	2	,,	,,	B
98	,,	,,	D	1	,,	,,	A
58·6	,,	,,	B'	1	,,	,,	AA

The total length being thus a little over 1,383 knots. At a distance of 384 knots from Cape Town a T-piece is jointed to this cable leading to an intermediate station on the coast, and the cable is accordingly strengthened at this point by a short length of type B. The depth in which type D in this cable is laid is about 1,000 fathoms.

As an instance of a shallow-water cable we may take the cable laid along the coast of the Gulf of Guinea, between Accra on the Gold Coast and Sierra Leone. This cable is 1,019 knots in length, and laid in water not more than 720 fathoms in the deepest part, the average depth being about 100 fathoms. The lightest type used in this cable is type B', the different types being spliced together in the following lengths, starting from Sierra Leone:—

5	knots of	type	A	18·4	knots of	type	B
5	,,	,,	E	3	,,	,,	E
46·8	,,	,,	B	2	,,	,,	AA
939	,,	,,	B'				

Digitized by Google

These particulars, noted down in the paying-out log at the time the cable is first laid, together with a chart of the course of the cable, are all spread out in the chart-room on board ship at the time of repairs, so that every information about the cable is at hand. The paying-out log is an abstract of each position, or change of course, with calculated distances and lengths of cable paid out, &c. The details recorded in this log are of a series of positions, giving the latitude, longitude, and true course of the vessel at each position during the laying of the cable. The true distances between each position are entered in the log and added together as the ship proceeds, while the actual lengths of cable paid out between each position are also recorded. These respective distances and lengths so added together furnish at once the amount of cable paid out up to any position and the corresponding distance travelled by the ship, the difference between these distances giving the slack. The actual and percentage amount of slack paid out between positions is also recorded, together with these figures for the whole cable. The percentage of slack on cables laid in depths exceeding 1,500 fathoms may amount on the average to 10 per cent. or more, but for average depths the slack is about 6 per cent. The positions of the various splices and the types of cable at the splices are also recorded, and these records are altered according as new splices and lengths of cable are added by subsequent repairs.

(To be continued.)

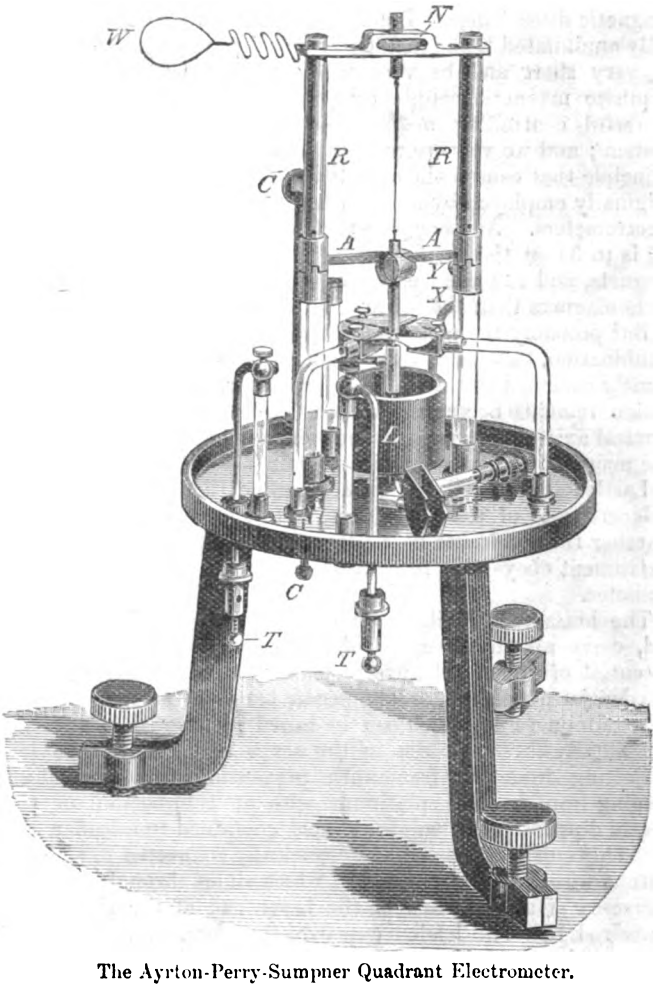
IMPROVED QUADRANT ELECTROMETER.*

The first condition to be fulfilled in designing an electrometer, indeed we venture to think in designing any electrical measuring instrument, consists in supporting all the working parts from the base, so that on removing the cover, all the parts can be got at and adjusted in position. We therefore commenced by turning Sir William Thomson's electrometer upside down, so to say, supporting the quadrants, needle, charging rod, &c., from the base, and using the glass shade which covers up our instrument as the Leyden jar.

The engraving shows an instrument with this glass shade removed, the springy wire W being for the purpose of making connection with the interior of the Leyden jar; and it will be seen that every part of the interior can be easily got at without interfering with the adjustment and without having to first clamp the needle. Further, not merely are the insulating stems that support the needle and the quadrants protected from dust and moisture, when the cover is on, but also the insulating stems that support the brass terminals T, T, and the charging rod C C. Hence there are no exposed ebonite stems requiring daily rubbing to remove dust and moisture, an operation that not unfrequently electrifies them, resulting in a slow charging of the quadrants when they are insulated. When the instrument is not in use the holes in the base plate through which pass the terminal rods T, T are closed by means of brass plugs sliding on the terminal rods and pushed up from below.

In the White form of electrometer the charging rod can be electrically disconnected from the interior by the short ebonite tube, which holds it, being turned by the fingers. To do this, however, the ebonite tube must be tightly grasped in one's fingers, and as they are necessarily chemically dirty, there is the possibility of the Leyden jar being partially discharged in the act of disconnecting the charging rod. This objection is entirely overcome with the arrangement which we have adopted for the charging rod in the improved quadrant electrometer. At the top of a glass rod is cemented a cap, to which is attached a piece of brass, to the lower end of which is fixed a pivot, round which the charging rod C C can turn. The ball C at the upper end of this rod is made of lead, and its weight causes the rod to remain in either of two positions. When in one position the ball C is in electric contact with the needle, guard-tube, and the interior of the Leyden jar, the area of contact being increased by the bending of the little piece of flat spring fastened to the ball. The Leyden jar can now be charged, and at the moment that the right amount of charge has been given, the charging rod C C is tilted over into the other position. This tilting over is easily done by pushing the lower end of the rod with the electrophorus, if an electrophorus be used to charge with, or by means of a glass rod, or by slightly pulling the wire attached to the binding screw at the lower end of C C, if such a wire be used to charge through.

When this electrometer is employed for alternating-current work it is desirable to connect the binding screw B by means of a fine wire with a binding screw attached to the interior of the instrument, so that the electric contact between the charging rod and the interior of the instrument (which should be very good for very rapid reversals of the charge) does not depend solely on the pressure of the leaden ball at the top of C C. It is also desirable, when an electrometer is employed for measuring a rapidly alternating potential difference, that



The Ayrton-Perry-Sumpner Quadrant Electrometer.

the electric connection between the electrodes and the quadrants should be far better than can be obtained with the comparatively slight pressure that exists between the ends of the electrodes and the quadrants in the White form of instrument; hence in the improved quadrant electrometer the connection with the quadrants is made by means of screwed contacts. Further, for alternate-current work it is not only important to have as good contacts as possible, but also as little capacity as possible in the electrometer. This result we attain by removing the springy wire W, and electrically connecting the interior metallic coating of the glass shade with the exterior.

The next point to consider in designing this instrument was the size to give to the needle and quadrants. Theoretical reasoning, confirmed by some roughly made experiments, showed that the sensibility of the quadrant electrometer could be much increased if the needle and the quadrants were made smaller than in that instrument. We therefore made the

* Abstract of a Paper by Profs. W. E. Ayrton, J. Perry, and Dr. W. E. Sumpner, read before the Royal Society, June 4, 1891.

Digitized by Google

diameter of the quadrants, their vertical depth, and the length of the needle about six-tenths of the size adopted in the White pattern. Feeling, however, that the needle in the White pattern was not broad enough at the widest part to prevent its edges approaching too near the intersection of the quadrants when the needle was deflected, we thought it better not to reduce the width of our needle in the same proportion as its length. Therefore, while we reduced its length to six-tenths we left its breadth eight-tenths of the sizes adopted in the White electrometer.

Then as regards the controlling force. In our laboratories are electrometers with a bifilar suspension control, a torsional control, and a magnetic control respectively, and of these three forms we have found that the magnetic control is the best to be used in an electrometer, whose sensibility we require to be able to easily vary. The bifilar suspension control is unnecessarily troublesome, arising partly from the frequent necessity for adjusting for equal tension in the two fibres.

The magnetic control has no doubt the defect that the position of the needle is liable to be affected by outside magnetic disturbance. But this source of error can be practically annihilated if the magnet attached to the suspension wire be very short and be very weakly magnetised, and if the requisite magnetic couple be produced by the use of a very powerful controlling magnet placed near to the suspended system; and we venture to think that it was a neglect of this principle that caused the abandonment of the magnetic control originally employed by Sir William Thomson in his quadrant electrometers. Another plan that we have found very successful is to fix on the suspension wire an astatic combination of magnets, and to place the controlling magnet nearer one of the little magnets than the other.

But probably the most perfect plan is to use, as the astatic combination, two little vertical magnets, which may be conveniently attached to the back of the mirror, since such a combination remains necessarily astatic as far as rotation round a vertical axis is concerned, no matter how much one or both of the magnets may weaken with time.

Lastly, we supported the lower part of the guard-tube quite independently of the upper part, and hence the result is that, whether the quadrants be pushed far in, or pulled far out, this instrument obeys the recognised formula for a quadrant electrometer.

The brass rods R, R, which are each supported on a glass rod, carry all that portion of the apparatus that is at the potential of the needle, except, of course, the interior of the Leyden jar glass shade. The needle hangs by means of a silk fibre from a screw which can be raised or lowered by turning the nut N, a vertical slot in the screw and a horizontal pin projecting from the framework preventing the screw itself turning round. The platinum wire at the bottom of the needle dips into some sulphuric acid contained in a leaden cup L. This cup is supported and electrically connected to R, R by a stout wire X, the upper end of which slides through a clamping screw Y at the back of the lower end of the right-hand brass rod R. The leaden cup can, therefore, be easily raised or lowered and also centred. Similarly the lower portion of the guard tube is carried by a stout wire passing through a clamping screw at the back of the lower end of the left-hand brass rod R. After being put into position the tube is closed round the platinum wire, which projects down from the needle, but so as not, of course, to touch this wire.

The upper portion of the guard-tube is made in two halves, which are carried by the arms A, A attached to collars sliding with a bayonet-joint motion on the rods R, R. By raising up these collars and turning them round the two halves of the upper portion of the guard-tube can be opened, and the mirror and the wire attached to it got at. In fact, by opening and turning aside both the lower and the upper portions of the guard-tube, the mirror, needle and its attached wire can be left hanging freely from the silk fibre suspension, and it can be seen whether they are hanging properly or whether they require adjustment.

We have to thank Mr. Mather for taking a leading part in designing and constructing this improved quadrant electrometer.

HIGH-PRESSURE EXPERIMENTS.

The 130,000-volt 50 H.P. transformer, exhibited by Messrs. Swinburne and Co., at the Crystal Palace, was used on the 13th inst. at the first demonstration of a series of experiments which will add another attraction to the Exhibition. A considerable number of electrical engineers and representatives of the Press had been invited to a private view of this interesting "side-show." The transformer had been wound for 100 volts on the primary, with the intention of using it on an ordinary lighting circuit. As no suitable supply was provided by the management of the Exhibition, the Brush Electrical Engineering Corporation placed their large Mordey alternator at the service of Messrs. Swinburne and Co. for the purpose of these experiments. The voltage of the alternator being 2,000, step-down transformers of the ordinary Hedgehog type were used, giving 150 volts. A multiple-point resistance switch and a resistance composed of a pair of iron wires in an alkaline solution were used in the intermediate circuit. The transformer was enclosed in a large earthenware case, and within this, surrounded by oil, another case contained the transformer itself.

Some preliminary experiments were made with high frequency currents, by means of a condenser and an air blast. Vacuum tubes were suspended from a horizontal wire, and a few square inches of tinfoil hung below each tube served to increase the capacity. Although, as in Mr. Tesla's experiments, no return connection was made, the vacuum tubes glowed. The rest of the experiments were conducted solely by the current derived from the transformer, without any condensers or air blasts. Mr. Fox Bourne was in charge of the apparatus, and explained the effects. A sparking distance of 6in. between two pieces of fine wire was bridged by the high-pressure discharge, and it was possible, by allowing the engine to attain full speed, to start a discharge across even a greater interval. With polished copper hemispheres about 4in. in diameter, the sparking distance with the same voltage was reduced to less than 2in. When the discharge passed, the arc rose to the upper part of the hemispheres, which were placed at the same level, thus lengthening itself and rising up in an arched form, this being due probably to the mutual repulsion of the different parts and to the slight draught owing to the heating of the air. When two wires were brought within a few inches of each other, the arc in a similar manner tended to increase its length, running away from the place where it was started, and terminating at some angular projection of the wire. The heat at this point was sufficient to melt the wire in a few seconds, the extremity dropping off. As the wire burnt away the arc lengthened out into a long wriggling flame, which finally attained a length of between two and three feet. The flame appeared to have a thickness of about one inch, but was not brilliantly luminous. It is probable, however, that the apparent thickness was partly due to irradiation. This long ribbon-like flame assumed an arched form up till the last moment, when it could no longer span the continually widening gap between the burning wires.

A discharge was made to pass under some thick resin oil, and a little difficulty was experienced in preventing the formation of an arc across the wires above the surface, since the points beneath the oil had to be placed very close together compared with the distance between the leading-in wires. As soon as the discharge passed beneath the oil a loud spluttering gurgling noise was heard, and a small volcanic eruption with a yellow flame 2in. or 3in. high rose above the oil. This was repeated several times, and it was evident that when a considerable amount of power is used, amounting in this case to perhaps some 8 or 10 H.P., the oil has no self-healing properties. This absence of a property, which is well marked and extremely useful in cases of intermittent contact at low pressures, is no doubt due to the fact that with the rapid and continuously repeated discharges of an alternating-current dynamo, the viscous oil has no time to flow back upon itself, and the current is so large that a very material quantity of carbon is formed, which, together with the vapour of the oil, forms a good path for the current.

Digitized by Google

Several of the other experiments were similar to those which have already been described in our account of the recent meeting of the Old Students' Association (see *The Electrician*, March 18th, page 512). A piece of roofing slate permitted the passage of a continuous discharge from one corner to the other, the slate itself becoming hot, showing that an actual current had passed through its substance. A piece of dry pine, 2ft. long by about 2in. wide, and ¼in. thick, was subjected to 130,000 volts for some minutes, and sparks began to crawl out, partly on the surface and partly beneath it, from the copper wires bound round the ends. The path of the sparks was very irregular, and presented a branched appearance; the creeping discharges finally met, and the piece of wood burst into flame. An arc was formed, and at once rose, writhing and roaring in an arch over the flames. The brilliant effect produced by placing a sheet of glass between the terminals of a high-pressure alternating circuit was shown on a very large and beautiful scale, the glass being finally pierced. It was difficult, in these experiments, to utilise the whole of the 50 H.P., since all insulating substances broke down. At 130,000 volts it is possible to pass a small current through a man, and to transform it down and run a 2-H.P. motor. This experiment, however, was not performed. With a pressure of 130,000 volts this transformer could work a 50-H.P. motor placed in America through a wire a tenth of an inch diameter with a loss of only 2 H.P. on the way. The maximum current during these experiments was probably about one-half an ampere. The slate-pencil arc and the curious depression in the surface of the oil, and various other experiments, which have been already described in our columns, were very much appreciated by the large audience which had been invited to witness them.

A BURIED MICROPHONE.

BY ALEX. J. S. ADAMS.

A microphone was recently buried in the earth, in connection with the study of cosmical variations; and whilst the general result is for use in connection with that subject, the details of the experiment may warrant being separately told. It may be premised that the idea was to test whether a tidal movement of the earth's crust could be rendered manifest by the use of a microphone.

A shaft 4ft. square was driven to a depth of 16ft., through strata of subsoil, sandy clay, and sandy gravel. At the bottom of the shaft a hole was bored laterally for the packing away of the apparatus. The apparatus consisted of a single pencil of fine carbon, resting in cavities of fine carbon blocks. The wire connections were made by twisting tinned copper wire round the blocks, and clamping the whole together between two stout pieces of mahogany—this was fixed within a large glass jar. The gutta-percha connecting wires were passed through the cork stopper; the jar was heated to reduce and dry its atmosphere, and the cork then fixed in the neck with hot Chatterton's compound. The gutta-percha leading wires were served with warm tarred tape. The jar was dipped in warm tar, and all were then sanded. Within the jar was also placed a phial containing a record of the date and particulars. The jar was tightly packed into the lateral hole, a little over 16ft. below the surface; the leaders were brought up at one corner, and thence to the top of a high pole, from which they were extended through the window casing into the study. The gravel and soil were replaced and carefully punned, and it seemed that under the circumstances some sort of answer should be forthcoming from the arrangement. By means of a switch, the buried microphone was connected to a sensitive telephone, and one Leclanché cell.

During the quiet of many nights sound was intently listened for, and occasionally a faint grating was heard; but from the facts that it was chiefly after heavy rain, which caused a subsidence of the newly replaced earth, and that since the cessation of appreciable subsidence the sound has not been heard, it is believed the grating noise was due to settlement of the gravel. Beyond this, attentive listening never fails to discover a faint *breathing* in the circuit, as if fine sand particles—or, rather, dust particles—were constantly impinging upon the buried carbon: a sound without any variation, and which experiment amply proved to exist at the buried microphone.

The phenomenon suggested many things in explanation; but it was only by accident that the sound became understood. It happened that upon the accidental loosening of the spring contact of a switch, which was being used in an endeavour to reproduce the *breathing* in another microphone, that the sound became apparent, and, further, that by tightening or loosening the contact it could be produced at pleasure. It was evident that the bad switch-contact became virtually a microphone, and induced a self-effect. As a result this breathing can now be produced at will in either of the microphones in my possession.

The point seems of some importance, because whilst I am not aware that this microphonic self-effect has been previously noticed, the effect itself is a guarantee that the buried apparatus is sensitive, and that though the instrument remains undisturbed to the end of time, its breathing will be the evidence of its condition.

It is thus seen that the effects obtained are clearly explainable; and even if the apparatus be considered inadequate to the purposes of the test aimed at, the experiment *per se* is nevertheless of interest.

THE WORK OF JOSEPH HENRY.*

And now let us go over the ocean to Faraday, and see how he asks the great question. Bence Jones tells us that as far back as 1824 Faraday began the study of the subject. "He believed"—as did Henry—"with all his energy, that as voltaic electricity powerfully affects a magnet, so the magnet ought to exert a reaction upon the electric current;" and he makes an experiment which nearly makes the discovery. He again makes experiments in November, 1825, December, 1825, and April, 1828, but without result. "*The momentary existence of the phenomena escaped him.*" In the beginning of the year 1831 comes over the sea Henry's Paper in *Silliman's Journal*. It describes the magnets that have sprung up under Henry's hands and the rules of their construction. Faraday, with quick philosophic instinct, sees in these powerful instruments for producing magnetism means for a new trial of the old experiments, and again he goes to work. "He began his experiments on August 29, 1831." The essential apparatus, the means of the discovery used by the two men, like the discovery itself, is identical. Faraday saw his needle "oscillate," as Henry saw his "swerve," at the making and the breaking of the galvanic current. There is, however, a marked difference in the immediate mental attitude of the two men in regard to the observed phenomenon. Henry sees instantly that the question is answered. Faraday, on the other hand, does not seem to have understood the reply of Nature, or at least he seems far from confident of it. He writes to a friend the 23rd of September, "*I think that I have hold of a good thing; I cannot say. It may be a weed instead of a fish that after all my labour I may pull up.*" On the next day, September 24th, the third day of his experiments, he is again trying the effect of a helix of wire conveying the voltaic current of 10 pairs of plates upon another wire connected with a galvanometer, and other like experiments, but "*no induction sensible.*" Had Faraday at this time discovered the essential nature of the phenomenon, experiments like these could not have failed, in his hands, to give conclusive results. "He gave up experiments for that day with the electro-magnet and tried instead the effect of bar (permanent) magnets." An iron cylinder had a helix wound around it. The ends of the helix were placed between the poles of the magnet. Every time the magnetic contact was made or broken there was motion in the galvanometer. Now, but not until now, he reaches a positive

* Abstract of Articles IV. and V. of a series by Miss Mary A. Henry, appearing in the *Electrical Engineer* of New York. For abstracts of previous articles see *The Electrician*, January 29th, February 5th and 19th.

conclusion: "Hence here distinct *conversion of magnetism into electricity.*"

This constitutes his first distinct announciation of the phenomenon, so that his discovery can scarcely, in justice, be said to have been made until this day, September 24, 1831.

Not until the ninth day of experiment, October 17th, does he produce the deflection of the needle by thrusting a bar magnet into a helix of wire; the experiment which came over to Henry in that brief paragraph of April, 1832, and which incited him to repeat his own experiments in the last two weeks of June of the same year. With no other knowledge of Faraday's work than this particular mode of producing the effect, it is curious to see Henry in these June days bending the armature of his magnet into a ring; while, on the other hand, Faraday, equally unconscious of Henry's efforts, in his Paper of November, 1831, makes the important observation that "a soft iron bar, in the form of a lifter to a horseshoe magnet, when supplied with a coil of this wire, becomes, by juxtaposition with a magnet, a ready source of a brief but determinate current of electricity," thus adopting the precise method which had been employed by Henry.

Miss Henry then gives in full Bence Jones's account of Faraday's work up to September 24th, so that the reader may be enabled to judge for himself whether she has interpreted it correctly.

Then follows the experiment usually given in the text-books, as the one by which Faraday made the discovery:—

"'The fifth day of experiment was October 17th. Paragraph 57 describes the discovery of the production of electricity by the approximation of a magnet to a wire.

"'A cylindrical bar magnet, ⅞in. in diameter and 8½in. in length, had one end just inserted into the end of the helix cylinder (220ft. long); then it was quickly thrust in the whole length, and the *galvanometer* needle moved; then pulled out, and again the *needle moved*, but in the opposite direction. This effect was repeated every time the magnet was put in and out, and therefore a wave of electricity was so produced from *mere approximation of a magnet*; and not from its formation *in situ*.'

"The ninth day of his experiments was October 28th, and this time he made a copper disc turn around between the poles of the great horseshoe magnet of the Royal Society. The axis and the edge of the disc were connected with a galvanometer. The needle moved as the disc turned.' The next day, November 4th, he found 'that a copper wire, ⅞in., drawn between the poles and the conductors produced the effect.' . . .

"In ten days of experiment these splendid results were obtained. He collected the facts into the first series of *Experimental Researches in Electricity.* It was read November 24th at the Royal Society. Then he went to Brighton."

The great discovery of magneto-electricity is made. They were not conscious rivals, these two great men. Widely separated, each was simply intent upon finding out what nature had to teach. If one had failed to make this gift to the world the other would have done so. We desire to make no ungracious comparison between them, yet it is but just to consider the position which each held in reference to the discovery.

1. As to advantage of circumstance. Faraday, with nine years of advantage in age, has been at work in the Royal Institution of Great Britain for eighteen years, surrounded by every facility for study; with ample time at his command, and under the instruction of one of the most eminent men of the age. Henry, in what was then a frontier town of a new country, with no other aid than his own earnest purpose, has had to snatch his days of investigation out of busy years filled with other matters; his only apparatus rude tools made by his own hands.

2. Faraday has been at work upon the subject since 1824; has tried it again and again "without result," although the phenomenon, unperceived by him, has been actually produced under his hands. Henry succeeds in his first attempt.

3. As to the means of the discovery, Henry's magnet. He had sent it over to Faraday in *Silliman's Journal.* In making it he had made the stepping stone for both: had made it easy for Nature to answer the question. We might almost say the magnet made the discovery.

4. As to priority: And now we come to the chief object of our story. It has been hitherto supposed that Faraday could claim this; but is it so? Certainly, on the score of publication. His first series of brilliant experiments was given to the world in November, 1831, while Henry's Paper did not appear until July, 1832; but the world, advancing rapidly in every way, will soon no longer ask who was the first to *publish*, but who was the first to *do*. Which of these men was the first actually to make this discovery?

Let us attend first to Henry's spoken statements. Often by the fireside in his home he told to his wife and daughters the story of this great early disappointment; the story, in fact, as we have given it. How he made the discovery of the extra current five years before Faraday. How the discovery of magneto-electricity followed in 1830. How eager he was to pursue it, and how baffled by lack of time and materials. How he wished to amplify his results before he gave them to the world, and how he had commenced his great preparations for this purpose; and then, one day, in the library of the academy, seizing eagerly upon a newly-arrived periodical, how he suddenly came upon the notice which told him that although he had made the discovery so long before anyone else, Faraday must claim it. He might hurry his results into print, but Faraday was there before him. "He who publishes first claims the discovery" was a code strictly held by Henry; and so he laid down all claim to the discovery, and in the years which followed in Princeton always attributed it in his lectures to Faraday. An old friend (Rev. Theodore L. Cuyler, D.D.) one of Henry's earliest pupils in Princeton, said recently to one of his daughters, "Your father often spoke to me of his disappointment about that discovery. 'I ought to have published earlier,' he used to say. 'I ought to have published, but I had so little time. It was so hard to get things done. I desired to get out my results in good form, and how could I know that another on the other side of the Atlantic was busy with the same thing?'"

Let us now study the evidence which lies under our eyes, in the published statements, and the one or two letters we have collected in this article, and see whether they corroborate our story. Bence Jones says that Faraday commenced experimenting the 29th August, 1831, and that "the first experiment detailed in his note-book records the discovery." The experiment with the ring was made that day or the next; but the discovery, as we have shown, was not really made until the 24th of September, when he first recognised positively the distinct conversion of magnetism into electricity. However this may be, *the 29th of August is the utmost limit for earliness to be claimed for Faraday.*

And now let us look at Henry's Paper. We have given it entire, so that the reader may judge what it seems to say. It is published in July, 1832, but in its beginning it refers to last August, *that is August*, 1831, *the very August when Faraday is making his ring.* Henry says experiments were interrupted then, not to be resumed until "*the last few weeks*," which we find from the latter part of the Paper means "*the last two weeks* in June" (that is of 1832). A letter to Prof. Silliman gives us the cause of this interruption, namely, that the room used by Henry was required for the opening of the academy, and from another source we learn that the academy opened the 1st of September. So this is the first thing we learn, that Henry is busy with the subject at the same time that Faraday is, in August, 1831, and that between that time and the last two weeks in June there is an interval in which there are no experiments.

The second thing we learn from the Paper is that in this interval, "in the meantime," Henry says, comes a brief notice of Faraday's results dated April, 1832, and which Henry gives in the Paper.

Now look again into the Paper. It consists of a description of two series of experiments, *the one made before, the other after, seeing the notice of Faraday's result, dated April*, 1832. In the first series we find the great experiment. *If made before April*, 1832, *then before the close of August*, 1831, *the time when experiments stopped;* and into the very last of those August days must we bring the experiment in order to give Faraday priority, the utmost limit of earliness for Faraday being August 29th.

It is not likely that Henry was at work on the last day of August; he had to give up his room to be cleaned, to remove his apparatus. But if at work, what is he doing? Not making

Digitized by Google

this discovery—it has been already made. We are not left to conjecture; he tells us in his Paper with what he is busy in those August days, "*making a great magnet and other preparations for a series of experiments with it on a large scale, in reference to the production of electricity by magnetism.*" Henry does not say in his Paper when in August the magnet was commenced, but considerable time must have been consumed in its construction before the 29th came. He had to stand over the workmen while they forged that bar weighing 101lb. The insulating and winding of that reel of wire, a mile in length, alone represents an enormous amount of time, to say nothing of the winding of the magnet. Henry must have been at work from early in the month, on these preparations for his extensive series of experiments when that memorable August 29th came, and so we drive back the initial experiment *made before these preparations were begun*, to pursue the subject on a large scale. But it matters not for our present purpose whether this experiment was made days, weeks, or months before that August 29th, since it was before, to give Henry priority.

And so again is our point proved, since on the only day into which we must force Henry's experiment in order to give Faraday priority, Henry is distinctly busy *about something else.*

Does the Paper tell us anything else to throw light upon the date of the discovery? The magnet upon which it was made tells us something. Henry tells us in his Paper that the galvanic magnet used was the one described in *Silliman's Journal*, Vol. XIX.; the one he had made to sustain seven hundred pounds. The date of the Paper in which it is described is January 1, 1831, and the magnet was made in 1830. Thus is fixed for us the limit of earliness for Henry, that is, 1830. But there is something more in the use of this magnet. It suggests the probability that in this year 1830 the experiment we are in search of was made, because in January, 1831, was constructed the great magnet for New Haven, which remained in Henry's laboratory until spring came to break up the ice in the Hudson and allow it to be taken to its destination. With this more powerful, more complete magnet, in his possession, it is natural to suppose Henry would use this to ask the important question, rather than the earlier and inferior one, unless the experiment had been made before the construction of the larger one.

ELECTRIC LIGHTING OF BUOYS IN NEW YORK HARBOUR.*

Comparatively few people, other than those directly interested in the subject, have any idea of the difficulties experienced by vessels desirous of entering the harbour of New York, or of the magnitude of the works established and maintained by the Government for the safe guidance and protection of shipping interests in this, America's greatest port of entry. There are only two narrow channels through which vessels of average draught can pass, and only one which can be used by the larger ships, such as the transatlantic steamers. The entire bottom is covered by treacherous shoals and sandbars, and necessitating the use of no less than 80 buoys, 13 lighthouses, and two lightships to mark the dangerous localities and proper channels to be followed. The deep draught vessels are obliged to take the long and less direct route through Gedney's Channels, and it is here that a vast amount of time and money has been expended. Up to the fall of 1888, the entrance to Gedney's Channel was practically closed at night, having no distinguishing marks, except unlighted buoys. In 1888, however, in view of the great increase during recent years in the number, draught and speed of ocean steamers entering this port, together with the demands of commerce, the Government went into the matter very thoroughly, and a system of improvements was started which to-day, after an expenditure of over $2,000,000, has resulted in opening up a highway to the city 1,000ft. wide, with a depth of 30ft. at mean low water, through which vessels of the deepest draught can safely enter the harbour and proceed at once to their docks, at any hour of the day or night.

Owing to the constant changes in the course of the channel, from the action of the tides, it became a somewhat difficult problem to decide as to what was the best method of clearly defining its limits.

After much careful investigation and taking into consideration the peculiar requirements of the case, it was finally decided that a buoy in the form of a long spar, having its lower end securely shackled to an anchor or heavy sinker resting on the bottom, would be best adapted to withstand the effects of heavy seas and floating ice, and least liable to be displaced or broken by collisions with passing vessels. This being determined, the next important question was the manner in which the buoys were to be lighted, and here electricity came promptly to the front. It being clearly demonstrated that electric lights on the buoys would prove entirely satisfactory, so far as the brilliancy of the light itself was concerned, experiments were immediately instituted to give the best means of conveying the current from the shore to the buoys a practical test. The Bishop Gutta Percha Company, of New York, were consulted, an armoured cable was manufactured, and an experimental line was laid to a spar buoy near the Robbins Reef lighthouse, a distance of about 6,000ft. The buoy was fitted with an iron cage at the top, enclosing a heavy glass jar containing the lamp, and, after a variety of tests at different seasons and at varying states of the weather, a system was finally adopted suitable to the conditions prevailing in Gedney's Channel; and upon the approval of the Lighthouse Board, the necessary preparations for the erection of a permanent plant were promptly begun, and in November, 1888, the entire system was in operation. In consideration of the fact that the buoys in Gedney's Channel are, at the present time, the only ones in the world lighted by electricity, a few words in relation to the means adopted to accomplish this result may prove of interest. The channel marked by these buoys is 1,000ft. wide and about 6,000ft. long.

Two lines of heavy armoured three conductor cables, manufactured by the Bishop Company, are run to junction boxes, one on either side of the channel. Spliced to these main cables, inside the junction boxes, are three separate single conductor cables of lighter make, connecting the three buoys on either side of the channel, which are located about 2,000ft. apart, with the main line. One of these single conductor cables is spliced at the lower end of each buoy with the cable running up to the lamp, this wire being laid in a deep slot in the side of the buoy, and covered and protected by a strip of wood fitting closely over it and let in flush with the outer surface.

The buoys themselves are about 50ft. long, and are made of a species of juniper wood found in the dismal swamp of Virginia, this timber being selected on account of its buoyancy and straightness of growth. They average from 10in. to 12in. in diameter at the top and bottom, and 15½in. at the largest section, and are shackled at the bottom to a cast-iron sinker, weighing 4,500lb.

The protecting cage, in which the incandescent lamp is set, is composed of flat iron ribs, riveted to two iron bands encircling the spar, with a third ring at the top of the cage which serves as a handle (see Fig. 1). The upper part of the ribs and the top ring are turned so as to present the edge to the lamp, thus securing greater strength and obscuring the light as little as possible.

The lantern itself, which fits securely inside this cage, consists of a circular base and stout framework of brass, having curved panes of thick glass in the sides, and segmented panes at the top. It is so constructed that it can be lifted bodily out of the cage, thereby bringing away everything liable to need repair or other attention. Three short legs attached to the bottom ring fit into holes in brass ears riveted to the ribs, and the lantern is secured in place by two hinged screw clamps, which are also secured to the ribs.

The lamp is rated at 100 c.p., and the carbon is extra heavy and has three loops in the centre, designed to give a distribution of the light as uniform as possible. One terminal wire of the lamp is connected to the bars of the lantern, and the other is carried through an opening having an insulated bushing and connected with the core of the cable. One of the armour wires of the cable is soldered to a rib of the cage to insure a complete circuit through the core of the cable, the lamp and the lantern and frame to the cable armour.

The cables, originally laid, have given excellent service, and, considering the very hard usage to which they have been subjected, are still in first-class condition. The main difficulty that has been experienced is from mechanical, and, in many instances, malicious injury done to the cables, principally from vessels anchoring in or near the channel and getting the cables entangled in their anchors. In these cases the cable has been lifted from the bottom, and instead of being freed and allowed to drop back into position, has been deliberately chopped through and left for the lighthouse tender to pick up and splice together. There is no redress to be had for this kind of work, even if the guilty parties are known, as the Courts have decided against the cables and in favour of the vessels anchoring, which they continue to do, although warned against it by a large sign on Sandy Hook, which can be seen in the daytime and by a red segment set in the Hook beacon which covers the cable territory at night.

Since the service has been inaugurated the original heavy lantern has been changed for a lighter one, and straight glass has been substituted for the curved panes first used, so that they can be more readily replaced if broken. The lamp is also so adjusted as to

Digitized by Google

enable it to be taken out without removing the entire frame, if necessary, although the lantern can still be lifted out as formerly, if desired. The colour of the lights has also been changed, or rather they have been differently located, those on the starboard side of the incoming vessels being now all red and those on the port side all white, instead of alternating, as they were originally.

As an instance of the hard usage to which the buoys and lamps are sometimes subjected, and the excellence of the service rendered under those conditions, it is only necessary to mention that during the severe storm of January last the ice surrounding the lamps was as thick as a good sized barrel, and the weight of this ice, combined with the heavy sea, was sufficient to keep the buoys for the greater part of the time completely under water, In spite of this, and regardless of the mass of ice surrounding them, the lamps continued to burn brightly and without injury, and, as often as they could manage to get their heads above water, were plainly visible from the shore of Sandy Hook, a distance of nearly three miles.

The three years' practical demonstration of the feasibility of this system of lighting, and in view of the excellent results attained therefrom, the only drawback being, as before stated, from mechanical injury to the cable itself, it was decided, a short time ago, that in order to insure the best results in the future it would be advisable to substitute a still heavier armoured cable than the one now in operation, at least at the channel end of the line, where it was most liable to injury. Accordingly, the Bishop Company received an order for about 18,000 feet of new cable which would fill these requirements, and have turned out an article which, it is hoped, will prove durable enough to warrant its adoption throughout the entire system of coast lighting.

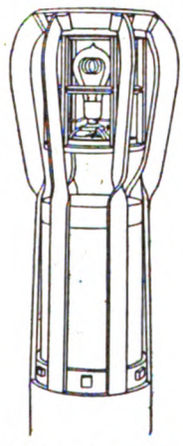

FIG. 1.—Protecting Cage for Incandescent Lamp at head of Spar Buoy.

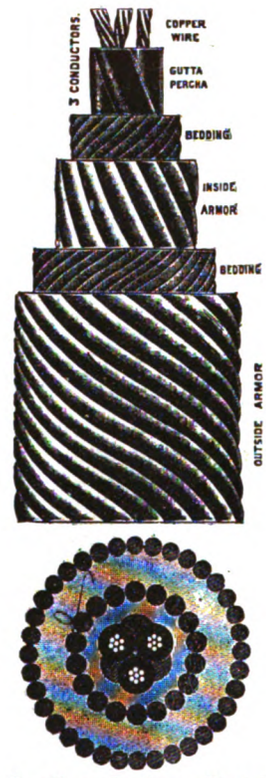

FIG. 2.—Three-Conductor Electric Light Cable, used in connection with the Buoys in Gedney's Channel, New York Harbour

The new cable (Fig. 2) a longitudinal and cross section of which is here shown, is similar to the first one, in so far as the conductor wires and insulation is concerned, this part having proved entirely satisfactory. Over the first or inner armour is a bedding of strong tarred hemp saturated with a bituminous compound, designed to keep the zinc of the galvanised wire intact, and so prevent rusting. This again is covered by a second iron armour, which is wound on with a "short lay," in order to reduce as far as possible its tendency to kink when dragged from position by the tide, anchors or other causes. When finished the whole cable is treated to a bath of hot bitumen, and is then ready for laying.

The tide eddies, combined with the heavy swell prevailing off Sandy Hook, furnish a large element of difficulty to be overcome in making repairs to the cables when necessary. This work is generally done from one of the lighthouse tenders, except in heavy weather, when it is customary to use a large cargo boat, as it can be handled more readily and with less danger of breaking the cables. When first laid, and for some time thereafter, the splices were made by the *employés* of the Bishop Company; but latterly the men at the station, who from the first have shown great interest in the work, have become so proficient that they are able to handle all the necessary repairs themselves; and this has proved a great advantage, not only in the matter of time and expense, but also from the fact that oftentimes they have been called upon to repair a break in bad weather, and have been able to do the work while tossing on a sea that would compel the average landsman to "give it up," together with whatever else he had with him. The matter of raising a cable successfully in order to make a splice is by no means an easy matter, as they are frequently found to be covered with from 6ft. to 8ft. of sand, causing a very severe strain in raising, and requiring great care to avoid breaking. It generally takes about three hours to splice one of the single conductor and four hours for one of the triple conductor cables.

The power station on Sandy Hook, from which the current is supplied for the buoys, is a model of efficiency, and no trouble of any kind has been experienced here since the plant has been in operation. Every part of its equipment is of the best, and no effort has been spared to insure the best results. All the working parts are in duplicate, and the failure of the lights through any accident to the steam or electric plant is simply out of the question. The station itself is a compact and substantial brick building, two stories in height, with a one-story brick extension containing the boilers. These, of which there are two, are of the upright tubular type. The average pressure of steam carried is 84lb. with a daily consumption of 680lb. of coal. The engines are of the Armington and Sims horizontal automatic type. They are of about 7 H.P., the cylinders are 6in. in diameter with a 7in. stroke, and are run at 380 revolutions per minute. The entire electrical outfit was furnished by the Edison Manufacturing Company, of New York. The dynamos are continuous current compound wound machines making 1,720 revolutions per minute, and generating a current of 25·5 amperes, with an E.M.F. at terminals of 160 volts. The wires are supported on a line of substantial poles to the beach, a distance of about 1,500ft., where they are connected to the cables. The cost of the entire plant, including a naphtha steam launch built purposely for attending the buoys, was $19,530, and the average operating expenses per month are about $400.

The average efficiency of the entire system, taking the total number of lights for every night of their first two years of service, and deducting therefrom the time any of them were out of order, from whatever cause, leaves the percentage of perfect service rendered 93·61, which, on the whole, is a most excellent record. Now that the officers and men at the station have acquired their experience in working the cables and buoys, and the fact that a heavier cable has been laid, which will be less liable to damage, the record for the next two years should be even better than that already shown, and it seems reasonable to infer that the excellent results already obtained will eventually lead to the general adoption of this system of lighting throughout the service.

THE DANGERS OF BARE COPPER UNDERGROUND MAINS.*

BY J. A. MONTPELLIER.

The employment of bare copper conductors laid in underground troughs may under certain conditions give rise to accidents, which it is worth while to point out. This system, as is generally known, has been used in Paris in the districts allotted to the Compagnie Continentale Edison, the Compagnie Parisienne d'Air Comprimé et d'Électricité, and the Société d'Éclairage et de Force par l'Electricité.

With perfectly watertight concrete troughs, fairly good results have been obtained, in spite of the inevitable current leakage. The conductors, however, are soon covered with a layer of carbonate of copper, which in some cases becomes thick enough to appreciably diminish the cross-sectional area of the conductor, and render it consequently of far higher resistance. Owing to this fact the conductors become more heated by the current; and the rise of temperature, added to the damp which prevails in the troughs, stimulates the production of carbonate of copper. A time must, therefore, sooner or later arrive when the conductors will be so corroded as to be no longer utilisable. We can, it is true, in a certain measure, impede the production of carbonate of copper by covering the conductors with a bituminous compound analogous to that used to protect the iron sheathing of submarine cables; but we should then be using a kind of insulated conductor, and consequently abandoning the system of bare conductors. Without making a definite pronouncement as to the

* From *L'Electricien.*

Digitized by Google

efficacy of this process, it is almost certain that the use of this bituminous composition would remedy most of the defects pointed out—that is to say, it would reduce the current leakage to more reasonable proportions, and it would prevent the destruction of the copper.

When the conduits are not perfectly watertight far more serious accidents than those alluded to may occur, a striking proof of which was the explosion which recently took place in a manhole in the Rue Taitbout, belonging to the Edison Company. In certain narrow streets the Edison Company, seeing the impossibility of running the concrete conduits usually employed, adopted rectangular stoneware troughs. It was this type of conduit which was laid down in the Rue Taitbout, where the accident took place. The result of this explosion was to project a cast-iron manhole lid to the height of a first story, fortunately without any other consequence than injury to material. The cause of the explosion can evidently only be attributed to the firing of explosive gaseous mixtures. What are these gases, and under what conditions are they formed? In the case under consideration, illuminating gas being deemed out of the question, since no gas escape was detected in the vicinity of the electric mains, the explosive mixture must have been composed either of oxygen and hydrogen (due to the electrolysis of water) or of hydrogen and chlorine (the elements of hydrochloric acid), or perhaps of these two mixtures produced simultaneously.

The production of oxygen and hydrogen is explained quite naturally by the electrolysis of the water which percolated into the conduit. But if this reaction was a cause of the explosion, it was not the only one, since the production of the hydrogen-chlorine compound was, as we shall see, the principal cause. In fact, appreciable quantities of carbonate of soda, mixed with carbonate of potash and caustic soda, were found in the conduit. The copper conductors were much eaten away, and the layers of copper salts which surrounded the conductors were formed, not only of verdigris, but chiefly of chloride of copper. The presence of these perfectly definite saline bodies within the conduit showed that we had to do with complex electrolytic phenomena. How are the relatively large quantities of carbonate of soda and caustic soda to be explained? The only plausible explanation seems to be the following. When snow falls in Paris, a large quantity of impure chloride of sodium is thrown on the roads. The water which runs into the gutters consequently contains appreciable quantities of this salt; and it is not astonishing, therefore, that the water percolating into the conduits should be the prime cause of the phenomena observed. Under the action of the current, the chloride of sodium in solution is split up into its elements, the chlorine going to the positive and the sodium to the negative pole. The sodium immediately decomposes the water, taking up oxygen and forming soda, hydrogen being evolved. Hence, by electrolytic action, chlorine is evolved at the positive pole, and hydrogen at the negative (with formation of soda). Now, as is well known, a mixture of hydrogen and chlorine forms an explosive compound, an explosive combination of the two gases being instantly produced by an electric spark or by contact with a flame. In the present case the combination of the sodium with the oxygen of the water may well have caused so great a rise of temperature that, under certain conditions, the freed hydrogen may have been set on fire and have fired the explosive mixture.

In this way not only may be explained the explosion itself, but also the presence of carbonate of soda. In fact, the caustic soda combines very rapidly with the carbonic acid of the air, and the superficial layers thus transformed into carbonate surround the caustic soda, which, being thus protected against the air, carbonates more slowly. As to the presence of carbonate of potash, that is due to the transformation of the potassium chloride, which is always to be found in the impure chloride of sodium used to melt snow.

We therefore see that bare copper systems of underground mains may give rise to accidents; and daily experience shows that it is necessary to employ conductors which if not completely insulated are at any rate protected by an insulating varnish. The Edison Company has indeed grasped this fact, and is now carrying out the complete reconstruction of those parts of its network where stoneware conduits were originally laid down; it also proposes to cover the conductors with a protective varnish.

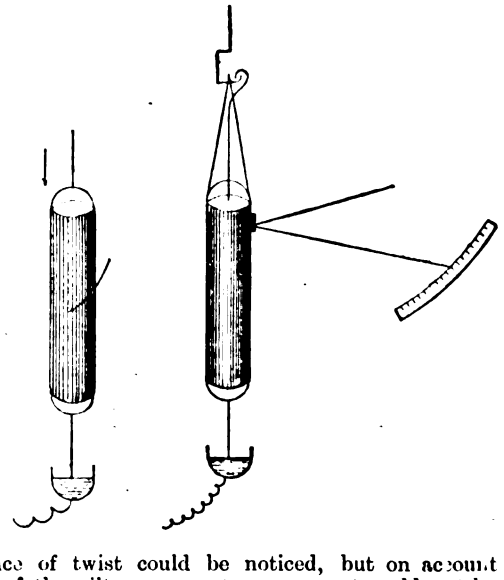
Electric Launches.—The electric launch constructed by Messrs. Woodhouse and Rawson United at their Chiswick Works to the order of the Southport Corporation, for use on their artificial lake was running during the Easter holidays with remarkable success. This boat, which will seat 40 persons, is 38ft. 5in. long, has 7ft. 6in. beam, and draws about 2ft. 3in. of water. She is propelled by a 5 H.P. "W. and R." motor.

NOTE ON THE MOLECULAR MOVEMENT IN A CONDUCTOR.*

BY PROF. A. E. DOLBEAR.

Maxwell and others have made experiments to discover whether there was any evidence of momentum in a conductor carrying an electric current. So far as I know, all the experimenters looked for a *longitudinal* momentum, that is, one in the direction of the current in the conductor, but no evidence appears to have been discovered that the molecules are thus moved. Still it is as nearly certain as anything can be and not be demonstrated, that the molecules in a conductor are moved in some way by an electric current. If they be thus moved then there must be momentum in some direction. If it be not longitudinal it may be transverse. If there should be movement in the transverse direction, what kind of experiments would be needed to show it? This is the way the question presented itself to me. When a current is sent through an *iron* wire the latter is twisted to the right or the left according to the direction of the current. This is interpreted as due to the specific magnetic quality of the conductor, for it does not occur in a copper or other conductor.

Suppose the molecules of a conductor to be *rotated*, each upon its own axis, the axis being longitudinal with the wire, what evidence of such motion would be externally exhibited by the conductor as a whole? Evidently it would be masked altogether in a common wire, for the momentum of any one molecule in one direction would be just balanced by that of the contiguous one in the opposite direction—a condition of things mechanically propagated through the diameter of the wire. In order to discover it, it would be necessary to prevent such mechanical transference of the movement, and this can be done by making the conductor a hollow cylinder. I therefore made a cylinder of gilt paper about 20in. long and 4in. in diameter, this I provided at each end with a bail for suspension, thus, the suspending wire being 8ft. or 10ft. long, the lower end of a short wire dipping into a mercury cup as shown (*ce figure*). With this arrangement



a decided evidence of twist could be noticed, but on account of the resistance of the gilt paper, a strong current could not be used without so high a voltage that the paper took fire several times. I then had a thin copper cylinder made of nearly the same dimensions and suspended in a similar manner, and could use a current of thirty or forty amperes. The rotary motions were in the same directions as before, namely, when the current was going down, the twist was always right-handed as indicated by the arrow, and of course opposite when the current was reversed. While there was no doubt about the rotary movement, the weight of the apparatus was so great, I concluded to see if one made of lighter material—aluminium—would not give greater amplitude with the same current. A similar cylinder of aluminium foil was prepared and so hung that all tangential movement would be due solely to itself, and not at all to any other part of the apparatus, that is, it was mounted with bifilar suspension. The weight of the foil with its connections was 1·85oz. 55·6grams. A bit of mirror was fastened to the upper end, and a beam of sunlight reflected from it upon a scale 16ft. distant and 25ft. long. With this arrangement the twist produced by the current was such that it was not difficult, by timing the swings and changing the direction of the current, to make the cylinder swing through

* Abstract, from the *Electrical World* of New York, of a Paper read before the American Institute of Electrical Engineers.

Digitized by Google

90deg. A current of 15 amperes swung it through a foot and a half on the scale. It would come to rest at about half the distance of the greatest amplitude of the swing for each different current employed, and *therefore showed the continuous action of the torsional force for a constant current.* If this be the interpretation of the phenomenon, then the molecules are rotating when there is a constant current, and thus the explanation of the heating effect of the current is brought back to dynamical and mechanical principles. Adjacent molecules must be rotating in opposite directions at their point of contact, but this vibrating or heat motion necessitates more or less separation when such rotation goes on; on impact, it is arrested, so there must be impact and slip, the arrest of motion being the immediate antecedent of the heat, as is friction in any case. These experiments have not been carried out quantitatively for lack of facilities. May be the interpretation is wrong, and some wise one who knows all about it can point out its inadequacy. I think the experiments are new, and may lead to an understanding of what goes on in a conductor when a current of electricity traverses it, if this be not the whole of it.

In the discussion which followed the reading of this Paper, Mr. Mailloux said that he thought the horizontal component of the earth's magnetism might have a great deal to do with the rotation. A wire or a cylinder situated as this is in the earth's field would have present in it Hall's phenomenon, that is to say, the current would not be distributed equally throughout the mass of that cylinder. He thought that this might be a partial explanation of the observed rotation.

Mr. Wolcott did not think that the earth's field would cause continuous rotation if the tube were perfectly straight and perfectly uniform in resistance.

Dr. Pupin called attention to an experiment made some years ago by Prof. Braun. He found that a wire made of a magnetisable substance when twisted one way would generate an E.M.F. in one direction, and if twisted the opposite way it will produce an E.M.F. in the opposite direction.

Mr. Binney suggested that the cause of rotation may be due to the fact that there was more current in one of the bails than in the other, owing to the tendency to lateral shifting in the magnetic field.

Prof. Crocker suspected a lack of symmetry, stating that if the cylinder were a little thicker on one side than on the other, the current would be stronger on that side. If it were perfectly symmetrical he claims that according to our present knowledge of electrical currents there would be no tendency to rotate.

Mr. Carl Hering suggested that interesting results might be obtained if the conducting cylinder were surrounded by a fixed iron cylinder. This would shield it from the earth's field, and if the motion were due to the magnetic lines circulating around that conductor the effect would be increased because the iron cylinder increases these lines.

MEASUREMENTS OF THE HYSTERETIC LOSS OF MAGNETIC ENERGY IN NICKEL.*

BY A. E. KENNELLY.

The energy absorbed in hysteresis by substances under reversals of magnetisation is probably measured most conveniently by the use of a wattmeter with an alternating current. This method cannot be employed when the Ewing H B diagram, or the relation of flux to field, is required, but where only the integrated area of that diagram or the hysteretic energy per cycle is needed for definitely varying maximum flux densities, the convenience, swiftness, and precision with which the observations can be carried out give it great advantages.

Measurement was made of the hysteretic loss of energy in two samples of good commercial nickel wire, each wound up in a coil or Faraday ring. The connections are shown in the Fig. 1. P and S are the primary and secondary coils of a transformer operated by an alternator with an average and nearly uniform frequency of 141·6 ∿. The regulation of the alternator fields controlled the E.M.F. in the coil S, whose circuit was closed through the ammeter A, the fixed coil of a dynamometer wattmeter D, and the insulated winding of the nickel wire ring R. The suspended coil *c* of the dynamometer was permanently connected through an adjustable resistance *r* across the terminals 1 and 2 of this ring. Before and after each wattmeter observation the Weston alternating-current voltmeter V was also connected to the terminals 1 and 2, and a reading of the pressure taken.

The dynamometer was a nearly dead-beat, unifilar torsion instrument, read off by telescope, mirror and scale. Its suspended coil having eight ohms and three millihenrys, in circuit with the resistance *r* of from 1,000 to 6,000 ohms according to the pressure, it is evident that the error in the readings due to lag in the suspension circuit was negligible. The instrument was also sensitive, and gave about 20deg. of twist per watt of indicated power.

It is worthy of remark that the use of such alternating current wattmeters has been often avoided on the ground of inductance error, but when made with sufficient sensitiveness to need only small inductance with high resistance in the suspension circuit, the charge is unfounded, and their indications in power measurements become reliable. For if *c* be the current passing through the fixed

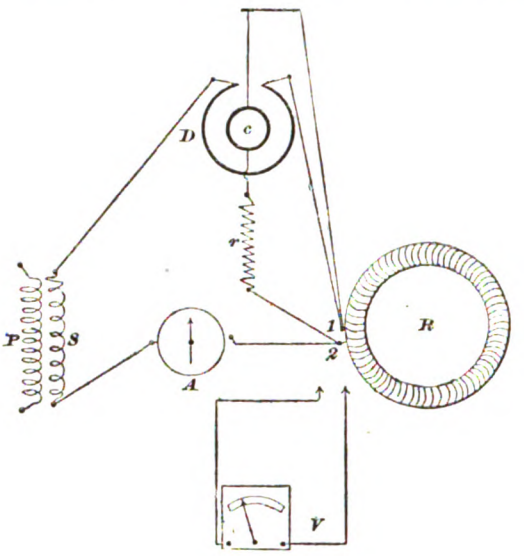


FIG. 1.

coil, and *s* that in the suspension, under an effective pressure *e* through a large resistance, *r*, with a total inductance, *l*, the maximum error in watts that *l* can effect in the readings with a pulsation, $p = 2\pi n$ is,

$$r\,s\,c \sin \tan^{-1} pl/r, \ldots \text{ or very nearly } \ldots e\,c\,pl/r.$$

In other words, the maximum error would be the apparent watts or product of volts and amperes multiplied by pl/r, while the actual error is generally much below this limit.

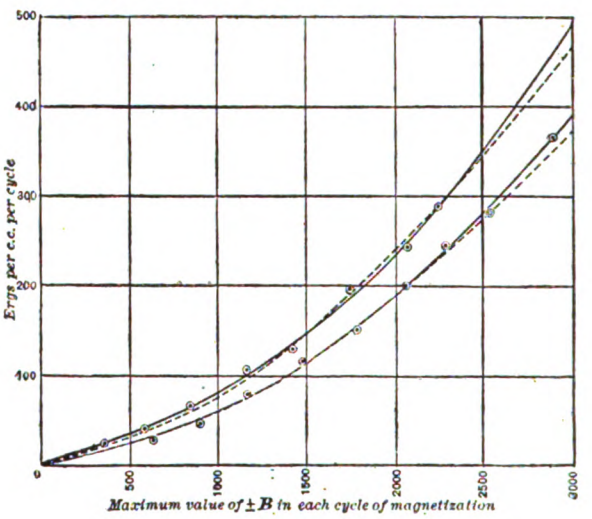

FIG. 2.

The particulars of the rings are given in the following table. The weight of nickel in each was the same, but the diameters of the nickel wires were different. The winding of insulated copper wire was also the same on each :—

Coarse Wire Ring.	*Fine Wire Ring.*
Turns of wire 570	between 4,000 and 5,000
Diameter of wire ..... 0·0365″ 0·0927 cm.	0·0126″ 0·032 cm.
Sectional area of wire ..... 0·006749 sq. cm.	0·000804 sq. cm
Weight of wire in ring ..... 2,255 gms.	2,255 gms.
Volume of wire in ring ..... 253·3 c.c.	253·3 c.c.
Cross-Section of Ring.	
By number of wires..... 3·848 sq. cm.	
By external dimensions ..... 3·852 „	3·852
Mean diameter of ring ..... 20·93 „	20·93 cm.

Winding ..... 700 turns of copper wire on each ring.
Resistance of winding at 18° C. ..... 2·815 ohms.

* From the *Electrical Engineer* of New York.

Digitized by Google

Before applying the copper wire winding to these rings, they were well soaked in melted paraffin wax, with the object of limiting all eddy currents as much as possible, although previous tests on the rings without this precaution do not by comparison show appreciable loss from eddies when the bare nickel wire was used. Some 200 grammes of paraffin wax was absorbed into the rings.

In reducing the measurements, the wattmeter readings were corrected for the extra incidental losses of power, namely, e^2/r in the suspension circuit, and c^2 R in the ring. The balance gave the loss in hysteresis assuming no loss in eddies. The voltmeter pressures at ring terminals reduced by c R gave the counter E.M.F. of the ring, from which the maximum flux density in the nickel was determined on the assumption of a simple harmonic E.M.F.

The accompanying curves (Fig. 2) show the resulting ranges of hysteretic loss per c.c. of nickel for the two rings at varying flux densities. The loss is nearly 25 per cent. greater in the coarse wire. The curves agree very fairly, however, with the law of $\frac{5}{3}$ exponent, as lately enunciated by Mr. Steinmetz* for iron, the dotted lines representing the locus of this exponent drawn from the datum point for $B = 1{,}500$ on each curve. The hysteretic loss in ergs per c. c. per cycle for the coarse wire is thus apparently $0{\cdot}00125\ B^{\frac{5}{3}}$ for the coarse wire, and $0{\cdot}00101\ B$ for the fine, between the limits of 0 and 3,000 of maximum cyclic flux density.

There are two reasons for believing that this difference between the absolute values of the hysteretic loss in the two rings was not due to eddy current influence: 1st, that, as above mentioned, the loss of energy was not found to increase when no paraffin was used to insulate the wires; and 2nd, that eddy current influence would introduce a term varying as B^2, and the resulting curve would diverge from a curve of $B^{\frac{5}{3}}$.

The hysteresis was quite definite in each ring, and any reading could be reproduced at will, by adjusting to the right pressure at the voltmeter. Eight series of measurements were made in this way at different times, four series on each ring. The results seem to show that, approximately at least, the hysteresis in nickel varies, as in iron, with the $\frac{5}{3}$ power of the maximum flux density, although the difference in the coefficient would indicate some latitude in the amount of hysteretic dissipation with different specimens. As with iron, therefore, doubling the flux density in nickel practically trebles the hysteretic loss.

The writer is indebted to Mr. A. Hoopes for assistance in carrying out this measurement at Mr. Thomas A. Edison's laboratory.

THE TELEPHONE AT HOME AND IN THE FIELD.†

BY MAJOR C. F. C. BERESFORD, R.E.

After a brief glance at the history of the telephone the author proceeded to describe some of the instruments and appurtenances at present available in the military service. The "Ader" receiver, he said, could be used without a microphone, on short lines, as a speaking instrument, but was only of very moderate power when so used. Its great value, however, appeared when in combination with the instrument familiarly known as the "vibrating sounder," or "buzzer," a system introduced some years ago by Major Cardew, which enabled communication to be held under circumstances when every other form of telegraph would fail. The "buzzer" might be called the backbone of British field telegraphy. When a microphone was added, the combination could then be used at will for speaking, or for communication by Morse signals. The "Ader" apparatus complete, *i.e.*, telephone and microphone, was one of the best at present existing for speaking purposes. It had given excellent results during the last year at Aldershot for work between the various temporary camps, on the new Ash ranges, and on the "Exchange" systems during the manœuvres. It was not so portable as the "Operators" telephone, but spoke louder. The "Berthon" microphone was of a very portable form, useful for telephones in forts where the firing of heavy guns was apt to break the carbon pencils in the other pattern of microphones. The "Operators" telephone was a combination of the "Berthon" microphone and the "Ader" receiver, the two being fixed to one handle. The "Siemens-Halske" pattern had been used a good deal in foreign armies. The "Aubry" telephone, from experiments at Aldershot, appeared to give as good, if not better results than the "Ader" receiver. It was the pattern used in the French army. The "reed" form of call, being the simplest, would seem to be that most suitable for the future development of telephones for outpost work.

It might appear, at first sight, that, in matter of pace, a telephone used for speaking had great advantage over one used for Morse signals, or over a telegraph instrument. But practically for written messages the pace was limited to the writing pace of the receiving clerk. Although the human voice could send a message at the rate of from 150 to 200 words per minute, and although this might possibly be received on a good telephone, it could not be written down except by shorthand. From practical experience at Aldershot, when in some of the Divisional Offices both telegraph and telephone were working side by side, there was no doubt of the great superiority of the sounder over the telephone circuits for carrying traffic. On the other hand, the telephone circuits required little or no special qualifications for the clerks employed, while, for the military sounder clerks, picked men and a training of from four to six or nine months were necessary even for second-class officers. A way of increasing the carrying power of ordinary telegraph lines would be—(1) Improved telephones; (2) a more wide-spread instruction in shorthand writing. The telephone, as a speaking instrument, in its present state, was rather more suited for conversation than for the transmission of important military orders, at any rate in the field. For use on the main line of communication, or for outpost duty, except under exceptional circumstances, the effective use of the telephone for speaking was doubtful.

Attention might be next directed to the consideration of circumstances under which the telephone can be profitably employed for army purposes.

These might be generalised under the following headings:—

(1.) Telephones and exchanges in garrisons.
(2.) For coast defence, including artillery, submarine mining, and general purposes.
(3.) On rifle ranges.
(4.) On artillery ranges.
(5.) For siege operations.
(6.) Main lines of communication in the field.
(7.) Intercommunication in camps.
(8.) Outpost duties.

For garrison work the use of the telephone was obvious; it was employed at all our garrisons and dockyards at the present moment, and its great extension was merely a matter of time. As to the telephone for coast defence, he had no personal experience. During the spring of 1891 telephone lines were erected along the three new rifle ranges at Ash, near Aldershot; the instruments used up to the present time were "Aders"; these had given such good results that the extension of the system to all ranges might be confidently looked for. Colonel Lyons, the Commandant at Lydd, had made a series of valuable experiments with various forms of telephones for use in directing artillery fire at siege operations, and for observing and plotting results. He had come to the conclusion that the telephone as a talking instrument was not reliable for this purpose, but when used in combination with the vibrating sounder it did excellent work.

For work on main lines of communication the telephone, as a talking instrument, would not be of much service. In the first place, it would not carry the traffic which we were accustomed to, and, to give it fair play, it should be served by a well-insulated line, with double wires if on the same poles as other lines. These conditions were frequently impossible on long field lines. At the same time, occasions would often arise when it might be desirable for commanders in the field to hold direct communication by telephone, and arrangements for accomplishing this at will should always be made. The Belgian system, introduced by Major Waffelaert, admitted of a telephone and telegraph instrument being used simultaneously on the same circuit, without interfering with each other. We had in the British army an appliance known as a "separator," which accomplished the same purpose; but it had not, as yet, come into general use, although it had a promising future before it.

As an example of what the telephone might be expected to do on a long field line, he might mention the experiments carried out during the summer exercise of the 1st Division Telegraph Battalion last year. A field line 70 miles in length was run between Aldershot and Chatham, and on many occasions was used for telephone work. The line, running as it did through woods and narrow lanes where contacts with trees and hedge-rows were unavoidable, was a very leaky one, but did not prevent the telephonic communication being carried on with fair success. The instruments used were the "Ader" and the "Operators" telephone, and on the occasion of a ball which took place at Chatham animated conversation was kept up between the guests and some officers at Aldershot. The "Ader" appeared to give the best results.

The first military telephone exchange was established in Portsmouth garrison, over ten years ago. That at Aldershot was not established until within the last five or six years, but was now crowded with work. Plymouth followed suit some three years back, and the Curragh is meditating on the subject. The naval dockyards had all, long since, had telephone exchanges. The appliances of modern civilisation were of slow growth in the British army, but they came in the end.

During the summer manœuvres of last September, in Hampshire, exchanges were established in the camps of the two divisions, being

* "On the Law of Hysteresis," a Paper by Mr. C. P. Steinmetz, read before the American Institute of Electrical Engineers, Jan, 19, 1892. See *The Electrician*, February 12th, *et seq.*

† Abstract of a Paper read before the Royal United Service Institution.

Digitized by Google

the first instance, it is believed, of anything of the kind having been tried in the field. The exchanges were in constant work during the manœuvres, and the valuable results obtained might be judged of by the favourable opinions expressed by commanding officers. The consensus of opinion left little doubt of the efficacy of a telephone exchange for camp work, or of the probable demand there would be in the future, and, considering the simplicity of the apparatus needful, there would appear to be no great obstacle to its adoption universally. The question reduced itself to that of the men available for the erection and maintenance of such exchange systems. On home service, the telegraph battalion could often manage to provide them ; but on active service, when the whole of the energies of this body would be devoted to the lines of communication, telephone exchanges might go to the wall. It then remained to be considered whether the advantages to be gained would warrant the necessary equipment being carried and maintained by regiments.

Taking it for granted that the R.E. could provide the exchange switch, which would be erected alongside the telegraph office, the following equipment would be necessary for each regiment :—

1 telephone complete, with microphone transmitter.

1 magneto call.

1 small battery.

Half a mile of cable on a drum, weighing about 50lb.

A few small stores.

Thus equipped, a regiment would, as soon as its camp was pitched, lay its own cable up to the exchange office, where it would be attached to the switch by the telegraph battalion. The original outlay for such an equipment would be about £20, with an annual expenditure of, perhaps, £5 ; and even if this was doubled, the total amount would bear favourable comparison with the cost of one soldier, while it would probably set free the services of several. The carriage of the stores would be trifling ; there would not be more than what two men could carry with ease, the cable being on drums similar to those in use by foreign armies.

Under the head of outpost telegraphs there might be also included all light telegraph work in advance of an army. Whether in repair and utilisation of the lines of the country, temporary lines for local purposes, lines in connection with reconnaissances, or arrangements for tapping the enemy's wires. During the American war the telegraph went ahead of all troops, with or without escort, generally the latter. During the Franco-German War the telegraph work was frequently pushed ahead beyond the cavalry screen, and specially escorted for the purpose ; such was the necessity in warfare of at once gaining communication to the front. Continental Powers were equipping their cavalry with the telephone and telegraph, but it was to the former that the greatest attention was being given. It might now appear to us time to inquire whether we should not be moving in the same direction.

We were not now uncertain of our field lines, as we were in years gone by, when our equipment was of inferior material. There was now a cable in our service, weighing 70lb. per mile, that would stand a strain of 500lb., that had frequently been passed over by artillery and remained intact. In the vibrating sounder we possessed an instrument which in combination with a telephone would transmit signals through bare wires laid on the ground, and even in water. It rested, then, with those in command to say whether such means of communication as had been described would be useful on outpost duties. Whether occasions would not arise when to be able to speak between main body, reserve, and picquets might not be of infinite value. Whether the establishment of some detached post might not entirely depend on the facility of communicating with it. Whether the fact of being able to communicate immediately with the chief points of an outpost line would not reduce the number of men necessary for outpost duty. Whether the knowledge that communication was open throughout would not give confidence to the soldier. And finally whether the mere fact of lines of cable, radiating from certain centres, would not be of great use, especially at night, as providing guides for reinforcements and the like.

Then as regards the cavalry : should they not be in a position to tap an enemy's line (which could be done with the telephone), or to complete and work a deserted circuit, when the local instruments would probably have been taken away ? Or to run short lines for connecting their headquarters with certain points, or with the head of the advancing main line of communication ?

It was as a Morse receiver that the author looked for the best results from the telephone. But this would require trained clerks. Any intelligent man, with a good ear, could in a few months be taught to read sufficiently well for most practical purposes connected with military local work. Many become fair operators in six months. Most regimental signallers who passed through the Signalling School at Aldershot acquired there a fair knowledge of reading by sound, and it would be to those to whom the charge of regimental telephones would naturally fall.

In France the question of outpost telegraphs had been well to the front for some years. France had taken the lead from the time that she saw what the telegraph effected in the war of 1866, and ever since that period she had striven to get the most out of the products of science.

Germany had had for some years the Buchholz-Siemens system for outpost telegraphs. A combined telephone and microphone similar to that introduced into our service had lately been adopted. There was a strong prejudice in Germany against the use of the telephone, on account of its not recording the messages.

In Belgium Major Waffelaert, the Officer Commanding the Telegraph Corps, was a strong advocate of telegraphs for outpost work, and had devoted much time and thought to the subject. The system he had adopted for the Army telegraphs was that known as "Rysselberghe's," whereby it was possible to use, at will, the telephone and telegraph instrument, simultaneously or otherwise, on the same circuit. Major Waffelaert considered that Morse signals were not adapted for outpost work, on account of the difficulty of obtaining trained clerks.

Italy had been disposed to use telephones for military work more than any other country. She was the first to make use of the vibrating armature for giving signals, and also made use of the Morse key, in combination with the telephone. In Spain, owing to the mountainous character of the country, the whole telegraph equipment was of the lightest description, and carried on pack animals.

A statement of what might be expected from the telephone in its present development having been made, and suggestions made as to its employment, it only remained, said the author, to touch on certain drawbacks attending the use, or rather the improper use, of both telephone and telegraph, classing the two together under one head. In a recent article published in the *Proceedings* of the United Service Institution it was stated that "the employment of this technical auxiliary in the first line restricts the high mobility of present warfare." It is possible, and even probable, that the telephone would often create unnecessary correspondence. The ease with which communications could be held would offer temptation to the more feeble to seek the shelter of non-responsibility, to the wavering increased facilities for vacillation, and to some others improved openings for making their presence (in the spirit) felt when least desirable. All this, no doubt, the writer had in his mind—in fact, he saw centralisation encouraged by the telephone. But there was another side to the picture. In a very remarkable article published by the Institution in 1887, and entitled the "March and the Battle," the following gave the keynote :—"The little influence thus possessed by the Commander-in-Chief in choosing the occasion for decisive action is really an element of great difficulty in the warfare of the present day." The whole of the article appeared a most forcible argument, unintentionally, but unmistakably, showing the necessity for a wide extension of the telegraph. The urgent demand for that unity of action almost, if not altogether, lost under the conditions of modern war ; "a great united effort instead of a number of isolated blows." The history of the telegraph was a series of brilliant records of its achievements. "Technical art is striving hard to discover fresh means for enlarging the influence of those in supreme command," and the telephone was its latest effort.

CORRESPONDENCE.

COMPOUND WINDING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : It may be of interest to mention that the four compound-wound dynamos designed by Mr. Gisbert Kapp, and built and erected by Messrs. Crompton and Co. in 1882 at Berechurch Hall, were successfully run in parallel. As the load varied, each machine was switched on or off to a common pair of mains, and reversal guarded against by the now well-known method, at a "parallel switch-board." I am unaware to whom the credit of originating this arrangement is due. Another less important feature was the employment of a main reversing switch for changing the polarity at the mains, with the idea of lengthening the life of the lamps, then, as now, a burning question. There was also an effectual mechanical device which enabled the governor to pull up the engine to something below its normal speed on the sudden removal of a heavy load, such as would be caused by a main fuse melting, or the failure of main driving belt. Altogether it may fairly be claimed that this pioneer installation was more than "up to date."—Yours, &c.,

J. W. KEMPSTER.

Belfast, April 18, 1892.

TRADE NOTES AND NOTICES.

Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892.

The tenth annual edition of the above well-known annual is now ready, price 7s. 6d.; post free, in the United Kingdom, 8s. 3d.; abroad (with the exception of a few countries), post free, 8s. 10d.

The edition consists of between 900 and 1,000 pages, and special care has been taken to make the Directorial division of the book, which has been considerably extended, thoroughly accurate and reliable. In this respect no possible comparison can be made with any similar publication.

To the Handbook division has been added several features which will be found of service to the Electrical and Allied Trades. The Digest of the Law of Electric Lighting has been thoroughly revised and brought up to date, and the most recent Board of Trade Regulations are also included. The various tables and tabulated statements have been remodelled and amplified; and a new feature is the tabulation of valuable information respecting Electrical Limited Liability Concerns.

The profession will find "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK a trustworthy work of reference, and purchasers of plant and apparatus may confidently turn to its pages for the names of all the principal firms supplying their requirements. Nearly every firm of any standing in the Electrical and Allied Trades is represented in its advertisement pages.

A digest of the contents of the book will be sent on application.

TENDERS INVITED.—The Gas Supply and Electric Lighting Committee of the Town Council of Glasgow are inviting tenders for excavating, trenching, and the laying of cast-iron troughs for electric conductors. Tenders, duly marked, have to be in by Tuesday next, the 26th inst., to Sir. J. D. Marwick, City-chambers, Glasgow.

TENDERS ACCEPTED.—The tender of Messrs. Hammond and Co. has been accepted for laying down the electric plant for the public supply of electricity at Burton-on-Trent.

——— The Nottingham Castle Museum Committee have accepted the tender of the Brush Electrical Engineering Company (Limited) for the electric lighting of the new Art Gallery in the Castle by incandescent lamps. 18 tenders were sent in.

PARTNERSHIPS DISSOLVED.—The partnership previously existing between Rammage, Gordon and Co., of Victoria Mansions, Victoria-street, S.W., engineers, has been dissolved. The debts of the firm will be paid by Mr. C. G. Gordon.

——— The partnership existing between Messrs. Blakeney and Rennie, of Glasgow, mechanical and electrical engineers, has been dissolved. Debts will be paid by Mr. J. Rennie.

MUIR, MAVOR, AND COULSON (LIMITED).—We are asked to point out in reference to the voluntary liquidation of the above Company that this does not in any way affect the contracting business carried on by Messrs. Mavor and Coulson at 56, George-square, Glasgow.

ELECTRICAL AUTOMATIC DELIVERY BOX COMPANY (LIMITED).—Mr. F. G. Painter (of the firm of Tribe, Clarke, Painter and Co.), the official liquidator of this Company, will, with the sanction of Mr. Justice Kekewich, pay a first and final dividend of 1s. 8½d. per share on and after the 19th inst., at his offices, 19, Coleman-street, E.C. Creditors have previously received 20s. in the £.

CITY OF LONDON ELECTRIC LIGHTING (PIONEER) COMPANY (LIMITED).—In the matter of the voluntary winding-up of this Company, a meeting will be held at the offices, 1 and 2, Great Winchester-street, London, E.C., on the 19th May next, at 3 o'clock, for receiving an account of the winding up.

REMOVAL.—The Pretoria Lighting Company's London transfer office has been removed to 29, Holborn Viaduct, E.C.

DIVIDENDS IN BANKRUPTCY.—A second and final dividend of 2s. 5¾d. in the £ will be paid at the offices of Mr. C. J. Singleton, 8, Staple Inn, E.C., on April 29th, in the matter of J. W. Gray and Son, Electrical Engineers, &c., of 115, Leadenhall-street, E.C.

CHICAGO EXHIBITION, 1893.—We again call attention to the fact that the Royal Commission are now enabled to announce that no charge will be made for space in the British Section. Intending exhibitors should lose no time in applying for space to Sir H. Trueman Wood, Society of Arts, John-street, Adelphi, W.C.

ELECTRIC SOLDERING, &C., APPARATUS.—Messrs. Pyke and Harris are showing at the Weymersch Electric Battery Syndicate's Stall No. 113, at the Crystal Palace, an electrical apparatus for soldering, boiling, or heating, the invention of J. K. Ritter of Basle.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

March 29, 1892.

6,112. H. H. LAKE. London. Improvements in and relating to secondary batteries or accumulators. (W. Sleicher, Jun., and G. A. Mosher, United States).

6,119. M. CATTORI. London. Improvements relating to electric railways

March 30, 1892.

6,122. E. C. RUSSELL. London. An improvement in the construction of electric arc lamps.

6,145. E. M. BOYNTON. London. An improved electric railway system.

6,152. T. FIELD, JNR., J. WORSFOLD AND H. S. D. BRAYN. London. An improved material or fabric for applying magnetic, galvanic or other currents for curative or medical purposes.

6,181. L. G. WOOLLEY. London. Improvements in or relating to automatic electric fire-alarms.

March 31, 1892.

6,246. W. W. BEAUMONT. London. Electro-magnetic variable speed gearing.

6,253. A. S. CHURCHILL. London. Improvements in apparatus for propelling vehicles by electricity upon railways and tramways.

6,259. E. BAILEY. London. Improvements in the manufacture of filaments and other light emitting bodies for electric glow lamps and apparatus therefor.

April 1, 1892.

6,287. E. BÖHN. London. Improvements in incandescent lamps.

6,289. J. C. GRAHAM. Birmingham. Improvements in the deposition of metals by electrolysis, and in apparatus therefor.

6,293. J. GIBSON. Kilmarnock. Improvements in motors and dynamos.

6,312. C. W. HILL AND E. HUGHES. Manchester. An electrical apparatus for starting gas engines and other prime movers.

6,313. T. G. HARTLAND AND J. EVANS. Manchester. Improvements in receptacles for electric and other wires, gas piping and the like.

6,344. C. J. BARLEY AND M. FEETHAM. London. Improved apparatus for straining or taking up slack in wires, cables, strips, or the like, more especially intended for straining electric conductors between their supports.

6,345. H. NEHMER. London. Improved electric hammer for denta and other purposes.

6,348. W. S. SMITH AND W. P. GRANVILLE. London. Improvements in electrical relays.

6,364. H. H. LAKE. London. Improvements in electric arc lamps. (H. Wilbrant, Belgium).

April 2, 1892.

6,402. G. FORBES. London. Improvements in the means of preventing interference of electric currents used in tramways, telephones, &c.

6,405. D. URQUHART AND J. M. SMALL. London. An improvement in secondary voltaic batteries.

6,428. E. HANCOCK AND A. J. MARQUAND. London. Improvements in the manufacture of elements for electric or secondary batteries.

April 4, 1892.

6,465. G. E. HEYL. London. Improvements in electrical secondary or storage batteries.

April 5, 1892.

6,551. C. L. JAEGER. London. Improvements in electric recording devices for mariners' compasses and other instruments.

6,569. J. E. KINGSBURY. London. Improvements in telephone cables.

6,579. M. DERI. London. Improvements in alternate-current electro motors.

April 6, 1892.

6,629. SIEMENS BROS. AND CO., LIMITED, AND F. JACOB. London. Telephone call apparatus.

6,635. A. S. BOWER. London. Improvements in or connected with moulds for casting ribbed metallic plates; more especially intended for use for casting plates for secondary batteries.

6,637. G. E. HEYL. London. Improvements in electrodes for storage batteries.

April 7, 1892.

6,688. C. D. RICHARDSON. London. An automatic self locking quick break switch.

6,694. G. J. SPALDING AND R. L. HAWKINS. London. Improvements in electric hair and skin brushes.

6,693. H. G. JACKSON. London. Improvements in and relating to dynamo-electric machines, electric motors, continuous-current transformers, and the like.

6,705. G. HUGHES. London. Improvements in insulators. (B. V. Vermorel, France.)

6,707. G. KAPP. London. Improvements in the method and apparatus for registering supply of electricity.

Digitized by Google

6,720. J. A. Kingdon. London. Improvements in dynamo-electric machines.
6,722. W. W. Donaldson and R. Macrae. London. Improvements in battery plates or secondary batteries.

April 8, 1892.

6,725. G. E. Tucker. London. The manufacture of electrical fires.
6,726. R. Pippette. London. Improvements in multiple switchboards for telephone exchanges.
6,775. T. Higginson-Wolstencroft. London. A new or improved electrical apparatus.
6,785. L. B. Stevens and W. R. Sykes. London. Improvements in electrically controlling the levers of railway signal interlocking apparatus.

April 9, 1892.

6,839. J. E. Bott and C. G. Norris. London Improvements in means for electro-plating the interior of tubes and other hollow articles.
6,861. G. Binswanger. London. Improvements in electrical heating apparatus.
6,868. R. C. Kintzing. London. Improvements in dynamos or motors.
6,870. A. D. Monies. Liverpool. Holding telephone receivers (viz., that part of a telephone through which the communication is heard) against the ear.

April 11, 1892.

6,888. W. L. Spence. Manchester. An improved conduit system for electric conductors.
6,911. W. J. Davy. London. Improvements in change over mechanism for electric arc lamps.
6,954. R. J. Crowley and W. Walker. Liverpool. Improved means of producing motive power and electricity.
6,961. A. Heil. London. Improvements in automatic switches for electrical apparatus.

April 12, 1892.

6,989. J. A. McMullen. London. Improvements relating to conduits, applicable for combined use as casings for electrical conductors and for gas supply, or for either use separately.
7,003. R. J. Charleton and H. Walker. London. Improvements in coal-cutting machines, with special reference to electrical motive power.
7,004. A. Wallace. London. Improvements in electrical cooking apparatus.
7,008. W. A. Heyes. London. Improvements in electric light fittings.
7,009. H. Skipper and H. J. Pierce. London. An improved telephone transmitter.
7,016. J. McFarlane and W. B. Edgar. Glasgow. Improvements in electric fittings.
7,029. G. G. M. Hardingham. London. Improvements in electric cables.
7,037. R. Belfield. London. An improvement in electric arc lamps.
7,044. E. J. Wood. London. Improvements in dynamo-meters.
7,081. J. D. Hickman. London. Improvements in telephone and electric signalling circuits between trains and signal boxes.

April 13, 1892.

7,095. J. Sugden and W. J. L. Sandy. London. Improvements in electric arc lamps.
7,126. A. Wright. Brighton. Improvements in electrical distribution.
7,142. E. A. Kruger. London. An improved method of renewing incandescent electric lamps.
7,144. G. H. Cutting. London. Improvements in secondary batteries.

April 14, 1892.

7,170. T. E. Weatherall. Greenwich. An improvement in primary batteries.
7,172. S. R. Bradley. London. Electrical surgical instruments.
7,173. A. Whalley. Helsby. An improvement in electric signals.
7,206. A. A. Voysey. Liverpool. Improvements in or connected with connections or couplings for electric and other cables and ropes.
7,220. F. B. Stone. Belvedere. An improved primary battery.
7,235. R. J. Charleton and H. Walker. London. Improvements in coal-cutting machines, with special reference to the application of electrical motive power.
7,237. B. S. Paterson and J. B. Furneaux. London. Improvements in commutators for electrical machines.
7,252. R. E. B. Crompton and W. A. Chamen. London. Improvements in electrical distributing apparatus.
7,253. T. Duffy. London. Improvements in generating electricity and producing air in a luminous state, and in apparatus therefor.
7,264. H. T. Harrison. London. Improvements in electric arc lamps.

April 16, 1892.

7,275. H. W. Miller. London. Improvements in electric meters.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1891.

3,570. George. Electrotherapeutic apparatus.
4,794. J. E. Kingsbury. London. Signalling and telephonic systems.
5,338. Crampton and Essinger. Electric arc lamps.
5,989. Lancaster. Electric lighting.
6,633. Teagut. Electric meters.
8,031. Howard. Electric heating, &c.
8,126. Philpott. Dynamo-electric machines.
8,378. South. Electric current circuits.
8,450. Snell. Connecting electrical conductors to surgical, &c., instruments.
9,079. Hoeffner. Electrolytic extraction of meta's, &c.
9,423. Grenfell. Electric incandescent lamps.
16,270. Thompson. (Correns). Electric accumulators.
17.655 Burton and others. Heating metals by electricity.
18,290. Lundberg. Electric switches.
22,352. Painter. Electric switches.

1892.

177. Painter. Electric drop lights.
2,254. Thompson. (Fuss.) Incande cent electric lamps.
2,329. Imray. (Montgomery.) Bleaching by electrolysis.
2,330. Gimingham. Electric switches.
2,458. Pool and Others. Dynamo-electric generators, &c.
2,913. Nahnsen. Electro-metallurgic extraction of zinc.
3,542. Lake. (Gray). Telephonic apparatus.

COMPANIES' MEETINGS & REPORTS.

Eastern Extension, Australasia, and China Telegraph Company (Limited).

The following report of the Directors of this Company for the half-year ended December 31st last will be submitted to the thirty-seventh ordinary general meeting, to be held at Winchester House, E.C., on Wednesday, May 4th, at 2 p.m.

The gross receipts, including Government subsidies, have amounted during the half-year to £243,658. 8s. 10d., against £279.095. 1s. for the corresponding period of 1890. In the latter figures, however, £8.031 was included for profit on exchange, whereas a loss of £3,232 had been experienced during the past half-year, in addition to which the receipts have been diminished by the reduction of rates to Australia, to which further reference is made below.

The working and other expenses, including £22,031. 17s. 6d. for cost of repairs to cables and expenses of ships, absorb £74,314. 8s. 5d. against £74,000. 3s. 2d. for the corresponding period of 1890, leaving a balance of £169,343. 19s. 5d. From this is deducted £3,092. 2s. 10d. for income tax, and £31,895 for interest on debentures, debenture stock, and contribution to sinking fund, leaving as the net profit for the half-year £134,356. 16s. 7d. Against this £2,535. 4s. has been charged for special expenditure, as shown in the revenue account, leaving a balance of £131,821. 12s. 7d., which, with £92,665. 9s. 7d. brought forward, shows an available balance of £224,487. 2s. 2d.

One quarterly interim dividend of 1½ per cent. has been paid for the half-year, and it is now proposed to distribute another of like amount, making, with the interim dividends paid for the first half-year, a total dividend of 5 per cent. It is also proposed to pay a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent, for the year 1891. The balance of £111,987. 2s. 2d. has been carried to the general reserve fund, which, after being credited with interest and debited with £191,163. 2s. 4d. on account of the cable expenditure, now stands at £428,842. 7s. 4d.

In accordance with the provisions of the Trust Deed, dated May 15, 1879, 337 of the Company's Five per Cent. Australian Government Subsidy Debentures, amounting to £33,700, were drawn by lot on the 4th instant for payment at par on July 1st next.

The "Guarantee" arrangement made with certain of the Australasian Governments for testing the effect of a 4s. rate to Australia has now been in operation for eleven months, with the result that the number of words transmitted has increased 43 per cent over the corresponding period of 1890, and 60 per cent. over that of 1889, the year taken as the basis of the "Guarantee," while the revenue has diminished at the rate of £55,000 per annum. By the terms of the agreement one half of the loss is borne by the guaranteeing Colonies, and the other half by the Associated Companies and the Indo-European Department of Her Majesty's Indian Government, according to their respective interests in the Australasian traffic. As the experiment, as far as it has gone, is considered not unsatisfactory, it has been decided to continue it for another year.

Numerous interruptions have occurred on the Company's system during the past half-year, but owing to most of the cables being duplicated, the traffic has not been materially affected, except with Manila, which was unfortunately cut off from telegraphic communication for several weeks, the cable between Hong Kong and Cape Bolinao having broken at each end of the line during a severe typhoon. Negotiations have since been entered into with the Spanish Government for the duplication of the cable, and it is hoped that a satisfactory arrangement may be shortly brought about. All the cables are now in good working order.

Digitized by Google

During the half-year under review the Company's system has been extended to Sumatra in accordance with the arrangement concluded with the Netherlands Government, and referred to in the last report. The cable for this connection was taken from the Company's stock at Singapore, and the cost of the operation (£14,924) has been debited to the reserve fund. A contract has also been entered into with the Netherlands-Indian Government for the manufacture and laying, on account of the Government, of a submarine cable to connect Acheen with the Company's system at Sumatra, and an arrangement has been made with the Telegraph Construction and Maintenance Company for carrying out the work.

The shareholders having at the last meeting approved the principle of establishing a staff pension fund, your Directors are having the details worked out by experienced actuaries, and a scheme will be submitted to the meeting for dealing with the matter, together with a formal resolution empowering the Directors to carry out the necessary arrangements.

In accordance with the Articles of Association, John Denison Pender, Esq., and the Most Honourable the Marquis of Tweeddale retire by rotation, and, being eligible, offer themselves for re-election. The retiring auditors, Mr. Henry Dever and Messrs. Welton, Jones and Co., also offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

ELECTRIC CYCLE SYNDICATE (LIMITED).—This Company was registered on April 12th with a capital of £3,000, in £1 shares, by Goldring, Mitchell, and Phillips, 20, Abchurch-lane, E.C. The objects are to purchase or otherwise acquire letters patent, inventions, rights, and privileges (subject to royalty or otherwise) in connection with electrical or mechanical inventions or improvements, whether in the United Kingdom or abroad; to carry on the business of electrical and mechanical engineers; to buy, sell, manufacture, repair, convert, let out on hire, trade and deal in electrical and mechanical appliances, and all or any kind of apparatus or appliances used in connection therewith; and to experiment and test with the object of propelling cycles and other vehicles by means of electricity, and for the purpose of utilising electricity for any or every other purpose. Registered without Articles of Association.

ORIENTAL TUBE COMPANY (LIMITED).—This Company has been registered with a capital of £30,000, in £5 shares, to acquire the business of engineers and tube manufacturers, carried on by W. W. Davies, at West Bromwich, Staffs., and elsewhere.

BIRMINGHAM HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED).—The annual return of the above-named Company, made up to January 11th last, was filed on the 13th inst. The Company, was registered on June 26, 1889, with a capital of £100,000, divided into 19,900 ordinary and 100 founders' shares of £5 each. At the time of making-up, 107 shares (100 founders' and 7 ordinary) had been taken up, of which the founders' shares had been issued as fully paid to the House-to-House Electric Light Supply Company (Limited). Upon the remaining 7 ordinary shares no calls have been made.

Lancashire and Cheshire House-to-House Electricity Company (Limited).—The annual return of this Company, made up to January 11th, was filed on the 13th inst. The Company was registered on June 26, 1889, with a capital of £100,000, divided into 19,900 ordinary and 100 founders' shares, of £5 each. At the time of making-up, 107 shares (100 founders' and 7 ordinary), had been taken up, of which the 100 founders' shares had been issued as fully paid to the House-to-House Electric Light Supply Company (Limited), similarly with those of the Birmingham Company. Upon the remaining shares no calls had been made. In this and the following six Companies, the shareholders are the original subscribers, and each Company has the same shareholders.

Manchester House-to-House Electricity Company (Limited).—The annual return was made up to January 11th, and filed on the 13th inst. The capital is the same, and the particulars relating thereto are precisely similar to the preceding and following House-to-House Companies.

Midland House-to-House Electricity Company (Limited).—See preceding remarks.

Northern House-to-House Electricity Company (Limited).—See preceding remarks.

Scottish House-to-House Electricity Company (Limited).—See prepreceding remarks.

South of England House-to-House Electricity Company (Limited).—See preceding remarks.

Western House-to-House Electricity Company (Limited).—See preceding remarks.

CORLETT ELECTRICAL ENGINEERING COMPANY (LIMITED). — An agreement made on April 2, 1892, between George Stephen Corlett, of Wigan, electrical engineer, of the one part, and John C. Kenyon, of Wigan (as trustee for and on behalf of the above-named Company), of the other part, states that whereas the said George S. Corlett has carried on the business of electrical engineer in co-partnership with Mansell Mercier for some years past at Wigan and Bolton, and that this partnership has been dissolved as from January 1, 1892, the said George S. Corlett continuing the business; and whereas the above-named Corlett Electrical Engineering Company (Limited) has been incorporated with a capital of £10,000, in £10 shares, it has been agreed that George S. Corlett shall sell, and the Company shall purchase, all the properties, plant, goodwill, &c., of the old firm for the sum of £750, and such further sum as the certified value of the stock-in-trade, goods, and effects. The purchase-money to be satisfied by the allotment of 100 shares of £10 each, fully paid up, to the said G. Corlett or his nominees, and the balance of the purchase-money within one month of the date of the agreement. George S. Corlett is to be Managing Director of the Company for a period of ten years from the date of its formation, with remuneration varying as the paid-up capital of the Company and dividends paid thereon vary. The purchase shall be completed as from March 31st last.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The annua return of the above-named Company, made up to April 5th, was filed on the 14th inst. The Company was registered on November 8, 1872, with a capital of £130,000, in £10 shares; and by special resolution, passed July 3, 1874, and confirmed July 17, 1874, the Directors were authorised to purchase the submarine cable laid between Barcelona and Marseilles; and, for effecting the purchase, the capital of the Company was raised to £190,000 by the creation of 6,000 new shares of £10 each, which were to be entitled to a fixed preferential dividend of 10 per cent. per annum. By special resolution, however, passed September 30, 1886, and confirmed October 19, 1886, it was resolved that, in consequence of the abandonment of the Company's original cable, the capital of the Company should be reduced from £190,000 (represented by 6,000 £10 per cent. preference and 13,000 ordinary shares of £10 each) to £95,000, by the writing off of £5 per share. At the time of making-up (the capital having remained the same), 12,931 ordinary and 6,000 preference shares had been taken up. Upon the ordinary shares £4 per share had been called, and upon the preference shares the full amounts have been called. All calls have been paid, amounting so £81,724.

LIVERPOOL ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of the above-named Company, made up to March 18th, was filed on the 9th inst. The Company was registered on January 10, 1883, with a capital of £10,000, in £5 shares, and by special resolution passed July 10, 1885 and confirmed July 27, 1885, the capital was raised to £200,000 by the addition thereto of 38,000 new shares of £5 each. At the time of making up all the shares had been taken up, and upon 10,000 shares the full amount had been called, while upon the remaining 30,000 shares £3 per share had been called. The calls paid (including £8,243. 10s. paid in anticipation of calls) amount to £148,243. 10s., leaving nothing unpaid.

RAILWAY ELECTRICAL FOG SIGNAL SYNDICATE (LIMITED).—An agreement made Oct. 27, 1891 (filed Feb. 26, 1892), between Wm. Andrews (who is called the vendor), of Nottingham, electrician, of the one part, and Joseph Press, junr., on behalf of the Company, states that the vendor had an interest in letters patent, No. 18,747, of 1889, for "Improvements in railway signalling apparatus," and was owner of the letters patent, No. 14,181, of 1890, for "An improved electrical fog signal for railways;" and it was agreed that the vendor should sell, and the Company purchase, the said patents and the full and exclusive benefit thereof, and of all extensions of the same, and of all improvements and all further inventions in connection with the said letters patent made by the vendor. The purchase consideration for the said sale was to be £9,000, to be fully satisfied by the allotment of 9,000 fully paid-up £1 shares in the said Company. An agreement of the same date gives the Company similar rights and benefits over certain foreign and colonial letters patent, similar in character to the above, for the further consideration of £9,000, in paid-up shares of £1 each in the Company. The Company was registered on November 12, 1891, with a capital of £25,000, in £1 shares, with objects as indicated in the above agreements.

CITY NOTES, &c.

A RUBBER TRUST.—The *New York Herald* announces the incorporation of the United States Rubber Company, having a capital of $50,000,000 The sponsors of the new undertaking are Mr. Charles R. Flint and Mr. Wm. Ivins, who claim that with others they have secured the control of the biggest concerns in America for the production of rubber. The Company was incorporated in New Jersey on the 29th ult., and is established to do a manufacturing and mercantile business. It will manufacture and deal in all kinds of rubber goods. The rubber industry is rapidly developing in the United States of late, and it is claimed that the amount of business has trebled during the past 20 years, and that two-thirds of all the rubber produced in the world is consumed in the States.

ANGLO-ROMAN CAB COMPANY.—At the recent general meeting of this Company in Rome a dividend of 12 per cent. was declared for 1891. The profits of the electrical department for 1891 were £2,000 more than those for the previous year.

BELL TELEPHONE COMPANY.—At the annual meeting of the Bell Telephone Company, held in Boston on the 29th ult., it was decided to increase the capital from £3,000,000 to £4,625,000. The net earnings of the Company were £625,364, against £573,884 for the previous year.

BRIGHTON AND HOVE ELECTRIC LIGHT COMPANY (LIMITED).—This Company are issuing first mortgage debentures of £100 and upwards, up to £15,000.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended April 17th were £734, as against

Digitized by Google

£816 for the corresponding period of last year, being a decrease of £82. The total receipts to date, from January 1st last, amount to £12,817, against £11,729 in the corresponding period of 1891, being an increase of £1,088.

DIVIDENDS DUE.—*April 23:* DIRECT UNITED STATES CABLE COMPANY, 3s. 6d. per share (free of income-tax).

GREAT NORTHERN TELEGRAPH COMPANY OF COPENHAGEN.—The balance-sheet of this Company for the year to December 31st last shows gross receipts, including a balance of £48,216 brought forward from the previous year, £359,646, and expenditure £65,448. Interest and amortisation of debentures absorb £21,250, the interim dividend of 5 per cent. £75,000, and a further dividend of 7s. 2d. per share £54,166. A sum of £83,333 has been placed to the reserve fund, and a balance of £56,169 is carried forward. The total assets of the Company now amount to £2,816,255.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the fortnight ending April 15, 1892, amounted to £2,673, as compared with £3,661 in the corresponding period of last year, a decrease of £988.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended April 15, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £2,746.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 728.—Vol. XXVIII. FRIDAY, APRIL 29, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The occasion of the taking up of the nominal load was celebrated at the Regent's Park station of the St. Pancras Vestry on Wednesday last. The engine-room was crowded with visitors, who divided their attention between electric frying-pans and dynamos, some few penetrating as far as the boiler-house, and most of them looking as if they took an intelligent interest in the switch-board. A supply station is not perhaps the most convenient place for an afternoon party; but a visit to the St. Pancras station is a visit to a thoroughly successful concern, and one of which both the engineers and the Vestry may be proud.

The "taking-up" of the nominal load allows the management to estimate the revenue which may be expected from the present supply; and although there was primarily no intention of making a profit, the undertaking has shown a very fair prospect of financial success. Now that the plant is fully occupied at night, endeavours are being made to secure a better day load, and the Electricity Committee recommend that a special day supply should be provided by a separate meter at 3d. per unit. This is cutting the margin very fine if that price be compared with the sheer cost of the present supply; but the plant is there, and steam must be kept up, so that the extra expense besides coal would be very small. There is then every reason to expect that, as long as the day and the ordinary supply do not overlap during fogs and winter afternoons to such an extent as to overload the machinery, the increased revenue will not only pay for the larger output, but will allow the charge for the ordinary supply to be reduced.

Judging by the bulky batch of leaflets which we have received from the New Telephone Company, this rising hope of schismatic and unsatisfied London telephone renters is about to vigorously canvass the metropolis. On the one hand we have this sanguine competitor for our favour *promising* an underground twin-wire and efficient service, with trunk connection to the North, for £14 per annum, the first 5,000 subscribers to be taken on at only £12. 12s., and no charge whatever to be made until 3,000 instruments are actually in connection through the Exchange; and, on the other hand, we have the National Telephone Company, with its £20 subscription and its overhead single-wire much-grumbled-at service. At first glance, therefore, the bait looks exceedingly attractive. But the promises of youth are notoriously not to be relied upon; and the New Company, though old in years, lacks the chastening influence of wide practical experience.

The rates now proposed by the New Telephone Company are already higher than those originally suggested, and apply only to lines within one mile of the nearest Exchange; so that the National Company has only to slightly level up its service and to slightly level down its rates to render serious competition almost out of the question. In any case, the New Telephone Company will have deserved well of the country should it confine itself to "alarums and excursions," and by mere threat of competition lighten the burden of the metropolitan telephoning public. Perhaps, however, the New Company hankers after a more substantial reward. It need not despair even of that, for much is within the reach of the skilful tactician.

Mr. Preece supplies us this week with a striking example of the throttling action of iron pipes when used to protect cables carrying alternating currents. In the instance given, one hundred feet of this cable, when the full load was put on the mains, produced a drop of volts of 13 per cent, or about twenty times that due to the mere resistance of the leads. The publication of the full particulars is opportune in connection with the recent work of Professors Ewing and Thomson on eddy currents, for the fall of volts, large as it is, is not nearly so great as ordinary calculations would indicate, owing to the screening action of the eddy currents formed in the pipe. The thickness of the iron in these pipes was over five millimetres, or more than twice that of the thickest plates alluded to in Professor Ewing's recent article; and it appears that under these circumstances the magnetic force in the middle of the iron was only one-thirtieth of its skin value, and that the mean magnetisation of the pipe was only a sixth of the value it would have if the iron were non-conducting. The only way to reduce these losses for electric light circuits is to place the going and return cables in the same iron pipe, for the thickness of the iron cannot well be diminished. For telegraphic and telephonic circuits the loss of power is of course unimportant, but the need for rapid and clear signalling naturally leads to the same conclusion.

The expressions given by Profs. Ewing and Thomson for eddy current losses are of great value, but they are too

Digitized by Google

cumbrous and difficult for rapid calculations, and engineers will accordingly welcome the simple working rule given by Dr. FLEMING in this issue. In transformers, where it is necessary to laminate the iron very thoroughly, it appears that for all practical purposes the losses can be very simply expressed in terms of the thickness of the plates, the frequency of the current, and the maximum induction density used. The divergence of the formula from the actual value probably differs for various types of transformers, but appears to be too small to be worth considering.

THE formulæ of Profs. EWING and THOMSON are explicit; they rely on no unknown coefficients, and are cumbered with no arbitrary constants; they are composed of quantities well known to all electrical engineers, though these quantities are not perhaps handled in a popular fashion. Dr. FLEMING supplements these formulæ by one which may be called implicit, not in the sense of infoldedness and complication, by any means, nor in the mathematical sense; but signifying that it must be tacitly received on the word of its author. Coefficients are indeed conspicuous by their absence; they seem to have cancelled each other. Dr. FLEMING's formula is thoroughly Molesworthy, and is likely to find its way straight into the drawing office.

BY the acceptance on the part of the Government of Sir E. BIRKBECK's resolution urging the electrical connection of our coastguard and signal stations with lifeboat and rock-apparatus stations, and the appointment of a Royal Commission to investigate the further question of cable communication with lightships and rock lighthouses, it may be taken that the country is at last committed to something definite and practical. The Post Office, Sir JAMES FERGUSSON tells us, has the matter in hand, "showing that it has gone beyond the stage of contemplation;" estimates have been framed of the cost of telephonically connecting the coast-guard stations from the Isle of Wight to Lynmouth, and the work of framing estimates for communication all round the coast is being pushed on; meanwhile immediate steps are to be taken to run wires to the more exposed points.

ONE of the most satisfactory applications of the electrical transmission of power is the use of motors for hoisting. Cranes, travellers and lifts are intermittent in their action, and present few difficulties in driving. The use being intermittent, a motor can easily compete with a gas engine or small steam engine if a continuous supply of current can be drawn upon. A considerable number of travellers are now in use in machine shops. The construction of electrical cranes and capstans has met with great success, and several lifts are in constant use in this country, and succeed, in London, in competing with hydraulic supply. Unlike electric traction, there should be no difficulty in settling beforehand exactly what duty has to be performed by hoisting machinery. The travelling crane which is described in another column presents no very remarkable features, but gives a fair specimen of this kind of work. The complications of inertia and gradient do not present themselves in this problem, and this branch of electrical engineering is not hampered by any master patents.

THE specifications issued in connection with the electric lighting of the streets of Melbourne, which were printed in our issue of January 29, appear to have excited the sorrowful indignation of the great firm of Siemens and Halske. Asked by their Australasian agents to send in tenders they replied that they "could not consent to such a plan as the one proposed," and learnt with regret that it was intended to use "high-tension continuous current to run the arc and incandescent lamps in series." This system, the letter went on to say, was "based entirely on American principles, especially on constructions of the Thomson-Houston International Company;" the firm had given the matter their best consideration, and had decided that if they sent in tenders they would be defeated "on account of the prices of the inferior manufactures of the competitors." In conclusion Messrs. Siemens and Halske remarked that "it would be a pity if the Australian towns should subject themselves to American influence." Running incandescent lamps in series is certainly not in accordance with European practice, but running arcs in parallel would, we venture to think, be equally contrary to Australian notions.

A LINE drawn from Lowestoft to Littlehampton cuts off an important slice of this island, and that slice was at Easter time provided with a telegraphic service little better than was to be found by JULIUS CÆSAR when he landed thereon in B.C. 55. A few hundred thousand pounds would suffice to lay a network of trunk lines underground. Most of the Post Office lines run along the railways, and there would be no special difficulties in the way; but no amount of money would compel a Wheatstone instrument to work through such an underground network; and although the cost of repairing the damage done by the storm of 1886 and by the snow and gale of this Easter would go far towards the expense of a buried system, it would only be a stand-by in the event of breakdowns, and would not in any way replace the existing lines.

Personal.—Mr. Albion T. Snell has been appointed a member of Section III. (Dynamos and Motors) of the Crystal Palace Electrical Exhibition Jury.

Royal Victoria Hall.—Mr. Vernon Boys will lecture at the Royal Victoria Hall, Waterloo Bridge Road, on Tuesday, May 3rd, on "Flying Bullets."

Glasgow and West of Scotland Technical College.—Mr. Andrew Stewart has presented a handsome screw-cutting lathe to the electrical engineering laboratory connected with this College. The machine was made by Messrs. John Lang and Sons, lathe manufacturers, Johnstone.

The Engineering Exchange.—We are informed by the Secretary that the Engineering Exchange opens on Monday next, May 2nd, at 12 o'clock. The opening meeting will be in the Exchange Room of the Jerusalem (Limited), Billiter House, Billiter-street, E.C., where the committee have secured preliminary accommodation. All parties interested in engineering are invited to attend at the opening.

The Incandescent Lighting of the Chicago Exhibition.—According to the *Western Electrician* of April 16th, the Thom-

Digitized by Google

son-Houston and Edison Companies have put in amended tenders for furnishing the incandescent lights required for the Chicago Exhibition, on the ground that they misunderstood the specifications. On April 9th a 50 per cent. reduction had been made by these Companies on the sums originally demanded (see *The Electrician*, April 22nd, p. 651). The demands of these Companies were, however, still considered too high by the Exhibition authorities.

Glasgow.—The electric fire-alarms made by Munro's Electrical Manufacturing Company, Glasgow, which the police authorities of that city were the first to adopt, and which are now so prominent over all the leading public thoroughfares of Glasgow, have just been ordered to be supplied to the city of Londonderry. It is said that the Liverpool municipal authorities are considering a proposal for their adoption.—Prof. A. B. W. Kennedy paid a visit to Glasgow last week, in connection with the central station which is being rapidly run up.

Johannesburg.—The Johannesburg Electric Lighting Company is now actively running additional wires, and over a thousand lamps are about to be added to those at present in use. Several houses, hotels, shops, &c., are being wired and fitted up by Mr. R. Lewis Cousens, the South African manager of Messrs. Woodhouse and Rawson. The same firm is also importing electric rock drills. The Thomson-Houston International Electric Company is also actively pushing its mining wares, Mr. Chas. Cohen, the agent of the Company, offering to lay down electrical plant for tramming quartz and other material, and to guarantee a minimum saving of 25 per cent. on the present method of animal traction.

Portsmouth.—Mr. Arnold Taylor, one of the Local Government Board Inspectors, held an inquiry on Wednesday last week in connection with the application of the Town Council to borrow £60,000 for the carrying out of Prof. Garnett's electric lighting scheme. Prof. Garnett, who explained the scheme, said Portsmouth was in a somewhat unique position on account of the extent of the area which came under the provisions of the Order, for in any case they were obliged to lay mains at least a mile from the central station to cover the area. The system he proposed to adopt was known as the high-pressure alternate-current system, with primary mains at 2,000 volts pressure, in connection with street transformers and a low-pressure secondary network.

Jardine Automatic Time Check.—An automatic electric time check has been devised by Mr. C. K. Jardine, of Demara. It consists of a box containing a drawer divided into two compartments, into which the workmen's numbered checks fall through a slot. When the hour for starting work comes round, the hands of a clock, making suitable contact, actuate an electro-magnet, which pulls an armature. This armature holds up a lever by means of a catch, and displays a card bearing the word "early" before a little window. When, however, the armature is attracted, the lever is released, and the word "late" is brought into view. The same mechanism also causes the checks to fall either into the "early" or "late" compartments. The apparatus is set by pulling out the drawer to withdraw the checks.

The "Guarantee" Cable Tariff to Australia. — The "Guarantee" arrangement made between certain of the Australian Governments and the Eastern Extension and other Telegraph Administrations for testing the effect of a 4s. rate to Australia has now been in operation for eleven months, with the result that the number of words transmitted has increased 48 per cent. over the corresponding period of 1890 and 60 per cent. over that of 1889, the year taken as the basis of the "Guarantee," while the revenue has diminished at the rate of £55,000 per annum. One-half of this loss is borne by the guaranteeing Colonies, and the other half by the Associated Companies, and the Indo-European Department of Her Majesty's Indian Government, according to their respective interests in the Australasian traffic. As the experiment, as far as it has gone, is considered not unsatisfactory, it has been decided to continue it for another year.

The Brussels Municipal Electric Lighting Contract.—The Brussels Municipality, as our readers are already aware, has been considering the electric light question for some years, and tenders have several times been invited. Finally, in October last, specifications were again duly drawn up and tenders once more invited. The following companies responded:—The Compagnie Internationale d'Electricité (Liége), the Allgemeine Elektricitäts Gesellschaft (Berlin), Schuckert (Nuremberg), Ferranti (Limited), Crompton and Co. (Limited), and the India Rubber, Gutta-Percha and Telegraph Works Company, of Silvertown. The Electricity Committee, after having considered the report of the three experts who examined the tenders, came to the conclusion that the financial condition of Brussels did not warrant the outlay necessary for the construction of a 10,000-light station, and a fresh tender for a 5,000-light plant was asked for from the India Rubber Company, and it is this last tender which the Committee are about to recommend the Conseil Communal to accept.

Electric Lighting in Time of War.—In a letter to *L'Industrie Electrique*, M. Marius Poirier relates some interesting experiences which he recently had in Chili. M. Poirier was sent out to Chili in charge of an electric lighting and transmission plant for the Santiago Exhibition. Just as the Exhibition was about to close the civil war broke out, and one Sunday morning M. Poirier received a telegram from the Minister of the Interior at Valparaiso, ordering him to betake himself immediately to that city. On arriving at Valparaiso M. Poirier was told to instal without delay a projector at Fort Boreas, commanding the Bay of Valparaiso. After an hour's search in the arsenal a Siemens projector was unearthed; a 12 H.P. threshing engine was then borrowed, and a Ganz Δ^3 dynamo was brought up from the Exhibition at Santiago (140 miles distant) by special train, together with a supply of posts and wires, and thirty-two hours after the receipt of the telegram the plant was at work, and ran well for six months until the projector was blown to pieces by a shell.

City and Guilds of London Institute. — The annual meeting of the governors and friends interested in the Institute was held at Mercers' Hall, Cheapside, on Wednesday; Lord Selborne presiding. The report showed that the income for the past year had amounted to £30,940, made up as follows:—Subscriptions and donations, £22,715; school fees and sundry amounts received from students, £8,225. The total expenditure had been £30,226. The amount voted by the council for the Central Institution at the beginning of the year was £12,000, and the expenditure £11,489; the students' fees amounted to £4,086, and the net cost of the Institution, after deducting the students' fees, &c. was £7,403. The amount voted by the council for the maintenance of the Finsbury Technical College was £8,794, and the expenditure there had been £8,786. The students' fees amounted to £3,032, and the net cost of the College, after deducting students' fees, &c., was £5,754. The expected income available for general purposes for the present year amounted to £31,870.

Electrical Measuring Instruments.—At a meeting of the Institution of Civil Engineers on Tuesday last, Mr. James Swinburne read a Paper on this subject. The Paper consisted mainly of a critical description of instruments. All volt-meters and ampere-meters, said the author, should be direct reading; milled heads and co-efficients were not admissible in modern electric light instruments. Volt-meters should absorb as little power as possible, as every watt taken was equal to the interest on £1. Horizontal dials and suspension fibres or compass points were to be avoided. Permanent magnets fell into undeserved disrepute a few years ago; but it was now more generally realised that they could be safely employed in instruments of the highest class. The meter was a most important instrument, as the whole profit or loss of a station depended on its accuracy. The chief faults in commercial meters, besides inaccuracy, were:—(1) Not starting until a large load was on; (2), absorbing power in shunt circuits; (3), absorbing power in the main circuit and reducing the light of the lamps; (4), getting out of order through the use of mercury; (5), needing frequent winding up; (6), wearing out through rapid movement of working parts; (7), stopping on account of insects or damp; (8), costliness.

The Proposed San Francisco-Honolulu Cable.—The Government steamer Thetis, says the *Western Electrician*, is about to sail from San Francisco for Honolulu to complete the survey for the proposed submarine cable to the Hawaiian Islands. The Albatross commenced the work, and went so far as to make soundings over and back, when it was decided that she would be more valuable in Behring Sea, and the instruments and apparatus for sounding were transferred to the Thetis—a proceeding that delayed the work considerably, for the Thetis is not a vessel so well fitted for this class of service as the Albatross. The Thetis will follow the same general direction, filling in where it seems to be needed to ascertain more definitely the nature of the bottom of the Pacific. In the final plotting of the survey the lines laid down by the Albatross and the Thetis will be considered in conjunction with the much earlier one laid down by the Tuscarora. The Thetis will start from Point Conception and finish its survey at the Hawaiian end at Hilo. The Thetis is expected to complete its work in about six weeks, and then the Hydrographic Office will begin its charts, which will serve as a basis for the recommendation of the Navy Department for the line which may one day connect the American continent with the islands in the Pacific.

Another Transformer Patent.—American electrical engineers, says *Industries*, are somewhat uneasy at the issue of a patent to Deprez and Carpentier for transformer distribution, or rather transmission. It may be remembered that in the Gaulard and Gibbs case an old abandoned specification by Deprez and Carpentier was put in as an anticipation. Under a delightful system of patent law these dreamers, who never did any real work in transformer distribution, may pose as the inventors, provided they apply within two years of the date of actual use of transformers in America. If we are not mistaken, they have a monopoly of seventeen years, not beginning when they originally dreamed or even when they filed their American patent, but beginning now some fourteen years after the date of their European patents. Apparently an inventor should not apply at once for an American patent. He should apply, say, in Belgium, where there is no examination, and fees are low. He should then wait, and if, say, twenty years later, industry in the United States takes such a turn that his invention, or something like it, comes into use, he should wait eighteen months or so more, and then file an application. This is "hung up" by the Patent Office for, say, ten years, and he finally has seventeen years' monopoly after that, so that the whole trade is in his hands. The Americans thus really give Deprez and Carpentier a thirty years' monopoly—for that is what it really comes to if the patent be held to be good.

The New Telephone Company.—We have received copies of the papers now being issued by the New Telephone Company for the purposes of the canvass which they are undertaking in London. The New Telephone Company offer their London subscribers trunk line communication with Manchester, Liverpool, Glasgow, and all the important towns in Great Britain. Subscribers in the most distant towns, it is said, will be able to talk with each other from their own offices and private residences, the instruments fitted serving both for local and trunk communications. As it is the intention of the Company to adopt universally the twin-wire system, and to put that system, as far as possible, underground, it is considered necessary to name a somewhat higher tariff than was originally suggested. The rate provisionally fixed is an inclusive annual rental of £14, but the first 5,000 connections for which agreements are signed will be accepted at £12. 12s. per annum, on agreements for one, two or three years at the option of the subscribers. No charge whatever will be made to those subscribers who may be first joined up until 3,000 instruments are actually in connection through the exchange. These rates are, however, only applicable to lines not exceeding one mile in length from the nearest exchange; longer lines will be charged proportionally to their length at the rate of half the initial charge per mile. The Metropolitan area will, however, be so laid out that lines exceeding one mile in length will be very exceptional. Copies of testimonials from leading subscribers to the Company's Manchester Exchange, and extracts from the recent speeches delivered in the House of Commons by the Postmaster-General and the Chancellor of the Exchequer, are also being sent out.

Obituary.—We much regret to announce the death from pneumonia, following influenza, of Mr. Charles Hortsek, M.Inst.E.E., which took place on the 21st inst., after only a week's illness. Mr. Hortsek was a native of Hungary, and was at one time in the service of Messrs. Ganz and Co., of Buda Pesth, but had been many years in England and the Colonies. At the end of 1881, as soon as Mr. E. H. Johnson had determined on the nature of the Edison exhibit at the Crystal Palace Exhibition, Mr. Hortsek was placed in charge of the wiring, and continued in charge till it was completed. Many will remember the extraordinary effect produced by what was felt to be the great feature of that successful Exhibition, the huge floral electrolier, provided by Messrs. Verity, the switching in and out of which—now so simple and unmasked—carried away the audience night after night. We are apt to forget the novelty of that Exhibition, but those who visited the Crystal Palace frequently will know that even to-day no one can carry out wiring in a more perfect manner than was effected by Mr. Hortsek. He afterwards went to the Cape of Good Hope and wired the Houses of Parliament, under the auspices of Mr. W. H. Preece; these were the first Houses of Parliament lighted by electricity. He was then sent to India, by Edison's Indian and Colonial Electric Company, to introduce incandescent lighting there. Arrangements had been made with the head of Government telegraphs to make a complete experimental installation of 100 lamps, on which work Mr. Hortsek was engaged when he became very ill. The doctors said that his life depended on his leaving India as soon as possible, and he had no choice but to abandon the work and return to England. He was during the last two years in the service of the Westminster Electric Supply Corporation, and was in charge of their system of conductors and street mains. He was a most zealous and indefatigable worker, and of great natural ability, and was highly esteemed and respected by all who enjoyed his acquaintance.

Governing Water Wheels in Electric Railway Service.—The Ottawa Electric Railway Company, says the *Western Electrician*, operates a line consisting of eight miles of double and four miles of single track. The system was constructed in seven weeks, and cars were put into service in the latter part of June last year. The equipment consists of 16 cars of the vestibuled type, and the Westinghouse system is employed, single-reduction 20 H P. motors being used. Power is obtained from the famous Chaudière Falls, two turbines driving two 100 H.P. Westinghouse compound dynamos, a third machine being kept in reserve. At first the turbines raced seriously when the load was thrown off. Now, however, the water-wheel gates are raised and lowered instantly by a mechanical arrangement, and a resistance load is kept on the dynamos. The mechanical device consists of a right and left hand lever which operates a shifting belt, which in turn operates a gear wheel on each of the water-wheel gates, so as to rapidly lift or lower them. This contrivance solved the problem for ordinary fluctuations, but not when only a few cars were in service. To overcome this difficulty an electrical regulator was resorted to. A large tank was constructed, and into it a stream of water is kept constantly running. Five coils of iron wire, in shunt with the trolley wire, are placed in the tank and connected to a grouping switch. The amount of current diverted through the coils is, for the five movements of the switch respectively, 25, 50, 75, 100, and 125 amperes. The energy consumed, then, with the lever on the last notch at 500 volts is equal to about 84 H.P. The man on duty watching the voltmeter has the belt-shifting water gate controlling lever on his right, and the current diverting switch on his left. The electrical device is only used occasionally, early in the morning and late at night. The voltmeter is connected with the centre of distribution, a mile distant, so that regulation for the centre of distribution is secured without regard to drop in the feeders. There would be an objection to the employment of an automatic device in combination with the electrical arrangement, in that practically a constant load would be maintained on the dynamos. The apparatus was designed by Mr. T. Ahearn, of the Chaudière Electric Light and Power Company of Ottawa.

TRANSFORMER PREDETERMINATIONS.*

BY DR. J. A. FLEMING, M.A.

(Concluded from page 655.)

We shall now point out another means by which the magnetising current can be approximately predetermined if the total loss in the core is known.

If hysteresis and eddy current energy loss were entirely absent from the core, it is clear that the whole energy conveyed to the primary circuit of a transformer on open secondary must be simply dissipated in heating the copper of the primary circuit; and hence, if this copper loss is also small the actual power given to the transformer would be zero. Under these circumstances the phase of the primary currents would be very nearly 90° behind that of the impressed electromotive force. If an iron core so well laminated that eddy current is practically absent is employed, then it will still be the case that the instant of the maximum value of the periodic primary current will be coincident with the instant of zero primary electromotive force, even though the form of the primary current curve may be very different from that of a simple sine curve. This is true even though the magnetisation of the core is carried up very much above the "knee" of the magnetisation curve.

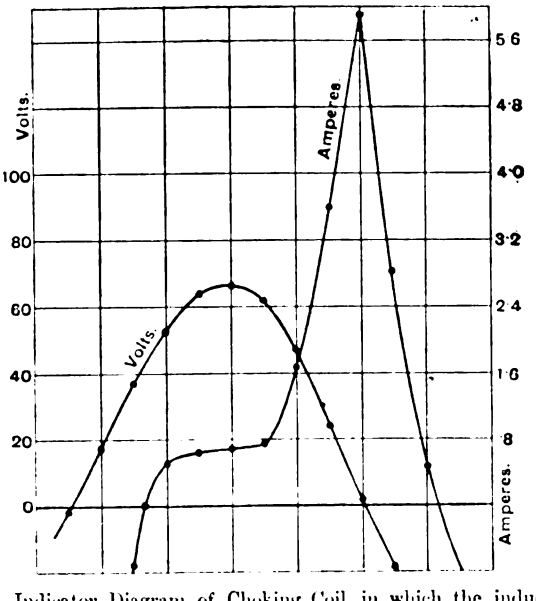

FIG. 1.—Indicator Diagram of Choking Coil, in which the induction is carried up to about 17,000 or 18,000 C.-G.-S. units.

In Fig. 1 is shown the indicator diagram of a small choking coil, or transformer with no secondary circuit. The core was composed of fine iron wire, No. 36 gauge in diameter, wound up into a ring. The ring was wound over with insulated wire, and the choking coil† so formed had an indicator diagram taken by Ryan's method. The dimensions and data were as follows:—

Mean diameter of ring core	8·9 cm.
Area of cross section of core	3·14 sq. cm.
Mean length of magnetic circuit	26·5 cm.
Maximum induction density in core...	17,800 C.-G.-S.
Number of turns of wire.....	200
Resistance.....	Negligible.
Frequency	92
Impressed E.M.F. maximum value ...	65 volts.
Mean loss in the core	·33 watt per c.c.

In this fine wire core eddy current loss is practically absent at this frequency, and from the diagram it is seen that although the current curve is very far indeed from being a sine curve, yet its maximum value, of 5·9 amperes, happens at the instant of zero electromotive force. Another such diagram for a similar core is shown in Fig. 2. In this case the induction density is not carried up so high, but the same fact may be noted, viz., that the maximum value of the current happens at the instant of zero electromotive force. If we next consider the action of the eddy currents, we shall find that their presence in the core always causes the phase of the primary current to be advanced or brought back more into consonance with that of the impressed electromotive force.

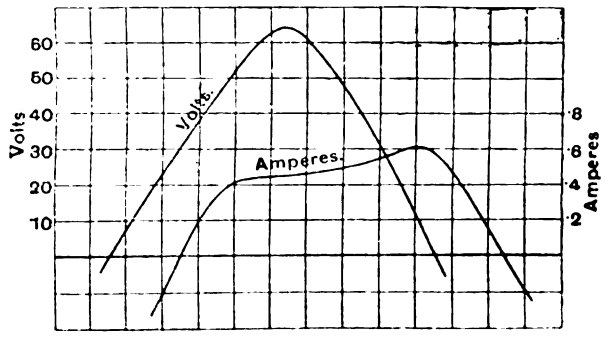

FIG. 2.

The diagram in Fig. 3 is the indicator diagram of a choking coil composed of a solid cast-iron core wound over with 200 turns of wire of negligible resistance. The ring had a mean diameter of 8·6 centimetres, and a cross sectional area of 2·7 square centimetres. An alternating electromotive force having a frequency of 195 was applied to the circuit, and the diagram of current taken by Prof. Ryan. In this case the eddy current loss is very marked. From the observed value of the induction density **B** and the primary current (i), a diagram of core losses was formed (*see* Fig. 4), the outer curve being the (**B**, i) curve, and the inner curve the curve of static hysteresis deduced from separate observations. In the diagram in Fig. 4 the vertical divisions each represent 0 0038 of a gauss, and the horizontal ones each represent 4 amperes.

The whole area of the outer curve reckoned in gauss-amperes or joules is nearly 0 8 joule, and this is, therefore, the whole energy wasted in the core in one complete magnetic cycle. Since the frequency is nearly 200 the whole loss of power in the core is nearly 160 watts. From the dimensions of the ring we find easily that the total volume of the iron is 73 cubic centimetres. The diameter of the cross section of the ring is $\sqrt{3·44}$ centimetres. The maximum value of the impressed electromotive force was 26 volts, and that of the induction density 4,930 C.-G.-S. units. The frequency was 195.

The magnetic permeability of cast iron corresponding to an induction of 5,000 C.-G.-S. is nearly 200. If we attempt to calculate the current through the circuit when a periodic electromotive force, having a maximum of 26 volts, is applied to the coil, we shall find that we get a value far below the

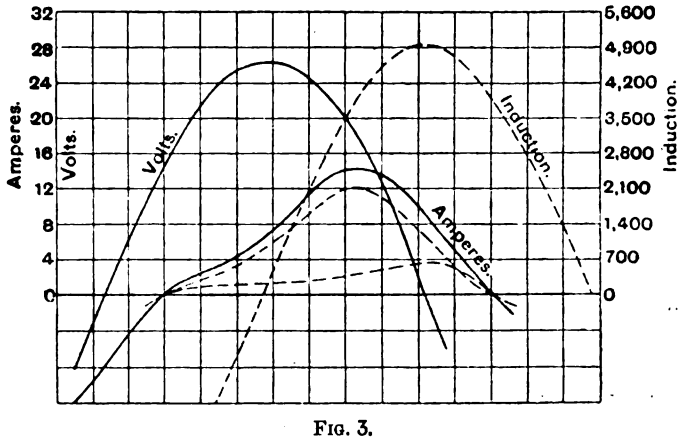

FIG. 3.

observed value. For if we insert in formula (7) the proper values, viz., $E = 26$, $l = 27$, $n = 195$, $S = 2·7$, $N = 200$, and $\mu = 200$, we get

$$I = \frac{10^9 \times 27 \times 26}{8 \times 9·87 \times 2·7 \times 200 \times (200)^2 \times 195} = 2 \text{ amperes},$$

whereas the observed maximum value of the current is about

* These articles form part of Vol. II. of "The Alternate Current Transformer in Theory and Practice." All rights reserved.

† One of the coils employed in some experiments by Messrs. Fortenbaugh and Sawyer.

Digitized by Google

14 amperes. This is because the immense eddy current loss renders the choking coil virtually a transformer with a closed secondary circuit.

We shall now proceed to point out an empirical rule which will in nearly all cases enable the total core loss to be predicted when the so-called "magnetising current" is given, and *vice versâ*, provided that the iron circuit is a closed circuit, and that the iron is fairly well laminated. Under these circumstances the total loss in the core can be calculated from the core dimensions and from the secondary electromotive force. If the reader will refer back to *The Electrician*, January 22, p. 296, in which is shown the harmonic analysis of the primary current of a transformer on open secondary, he will see that the current curve can be analysed into a principal sine curve which lags one-eighth part of a phase behind the impressed electromotive force, and also into two smaller components. The principal sine curve has a maximum value a little less than that of the actual current curve. The mean power given to the transformer during one period is obtained by taking the mean of the values of the equally-spaced instantaneous currents and corresponding electromotive forces. It is quite evident that

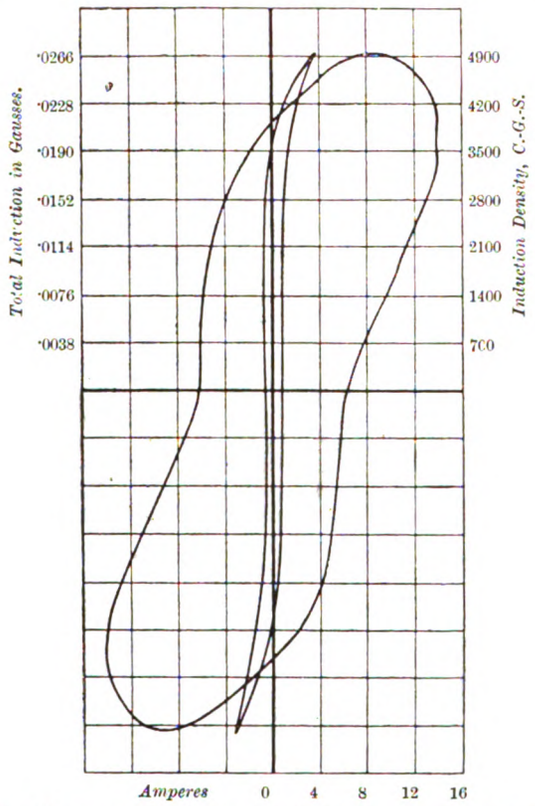

FIG. 4.—Diagram of Static Hysteresis (*Inner Curve*) and Total Loss (*Outer Curve*) for a Cast-Iron Ring. (Number of turns of wire in ring, 200; section of ring, 2·7 sq. cm.)

it is possible to so place a true sine curve of current with reference to the electromotive force curve that the mean power represented by this equivalent sine current is the same as that due to the actual current. It is also evident that a simple sine curve having the same maximum ordinate as the real current curve, but placed one-eighth part of a complete period in phase behind the impressed electromotive force curve, would, if it represented a current, be equivalent in mean power to the actual current. Let E be the maximum value of the electromotive force, and let it vary in a simple, periodic manner. Then $\frac{E}{\sqrt{2}}$ is the $\sqrt{\text{mean}^2}$ value of this electromotive force. It is the value which would be read on a Cardew voltmeter or a dynamometer. In the same way if I is the maximum value of the equivalent simple periodic current of equal power value with the real current, $\frac{I}{\sqrt{2}}$ is its $\sqrt{\text{mean}^2}$ value. If θ is the angle of phase difference between E and I, and W is the true value of the power given by the currents I, we have

$$\frac{E}{\sqrt{2}} \frac{I}{\sqrt{2}} \cos\theta = W.$$

It is convenient to call W the *real watts*, and the simple product of the $\sqrt{\text{mean}^2}$ values of E and I, viz.: the product $\frac{E}{\sqrt{2}} \cdot \frac{I}{\sqrt{2}}$ the *apparent watts*. The cosine of the angle of lag in this case is the ratio of real to apparent watts.* The apparent watts are the simple product of the volts as measured by a hot wire or Cardew voltmeter, and the current as measured by a Siemens dynamometer. In nearly all cases of closed iron circuit transformers with fairly well-laminated cores it will be found that the ratio of the real watts, or true mean power taken up in the core when the transformer is on open secondary circuit to the apparent watts, or product of the primary working volts and the magnetising current as read on the usual instruments, will be a number not far removed from 0·75, or somewhere between 0·7 and 0·8; that is to say, near to $\frac{I}{\sqrt{2}}$. This number is the cosine of 45°, and the rule in effect comes to this:—The real power taken up in the core is that which would be given to the transformer, if we suppose the magnetising current to be a simple sine curve current, and to lag about 45° behind the impressed electromotive force. In order to show that this is so, we shall compare the actual power taken up in the core (which includes, of course, any small loss in the primary circuit) of transformers on open secondary circuit with the product of the $\sqrt{\text{mean}^2}$ values of the primary electromotive force and the magnetising current, and show that the ratio is in all cases not far from $\frac{1}{\sqrt{2}} = 0{\cdot}707$.

Transformer tested.	Primary volts. $\sqrt{\text{mean}^2}$ value = E.	Primary (magnetising) current. $\sqrt{\text{mean}^2}$ value = I.	*Real watts*, or true mean power taken up in the transformer (core) on open secondary circuit = W.	*Apparent watts*, or product of E & I, = W^1.	Ratio $\frac{W}{W^1} = P$. = *power factor.*
Westinghouse 1 H.P.	1,000	0·14	95·7	140	0·68
Mordey ..... 8 H.P.	2,400	0·07	126	174	0·72
Stanley ..... 2 H.P.	1,000	0·053	37·5	53	0·707
Westinghouse 2 H.P.	1,000	0·061	48	61	0·79
Slattery ..... 2½ H.P.	1,000	0·056	45·5	56	0·81
National ..... 2½ H.P.	1,000	0·112	75·0	112	0·67

The results from many other closed magnetic circuit transformers tested are in the same direction, and show that for most ordinary types of well-laminated closed iron cores the relation between primary volts, magnetising current, and total loss in the transformer on open secondary circuit is expressible by the empirical formula

$$\textit{Primary volts} \times \textit{magnetising current} \times P = \left\{ \begin{matrix} \textit{Total loss in watts} \\ \textit{in transformer.} \end{matrix} \right.$$

The volts and current values being the $\sqrt{\text{mean}^2}$ values or the dynamometer values; and the constant P having a value varying from about 0·7 to 0·8. It is convenient to call P the *power factor* of the current.

The power factor for a closed magnetic circuit transformer on open secondary is never far from 0·75. Hence we have a simple practical rule, viz., the real power lost in the transformer so worked is three-quarters of the apparent watts supplied to it.

* When a current curve is a true sine curve, its *lag* with respect to another true sine curve representing electromotive force or current has a definite meaning. If it is not a true sine curve then the *lag* of its maximum value and of its zero value is not the same thing.

Digitized by Google

In cases where the eddy current loss is very large, as in the case of the cast-iron ring above mentioned, the *power factor* in the above formula is much more nearly unity than 0·7. Thus, for the cast-iron ring (Fig. 3, *ante*), the $\sqrt{\text{mean}^2}$ value of the current is 8·6 amperes, maximum value being 14 amperes. The $\sqrt{\text{mean}^2}$ value of the primary electromotive force is 18·5 volts, and $18{\cdot}5 \times 8{\cdot}6 = 159$. The apparent watts are therefore 159, whilst the real watts taken up were found to be 160. On the other hand, for open circuit transformers, when on open secondary circuit, the *power factor* is found to be much less than 0·7, often as low as 0·1.

In connection with this point it may be useful to point out that the total eddy current and hysteresis losses in well-laminated soft-iron cores can be predetermined with sufficient accuracy for most purposes by very simple formulæ. Prof. J. J. Thomson has given (see *The Electrician*, April 8th, p. 599) a complete investigation of the behaviour of iron rods or plates under alternating magnetising force. The formulæ given for the eddy current and hysteresis losses involve some handling of hyperbolic trigonometry in applying them to practical work. For any cases likely to occur in practice, viz, when the rods or plates of iron are less than 1 millimetre in diameter it can be shown* that if X is the thickness of the plate in mils (1 mil = ·001 in.), n is the frequency and B the maximum mean value of the induction, then the loss in watts per cubic centimetre W in that iron under such alternating force is given by the expression

$$W = \left(\frac{X\,n\,B}{10^8}\right)^2 + \cdot 002\,n\,B^{1\cdot 6} \quad . \quad . \quad . \quad . \quad (1)$$

where the first term expresses the eddy current loss, and the second the hysteresis loss. Compare, for instance, the results of this simple formula with the results derived from the application of the complete investigation of Prof. Thomson, as given by Prof. Ewing (in *The Electrician* of April 15th, p. 634) for maximum inductions of 4,000, 6,000, 8,000, and wrought-iron plates ½ mm. and ¼ mm. thick. The formula above (1) gives the predetermined losses as follows, for a frequency of 100 :—

Plates ¼mm. thick.

Losses in watts per cubic centimetre.

B.	Eddy.	Hysteresis.	Total.	(True.)
4,000	0·016	·012	0·136	·012
6,000	0·036	·022	0·256	·028
8,000	0·064	·035	0·414	·044
	Plates ½mm. thick.			
4,000	0·064	·012	0·184	·018
6,000	0·144	·022	0·364	·039
8,000	0·256	·035	0·606	·064

The results in the last column marked (True) are those calculated by Prof. Ewing from Prof. Thomson's formulæ. For plates 1mm. thick and B = 4,000, the approximate formula gives the total loss equal to 0·0376 watt per cub. cm., and the true formula gives it 0·0379. Hence, for practical calculations and predeterminations, the above very handy rule can often take the place of the more difficult one in predetermining core losses in transformers.

WHY SOME PACKING DOES NOT PACK.†

BY ROBERT GRIMSHAW.

In order to make an engine that will pack well, there must be considerable depth of stuffing-box, and the gland must not be so deep, proportionately, as to fill it up and make it impossible to put more than about two coils of packing into it. Not one engine in three on the market has a deep enough stuffing-box and proportionately short enough gland. The Straight-Line Engine Company get along for quite a while without any packing at all, because they have about four rod diameters in length in their box, and that is bushed with Babbitt metal, leaving an annular orifice of very slight thickness so long that the steam cannot find its way out before the back-stroke is completed and the pressure removed.

For the same reasons that call for deeper stuffing-boxes most of those that we see are of too slight diameter, leaving no chance to get in rings of sufficient size. With from 50 to 100 per cent. greater space between rod and stuffing-box wall, rings could be used which, by gentle pressure, would be perfectly elastic and would make steam-tight joints without absorbing undue power in friction, and without undue wear of packing and rod.

A further error made by some engine-builders is the use of glands that are driven in by two bolts, one each side of the rod. Of course this is a lighter and cheaper construction than the screw principle, but at the same time it often results in the gland being cocked and the rod worn too much on the sides, while there may be blowing on the other two quarters of the rod's circumference. Any engineer can stop almost any engine with this type of gland, by merely tightening up on one of the bolts. In fact, he can without much trouble do the same thing with many of the screw type, too—which should give him a lesson on the difference between packing and jamming.

After getting the packing in, whether it is cut right or not, and whether or not it has grit on it, there is a chance of injustice being done to it and its maker by its being set up too hard. For every case where a box is too loosely packed there are about three that are set up too hard, with the three-fold bad effect of consuming power, scoring the rod, and wearing out the packing too fast. Reference to the remarks about jamming the valve-stem by cocking the gland or setting it up too hard is appropiate in this connection. Packing is often set in wrongly, care not being taken by the engineer to break joints, so that where it is cut badly there is a nearly straight steam-way through which leakage is very easy.

It will usually be found best for the engine tender to run the gland up hard at first, before the engine turns over, then slack it back until there is just a tiny leak of steam—a gentle puff, during the first day ; then the second day it may be set up a mere trifle, so as to leave only the faintest suspicion of a leak ; and if I had my way about it I should let this little leak show as long as the packing was run. What steam came out through so slight a crack would cost but little, and the wear of the rod and packing would be less, while the power consumed by friction would be more than enough to pay for the steam. Besides this there is some slight lubricating power in the steam and water.

* The proof of this is given in full in the forthcoming Second Volume of the "Alternate-Current Transformer," from which this article is taken.

† Abstract from the *India Rubber World* of New York.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-NIGHT) FRIDAY, April 29th.

INSTITUTION OF CIVIL ENGINEERS.

7.30 p.m. Students' Meeting. Paper to be read: "The Steam Hammer and its Relation to the Hydraulic Forging Press." By H. H. Vaughan, Stud. Inst.C.E.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Physiology of Dreams." By Dr. B. W. Richardson, F.R.S.

MONDAY, May 2nd.

ROYAL INSTITUTION.

5 p.m. Annual Meeting.

SOCIETY OF ENGINEERS.

7.30 p.m. Ordinary Meeting. Paper to be read on "Dry Crushing Machinery." By S. H. Cox.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture, V., 1. "Recent Bacteriological and Chemical Research in Connection with the Fermentation Industries." By Percy F. Frankland, F.R.S.

TUESDAY, May 3rd.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "Electrical Measuring Instruments." By James Swinburne. At this Meeting the monthly ballot for members will be taken.

WEDNESDAY, May 4th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "The Bradford Corporation Electricity Supply." By James N. Shoolbred.

THURSDAY, May 5th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Chemistry of Gases." By Prof. Dewar, F.R.S.

INSTITUTION OF MECHANICAL ENGINEERS.

7.30 p.m. President's Address and Papers to be read.

FRIDAY, May 6th.

INSTITUTION OF MECHANICAL ENGINEERS.

7.30 p.m. Papers to be read.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Sensitiveness of the Eye to Light and Colour." By Capt. Abney, F.R.S.

NOTICE.

The present Number of "THE ELECTRICIAN" completes Vol. XXVIII. With next week's number will be issued (gratis) the Index to the Volume.

READY NEXT WEEK.

Volume XXVIII. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad postage extra.

NOW READY.

Cases for binding Volume XXVIII., price 2/0, post free, 2/3.

The Publisher is now able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

ELECTRIC TRACTION.

The comparatively slow progress of electric traction in this country seems to be due to the fact that in the construction and equipment of an ordinary tram line only a trifling amount of mechanical skill is needed. The car-builder in arranging a short wheel-base is limited only by the conditions of balance to avoid a tip up. The springs, drawbar, and brakes are generally of the simplest and most obvious construction, and ingenuity seems to have been expended chiefly in swivelling bodies, and in the really important matter of the design of wheels and rails. Electric traction on the other hand, if it is to be successful, calls for not only a thorough knowledge of the design and construction of motors and perhaps the management of accumulators, two subjects in which nine electric light engineers out of ten are by no means well versed; but a practical acquaintance with mechanism and mechanical science that not one electrical engineer in twenty can command. Besides this, a general knowledge of tramway engineering, such as it is, and of steam economy is requisite. In the infancy of electric traction, the problem to be solved was not understood, and the experimenters were, *à fortiori*, utterly in the dark as to the proper methods to be used. Owing to the more urgent demand in America, the problem received an American solution. That is, the cars *had* to go, somehow. The perseverance, ingenuity, and expenditure on experiments were on the colossal scale appropriate to that country. One difficulty after another was attacked and surmounted, dozens after dozens of motors and gears were thrown on the scrap heap, and so long as there are more lines to be

Digitized by Google

equipped, we cannot expect American traction engineers to sit down and generalise, and state the problem which, in their own fashion, they have solved. We are likely, therefore, to be misled if we work backwards from a study of the means by which the end has been attained. Moreover, so many different systems are in use that a proper comparison of the essentials is very difficult, and the interesting experience which has been or is still being acquired in Leeds, is a warning that American electric traction is a collection of a number of details which have survived experimental work, and that under modified conditions further experiments will be needed.

A very slow, unexciting, and old-fashioned way of approaching the solution of such a problem as this is to quietly consider what it is that we want to do; or if we have, thanks to Mr. Reckenzaun, a careful account of what others have done, to give attention to such general principles as we may find in them. The electrical side of the work, if we dismiss the series system as being still too complicated and undeveloped, is very simple. The question of accumulators may be very concisely stated. It rests with one or two makers to give confidence in the endurance of the plates by a fair maintenance contract and a substantial guarantee. A considerable expenditure of ingenuity has been made upon the closed-conduit system; but the nuisance of a tramway in any form is not appreciably increased by a slot, if that be a mere extension of the groove of one of the rails. The design of a motor to deliver a given power at a given speed, or a given torque for a given current, is a mere drawing-office job. Switches for introducing resistance or altering the grouping of cells present no real difficulties, if they are wanted, while they offer a fine field for inventive ingenuity.

One of the first questions which the electrician asks is, "Why do you want two 15 H.P. motors to do the work of two horses?" It is no use asking the tramway engineer such a question, for he is not necessarily a skilled mechanical engineer. The railway engineer will not appreciate the difficulty, for he has only to notch down his links in order to start. Our American friends probably began, as most of us have done, with a three or four horse motor. This would not do; and by successive experiment it was found that a couple of 15-horse motors would not only drive the car comfortably, but in the event of the breakdown of one, the other would run the car home.

If the life of a tramcar motor could be insured, the armature would probably be calculated as being ten times more likely to burn out than that of a dynamo. The reason is simple. The starting pull is difficult to foresee, and if at a pinch a long pull and a strong pull is wanted, the armature has to stand the brunt of it in the shape of a heavy current. As the strength of a chain is the strength of its weakest link, so conversely, the size of a tram motor is fixed by the greatest effort that it is called upon to exert. Since it is current only that gives the torque required for starting, the accumulator system has some advantage, in allowing the connection of cells in various groups in parallel; and a similar benefit in a less degree is to be found in the use of more than one motor, or in the duplicate system which Mr. Holroyd Smith is using at Bradford. The use of the gearless motor in America is described elsewhere in the present issue; and Mr. Short argues that the low electrical efficiency which is inseparable from a slow-running motor is compensated by the absence of mechanical losses in gearing. As far as economy of power is concerned, it does not matter whether a direct driving motor is used with an efficiency of 60 or 65 per cent., or whether a high-speed armature with an efficiency of 80 per cent. be connected to gear with a similar efficiency. Mechanical instinct is wanted in this work, rather than electrical science. Ingenious comparisons have been made between the life, weight, cost, expense of maintenance and work of a horse and of an accumulator; and the same might be done for a motor. When some first-rate mechanical engineer can be found to give his mind to the matter, one who will not be too proud to place the electrical work in the hands of a thoroughly experienced motor builder, an English solution to the problem of electric traction will be forthcoming.

THE DETERMINATION OF CURRENTS IN ABSOLUTE ELECTRO-MAGNETIC MEASURE.

BY G. F. C. SEARLE, M.A.

(*Continued from page 609.*)

§ 77. **Correction for Finite Cross Sections.**—The ratio of the mean radius of the fixed coils to the mean radius of the suspended coil is the only quantity to be determined with the utmost accuracy in a properly designed current-weigher. The other measurements required are easily made with sufficient accuracy, since in a properly designed current-weigher, their errors only affect the result to a very small degree. We need not, therefore, give any description of Lord Rayleigh's actual measurements.

To calculate the force experienced by the suspended coil due to unit current through both the fixed and suspended coils, Lord Rayleigh made use of the formula given in §61, employing a set of tables which he had calculated by the aid of Legendre's "Tables of Elliptic Integrals." In this formula, however, no account is taken of the finite space occupied by the windings on the coils, so that a formula of correction becomes necessary. Such a formula is furnished by a theorem attributed to the late Mr. H. J. Purkiss (*see* Maxwell, *Electricity*, Second Edition, §706, Appendix II.). Let a_1 be the mean radius of the fixed coils, $2h_1$ the radial depth, $2k_1$ the axial width of the windings, supposed of rectangular section, n_1 the number of turns of wire, and let the suffix $_2$ refer to similar quantities belonging to the suspended coil; also let the attraction per unit current between two co-axal coils of radii a_1, a_2 whose planes are separated by a distance b be denoted by the symbol $f(a_1, a_2, b)$. For any given values of a_1, a_2, b, the value of $f(a_1, a_2, b)$ can be found by the aid of the formula of §61. Then as long as h, k are small, the total attraction between the coils is given by the formula

$$\frac{1}{6} n_1 n_2 \left\{ \begin{array}{l} f(a_1+h_1, a_2, b)+f(a_1-h_1, a_2, b)+f(a_1, a_2+h_2, b) \\ +f(a_1, a_2-h_2, b)+f(a_1, a_2, b+k_1)+f(a_1, a_2, b-k_1) \\ +f(a_1, a_2, b+k_2)+f(a_1, a_2, b-k_2)-2f(a_1, a_2, b) \end{array} \right\}$$

The proof of this formula does not present any difficulty to the student who can use Taylor's theorem intelligently, and is acquainted with the elements of the integral calculus. The proof of the theorem forms an excellent exercise. Lord Rayleigh computed each term separately by the aid of his table.

§ 78. **The Constant of the Instrument.**—In this way the force due to unit current experienced by the suspended coil was calculated in terms of the quantities which were observed. Knowing the force in terms of the current, Lord Rayleigh was able to reverse the process, and from the observation of the force by the current-weigher was able to deduce the value of the current. The force experienced by the coil is estimated by the weight which has to be put into the other pan of the current-weigher to preserve equilibrium. The weights used displace air, so that a small correction is necessary on this account. Remembering that the force is proportional to the square of the current we see that the relation between the current and the weights may be written

$$i = \mu \sqrt{m}$$

where m is the observed difference of weights in air necessary

Digitized by Google

to counterpoise the suspended coil when the current is reversed in the fixed coils. From his measurement of the coils, Lord Rayleigh found $\mu = 0370484$.

The difference of weights is spoken of since the readings were always taken by reversal of the current in the fixed coils, for which purpose a suitable key was provided. The difference of the weights required to balance the suspended parts in the two cases gives twice the force of attraction between the suspended coil and the fixed coils, independently of the action upon the former of any other part of the circuit, and of terrestrial or other permanent magnetism. The current usually employed by Lord Rayleigh was about one-third ampere, and the double attraction was about the weight of one gramme.

§ 79. **Method of Measurement.**—We will now explain briefly the method followed by Lord Rayleigh in taking the measurements of the current. The arrangement of the apparatus is shown diagrammatically in Fig. 55. The current was supplied by about 10 either Grove or secondary cells A, and traverses a resistance B, which can be adjusted so as to bring the current to the desired value. It then passes two or more silver voltameters arranged in series C, a rough tangent galvanometer D (convenient for a preliminary test of the strength and direction of the current). It flows round the two fixed coils F of the current-weigher in opposite directions, and finally passes through the suspended coil G, being led to and

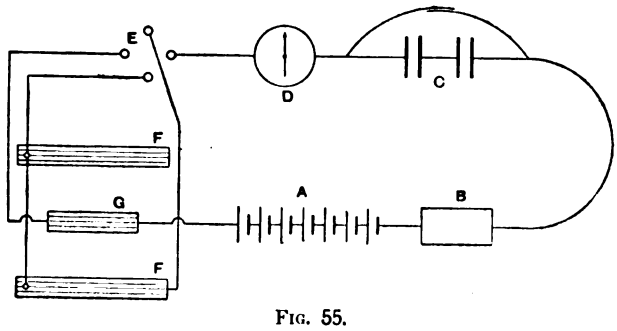

Fig. 55.

from the coil by a number of very thin flexible copper wires arranged "in parallel." At E is a commutator, by means of which the current can be reversed in the *fixed* coils. A shunt of suitable resistance was provided, so that during the preliminary adjustments the current could be diverted from the silver voltameters. The electromotive force of the storage cells (when in good order) remained almost constant during an experiment; but the gradual warming of the copper conductors caused a falling off of current, but by allowing the current to flow by the shunt for about half an hour before the beginning of the actual experiment, the temperature of the copper conductors became very nearly steady, so that in the experiment itself only a small falling off of current was found.

The direction of the current in the fixed coils of the current-weigher was reversed every few minutes by means of the commutator E, and the difference of weights on the pan of the balance required for equilibrium was noted. The weights necessary for balance (in the same position of the key) altered somewhat, both on account of the variation of the current and also from the formation of air currents due to a slight progressive warming of the suspended coil. By recording the times of each weighing two curves were plotted, from which could be ascertained what would have been at any moment the weighing in either position of the key. The difference of the ordinates gives what would have been observed if it had been possible to make both measurements simultaneously. As mentioned above, the difference of weights was about 1 gramme. The weighings were recorded to milligrammes only; but the accuracy really obtained was greater than might appear, since by anticipating somewhat the change in progress it was possible to note the *time* at which the balance demanded an integral number of milligrammes. The whole duration of an experiment was from three-quarters of an hour to two hours, measured by a chronometer; and as a weighing could be made about every five minutes there was ample material for the construction of the curves. For comparison with the deposited silver the *mean* value of the current is required, while what would be obtained directly from the curves would be the *square* of the current. The whole interval was divided into periods (usually of fifteen minutes), and the difference of ordinates corresponding to the middle of the periods was taken from the curves. The mean of the square roots of the numbers thus obtained gives a result to which the rate of silver deposit should be proportional.

Lord Rayleigh's numbers show that this relation is fulfilled with great exactness, and his work affords a very valuable confirmation of the law of electrolysis, according to which the amount of chemical decomposition is proportional to the quantity of electricity, measured electro-magnetically, which passes round the circuit. In fact, the value of $\sqrt{m}/$ (deposit per second) (*see* § 78), which according to this law should be absolutely constant, lay between the narrow limits 2413·7 and 2415 5. These numbers are derived from a table in which Lord Rayleigh included all the experiments he made, in which the manipulations were successfully conducted, and from which no experiment was excluded except in consequence of a decision made *before the result was known.*

§ 80. **Some Special Points.**—In connection with the method of taking measurements, there are a few more points worthy of mention.

It is necessary that the suspended coil should in every case be brought to rest in its proper position, corresponding to the zero of the pointer of the balance. Lord Rayleigh found it desirable to give the balance a shorter period of vibration than usual. To obtain control over the arc of vibration an auxiliary coil was introduced, through which, by the aid of a key, the current from a Leclanché cell could be made to pass. By this means a force tending to raise or lower the suspended parts could be brought into play at will; with a little practice it was possible to stop the vibrations with very little delay.

The current was led into the suspended coil by means of fine flexible copper wires. To diminish the force conveyed by these to the suspended coil, they were bent so as to place themselves naturally in the required positions before the final solderings were made. "It is important, however, to observe that no assumption is made as to the equality of these forces before and after the passage of the current. Under its influence the fine wires are, no doubt, sensibly warmed, but this effect and any consequent alterations in the mechanical properties are the same in both sets of readings, the *only* change relating to the direction of the current in the fixed coils." The reason for using a number of fine wires instead of a single thicker one is that it is much easier to bend several wires placed side by side than to bend a single wire of cross section equal to the sum of the cross sections of the separate wires. In fact, if there are n wires in the bundle, the effort of bending the single thick wire would be n^3 times that required for the bundle.

"In the absolute measurements the determination of the interval (never less than three-quarters of an hour) between the first passage of the current through the voltameters and its final cessation could readily be affected with sufficient accuracy (probably to 1/10,000), but a slight correction is called for in order to take account of the loss of time incurred at each operation of the reversing key, which controlled the direction of the current in the fixed coils (§ 79). To obtain the necessary data for this correction the main current was led through a few turns of wire surrounding a mirror galvanometer. The resulting deflection is independent of the position of the key, but at the moment of reversal the current is interrupted, and the spot of light falls back towards zero. From a comparison of the amount of this falling back with the steady deflection, in conjunction with observations of the period of vibration, it is easy to deduce the time of interruption. It proved to be less than one-tenth second, and was so nearly constant that after sufficient experience had been gained, further observations were judged to be unnecessary." The connexions for this purpose are accordingly not shown in the diagram.

(To be continued.)

NOTE ON ELECTRIC PERCUSSION DRILLS.

BY ALBION T. SNELL.

Although there has been much talk about the advantages of electric percussion drills, experience certainly seems to show that the workshop tests are not realised in practice. Many inventors have entered the field, and ingenious methods have been devised for effecting the reciprocating motion without opening the circuit; but yet drill after drill has failed to do continuous work on "headings" under the conditions of ordinary mining, although each has probably performed satisfactorily in the workshop and exhibition. The reason is not far to seek. Driving stone drifts is about as rough work as can be imagined, and the men employed are as rough as the work. So the drill must stand usage so severe that it can only be gauged by actual experience. The writer has seen an Ingersoll air-drill lying under a heap of stone that had fallen on it when the *débris* was being cleared after blasting, and which had been left in this state when the shift finished. But more important than even the rough treatment is the question of ventilation. Obviously, when driving a "heading" there is a tendency for the air to stagnate, and therefore difficulty in removing the powder fumes after the shots are fired, unless fresh air be brought continuously up to the "face." The compressed air drill exactly meets this difficulty; the exhaust from the drill causes a steady draught which cools and purifies the air; and the powder fumes can always be cleared by turning on a little air. The electric drill, on the contrary, under such conditions, tends to increase this difficulty, for the rapid reversals of magnetism soon heat the body of the drill sufficiently to materially increase the temperature of the "heading" if it be confined or the ventilation sluggish.

This disadvantage is probably sufficient in many cases to make electric drills impracticable, the mere question of cost of "boring" (gauged by working in well-ventilated spots) being altogether subordinated to other considerations. Of course, for a variety of purposes, such as quarrying, working in ventilated levels, &c., these objections have no weight. But even under these conditions the electric percussion drill has not attained much success. The reason appears to lie in the drill itself. In the first place, reciprocating magnetic devices are not efficient; indeed, solenoidal action is the least effective manner of converting electric energy; its proper function seems to be attraction through a very short range. In the early days of electric motors, designers tried to imitate the reciprocating action of the steam-engine, with results which are a matter of history. It was not till a rotary motion was insisted on that the motor became an efficient machine. *En passant*, the converse seems to hold good with the steam-engine. It is perhaps worthy of remark, too, that the most general and successful application of magnetic reciprocating action is found in the ordinary electric bell. Drills have been designed to work on somewhat similar lines (see Fig. 1). A and A_1 are two coils, so connected to the terminals *a* and *c* that the lever L will put them severally into circuit as it rests on one or the other. An iron core or plunger is attached to a shaft carrying a tappet, which works the lever *l*. This is a strong though primitive device, which would be useful in all mines having a lighting circuit, if it were not for the sparking difficulty. Various ingenious contrivances involving parallel resistances, reverse windings, condensers, &c., have been suggested, but they all fail to stand the severe shaking to which any such drill is subjected. Some time ago the writer tried amongst other methods, breaking the circuit in an air-tight box filled with oil; but the intense heat of the induction spark soon carbonised the oil. This experiment, by-the-by, showed the futility of trusting to oil insulation, when it was likely to be pierced by a spark having much energy.

An improvement on this purely electric drill is made by a single solenoid which draws in a plunger against a strong coiled spring. The blow which is given by the recoil of the spring is rapid and resembles the impact of a hammer, if the bit be at the right striking distance; and further the instroke is comparatively slow and does not shake the drill carriage excessively. A spring cushion is provided to receive the blow, in case the stroke be too short to strike the work. Such a drill, designed and patented two years ago by the writer, would have done useful work if the sparking difficulty could have been got over in a simple manner. It must be borne in mind that all direct-current drills are primarily designed to be used on lighting circuits.

A distinct advance on the above mentioned methods can be made with pulsating or alternating currents, or a combination of the two. The most apparent objection, of course, is the restriction of such drills to specially arranged circuits which are not likely to come into general use. The devices which suggest themselves are numerous; but they all have two things in common—(*a*) there is no switch, as the circuits are never opened when running; and (*b*) three or more wires are required.

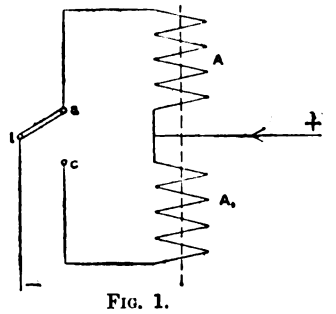

Fig. 1.

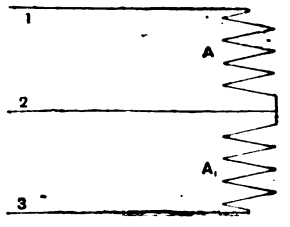

Fig. 2.

The former is a distinct gain, the latter is not so objectionable as it may appear; for if it were intended to work on this principle over a given area, three mains could be run almost as easily as two, and the service wires to the drills could be stranded into a single cable. The simplest drill of this class is one coupled to a di-phase current alternator as in Fig. 2, in which the coils A and A_1 are successively energised. An obvious objection is the fact that the instroke is made at approximately the same rate as the outstroke, and the energy of the movement is nearly the same in either direction. This defect can be remedied to some extent by decreasing the inductive effect of one coil, but it will be at the expense of energy. The Marvin percussion drill is of the double-solenoid type, and is probably the best known in America; it is run off a special dynamo with pulsating currents in separate circuits. The connections are shown diagrammatically in Fig. 3. The armature in its simplest form has only one coil, and one end of this is fixed to a continuous metal ring d_1, on which rubs a brush B_1. The other end of the coil is joined to another piece of metal, d_2, extending over about 180° and concentric with d_1. Two brushes, B_2 and B_3, placed diametrically opposite to each other, rub against it. Three connections are required, B_1 joined to the middle point of the two solenoids, and B_2 and B_3 respectively to each end. It is evident that the two coils will successively carry the current and so give a reciprocating motion. When the brushes B_2 and B_3 are each in contact with

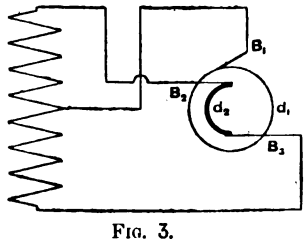

Fig. 3.

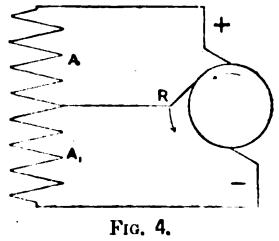

Fig. 4.

d_2, the current will divide itself equally between them (assuming the resistances to be the same) and there will be no tendency to move the drill shaft. By altering the angular length of d_2, the time between the strokes can be varied to suit different purposes. A spring buffer or an air-cushion is used to check the instroke. It is claimed that if the drill be withdrawn out of striking range of the rock, the plunger immediately loses its stroke and comes to rest near the centre of the solenoids. This result is probably attained by opening one of the circuits, and if so it is a doubtful advantage. The writer has used an india-rubber cushion for this purpose.

Mr. W. S. Aldrich recently read a very interesting Paper before the Franklin Institute treating on this subject, and

Digitized by Google

giving the results of an elaborate series of experiments with two-coil solenoids. The object of the tests was to show the varying pull in different parts of the stroke, as measured by a spring balance, equilibrium being obtained before taking each reading. He took readings, both with the coils acting in the same direction and with opposing fields. He used an ordinary dynamo, with an additional rotating brush, the arrangement being as shown in Fig. 4.

The brushes + and − are stationary, and from them a direct current flows through A and A_1. The middle wire is attached to the revolving brush *R*. When the three wires are joined the rotating brush causes first A and then A_1 to receive the full potential of the dynamo, and a reciprocating motion of the plunger results.

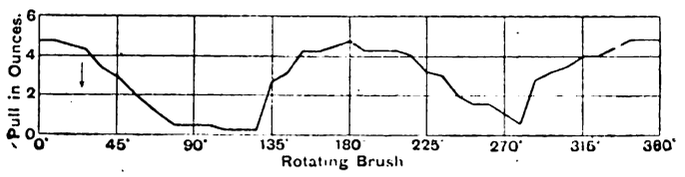

FIG. 5.

Fig. 5. shows the variation of pull through one complete stroke with the fields opposed. Fig. 6 gives the result when the coils act in the same direction.

The curves on the whole are very instructive, due allowance being made for distortions of the integrated curve of potential, caused partly by a variable dynamo speed, and partly by an irregular distribution of potential around the armature. The chief point to notice is that the arrangement shown in Fig. 5. *i.e.*, where the coils are in opposition, gives the most sudden changes, such as are required for hammer-like blows. The Marvin drill has the coils coupled in this manner. When the coils are wound so as to magnetise the core always in the same direction, the heating is undoubtedly less; but the force of the blow is less also, as the impact is not so sudden. This probably points to one of the difficulties fundamental with this class of reciprocating drill.

In order to lessen the force of the instroke with two-coil solenoids, an adjustable resistance may be placed in series with one coil; or one coil may be wound in sections which can be coupled in parallel at the end of a stroke. This latter method requires a commutating arrangement, and has been used, but the writer thinks the complication too great to be effective in practice.

Theoretically, a reciprocating motion for percussion drills is best attained by a combination of pulsating and alternating currents, as used in the Van Depoele drill. One form of the device is shown in Fig. 7. There are two fixed brushes F_1 F_2; and two revolving brushes R_1 and R_2, each pair being separated by 180deg. The coils are three in number, 1 and 3 having few turns relatively to 2; 1 and 3 are in opposition. The connections are as follows:—Coils 1 and 3 are in series,

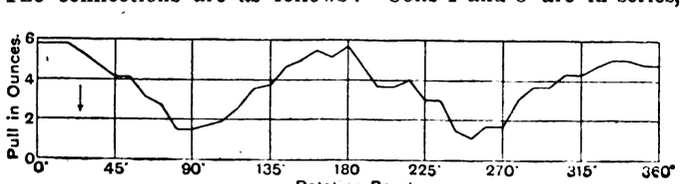

FIG. 6.

and coupled to the revolving brushes R_1 and R_2 of the dynamo; these coils are thus traversed by an alternating current. The coil 2 is coupled to the fixed brush F_1, and at the other end to the junction of coil 3 with the rotating brush R_1; it is therefore energised by a pulsating current, and exerts the chief effect on the plunger *with a constant polarity*. The movement in the direction the blow is to be given is made mainly by the action of the centre coil, the end coils practically neutralising each other. The return stroke is chiefly due to the resultant pull of the two end coils, as the current in the centre one varies between zero and its maximum. At a first glance there seems to be a departure from simplicity of design, without any compensating gain. But on a closer examination it will be seen that the instroke can be made as light and the outstroke as heavy as desired. These two points are of the greatest importance in percussion drills; and, further, the end is attained without any switch arrangement, and with only three supply mains. The writer does not know whether three-coil drills of this type get very hot when running continually; but since the magnetic induction in the plunger, although in one direction as a whole,

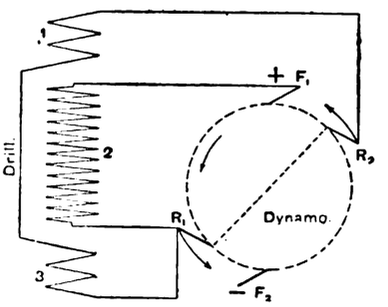

FIG. 7.—Van Depoele Reciprocating Drill

varies between wide limits, the conditions point in this direction. In fact, the iron circuit of a reciprocating drill requires to be thoroughly laminated in order to avoid serious losses from hysteresis and eddy currents; and this important point is not easily reconcilable with mechanical considerations—not to mention the commercial side of the question. The dynamos for this class of work require special modifications, which also, no doubt, introduce a further train of difficulties peculiar to them.

Viewing the percussion rock drill from its present standpoint, the writer is inclined to think that considerable improvement must be introduced before it will be widely used. The theoretical considerations are already developed to a large extent, and the conditions of practice are well known; but the drill of the future is yet to come.

ON THE RETARDATION DUE TO IRON PIPES.

BY W. H. PREECE, F.R.S.

About three years ago, when the working of the electric light installation at the Holborn Restaurant was changed from an isolated plant to the central-station system of the Metropolitan Electric Supply Company, a considerable fall of potential was observed when alternating replaced the continuous currents. This was traced to the choking effect of some iron-cased conductors which were used as service leads. It was easily cured by placing the go and return leads in the same iron casing. Particulars of this experience were not published. A similar effect occurred recently when the City of London Electric Light Company supplied current to Messrs. Mappin and Webb's establishment opposite the Mansion House. Major-General Webber has been kind enough to supply me with full particulars of this experience; and as the effects were traceable to causes which Prof. Ewing had been investigating, and of which he was such a master, I submitted them to him, with the result that he has sent me the following very interesting letter:—

Particulars as to the retardation effect apparent when separate iron pipes are used as a protection for cables carrying alternating currents, supplied by Major-General C. E. Webber.

Alternations	100 complete periods per second.
Size of conductor	19/14 ·0973 sq. in. section.
Insulation	Class K Silvertown overall diam. 0·71 in.
Length of cables	51ft. between the two testing points, making 102 ft. in circuit.
Calculated copper resistance at 60° F.	0·00884 ohm.

Each cable was placed in a separate pipe.

Internal diameter of pipe	1·25in.
External diameter of pipe	1·65in.
Length of pipe	43ft. in two pieces on each cable.

Total length of pipe, 86ft., in four pieces.

Digitized by Google

The following tests were made :—

Drop in volts between the two ends of the line.	Load in 60-watt (16-c.p.) lamps at 100 volts.
0	0
2	12
8	43
11	100
13	140
12	140

The two voltmeters used were checked together and found to fairly agree, but owing to the fluctuation of the current at the time no accurate readings could be taken.

"Cambridge, April 16, 1892.

"DEAR PREECE: The fall of potential observed by General Webber in alternate-current service wires when these are laid in separate iron pipes is rather a complicated matter. It admits, however, of tolerably complete analysis by help of the equations lately published by J. J. Thomson (*The Electrician*, April 8th), some of the uses of which were exemplified in a subsequent Paper of mine (*The Electrician*, April 15th).

"Apart from the small drop which is caused by the ohmic resistance of the conductors, there are three things that contribute, as consequences of the sheathing pipes, to bring down the volts at the distant end of the service wires :—

"(1.) First, there is the self-induction of the conductors. The presence of the iron pipes, of course, enormously increases the self-induction, making the cables in the pipes act like choking coils, and reducing the power supplied to the circuit by making the current in them lag behind the E.M.F. in the mains. In other words, the pipes give rise to an E.M.F. of self-induction which opposes the impressed E.M.F. of the supply. This is one reason why the E.M.F. measured between points beyond the sheathed parts of the service lines is less than the original E.M.F. The fall of E.M.F. due to this cause does not in itself imply a waste of energy: it only means that less energy is taken from the mains.

"(2.) Next, there is the loss due to eddy currents in the pipe. The alternate circular magnetisation of the pipe sets up eddy currents in it, and the power which is wasted in these requires that there should be a fall in the voltage on their account.

(3.) "Then, lastly, there is the loss due to magnetic hysteresis in the pipe. This again wastes energy, and requires a further fall in the voltage.

"The three effects may be calculated separately. In calculating the self-induction and the loss due to hysteresis, it has to be borne in mind that the distribution of magnetism is by no means uniform throughout the substance of the iron. With a pipe so thick as the one described by General Webber there is much magnetic screening. The eddy currents prevent the magnetic force from penetrating into the interior of the metal with anything like the intensity which the force has at the skin. J. J. Thomson's expression for the force (H_x) at any distance x from the middle of the thickness of the pipe may be written

$$\mathsf{H}_x = \mathsf{H}_0 \left(\frac{\cosh 2mx + \cos 2mx}{\cosh 2ma + \cos 2ma} \right)^{\frac{1}{2}},$$

where H_0 is the force at the skin, a is the half thickness of the pipe, and m is the quantity $2\pi\sqrt{\frac{\mu n}{\sigma}}$, μ being the magnetic permeability, n the frequency of the alternations, and σ the specific electric resistance of the iron. From measurements and tests of the sample of pipe which you sent here I find that μ is 1,000 and m (with a frequency of 100) is close upon 20. At the middle of the thickness the magnetic force has barely one-thirtieth of its skin value. The mean magnetisation of the pipe is only about one sixth of what it would be if a steady current were maintained in the conductor with strength equal to the maximum strength of the alternating current. The mean magnetic induction in the pipe, to be used in calculating the self-induction of the conductor, is

$$\frac{\mu \mathsf{H}_0}{ma\sqrt{2}} \left(\frac{\cosh 2ma - \cos 2ma}{\cosh 2ma + \cos 2ma} \right)^{\frac{1}{2}},$$

which, in the case considered, is sensibly equal to $\frac{\mu \mathsf{H}_0}{ma\sqrt{2}}$.

"Next, to calculate the eddy-current waste, the rate of dissipation of energy in eddies, per cubic centimetre of the pipe, in ergs per second, is

$$\mathrm{E} = \frac{\mathsf{H}_0^2 m \sigma}{32 \pi^2 a}$$

multiplied by a coefficient, which in the case we are dealing with is sensibly equal to unity.

"To find the loss due to hysteresis, we must first obtain by magnetic tests a set of values of $\int \mathsf{H}\, d\,\mathsf{I}$ for cycles of magnetisation, using various amplitudes of magnetising force. Then, by the expression given above for H_x, find the value which the magnetic force reaches at various depths within the metal, and so proceed to determine a proper mean of $\int \mathsf{H}\, d\,\mathsf{I}$ for the whole of the iron.

"When all this is done the total drop in volts which the iron pipe sheathing may be expected to cause will be found by adding the losses due to these three more or less independent actions.

"I have determined the magnetic constants of the pipe you sent, and have made a calculation of the several effects which, although somewhat rough, is sufficient to show that the sum of the losses is at least of the same order of magnitude as the drop which General Webber observed. It is not, I think, worth while to pursue the calculation further, for the data of the case are scarcely precise enough to make the observation serve well as a test of the theoretical work. The observation is, however, very interesting, not only on the practical side as showing forcibly the necessity of putting both conductors into one pipe, when iron pipes are used to protect alternate-current mains and service wires, but also as giving material for the application of the equations which were published by J. J. Thomson only a week ago. It is a case in which the influence of eddy currents in screening the interior of the iron is so great that any calculation in which consideration of that influence was omitted would quite fail to give even roughly correct results. The eddy currents are in themselves a source of loss, but indirectly they reduce the total loss by protecting the inner parts of the metal from magnetisation. Were it not for this protection the drop in volts due to hysteresial dissipation alone would be greater than the whole drop that was actually observed.—Yours very truly,

"W. H. Preece, Esq., F.R.S." J. A. EWING.

The point that interested me particularly in this inquiry was the effect which this choking influence would have on retarding telegraphic signals and in deteriorating telephone speaking. In long submarine cables the iron sheathing has apparently no retarding effect on the transmission of signals; and this is due probably to its want of circumferential continuity, but with iron piping the form and the effect are different. Here induction and hysteresis will retard the currents and will increase the sum of opposing effects which limit the rate of working. There is a strong tendency to put wires in iron pipes underground to secure safety from wind and snow; but unfortunately this is done at the expense of effectiveness, long lines of iron piping will probably be death to fast-speed telegraphy. Of course, in telephony iron piping is seriously detrimental to single wire working, but then no one would dream of using any but the metallic-circuit system in any underground system.

There is another point for consideration, and that is, may not wood or earthenware or cement replace iron as a conduit for electrical conductors, and be made equally effective from the mechanical and economical point of view?

ANGLO-AMERICAN TELEGRAPH COMPANY.—This Company notify us that on and after May 1st next, the rate for the transmission of telegrams by their lines "*via* Galveston" to all places in the Argentine Republic, Bolivia, Brazil, Chili, Ecuador, Paraguay, and Peru will be reduced to 6s. 2d. per word.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—At a meeting of the Board of this Company held yesterday (Thursday), it was decided that after placing £15,000 to the reserve fund, and £6,293 to the debenture redemption fund, the Directors would recommend at the forthcoming meeting a dividend of 6s. per share, free of income tax, making, with the interim dividend paid in November last, a distribution of £4 per cent. for the year 1891, carrying forward £4,486 to 1892. The bulk of business transacted shows an increase over the corresponding period, but owing exclusively to the large loss on exchange diminishing the receipts, the dividend is reduced.

AN ELECTRIC TRAVELLING CRANE.

An electrically-driven travelling crane, capable of carrying about 2¼ tons, for loading and discharging large ships, has been built by the Allgemeine Elektricitäts Gesellschaft for the Hamburg harbour quays. It was put in operation in November last, and has continued to work without interruption ever since, in spite of the unpropitious wintry weather.

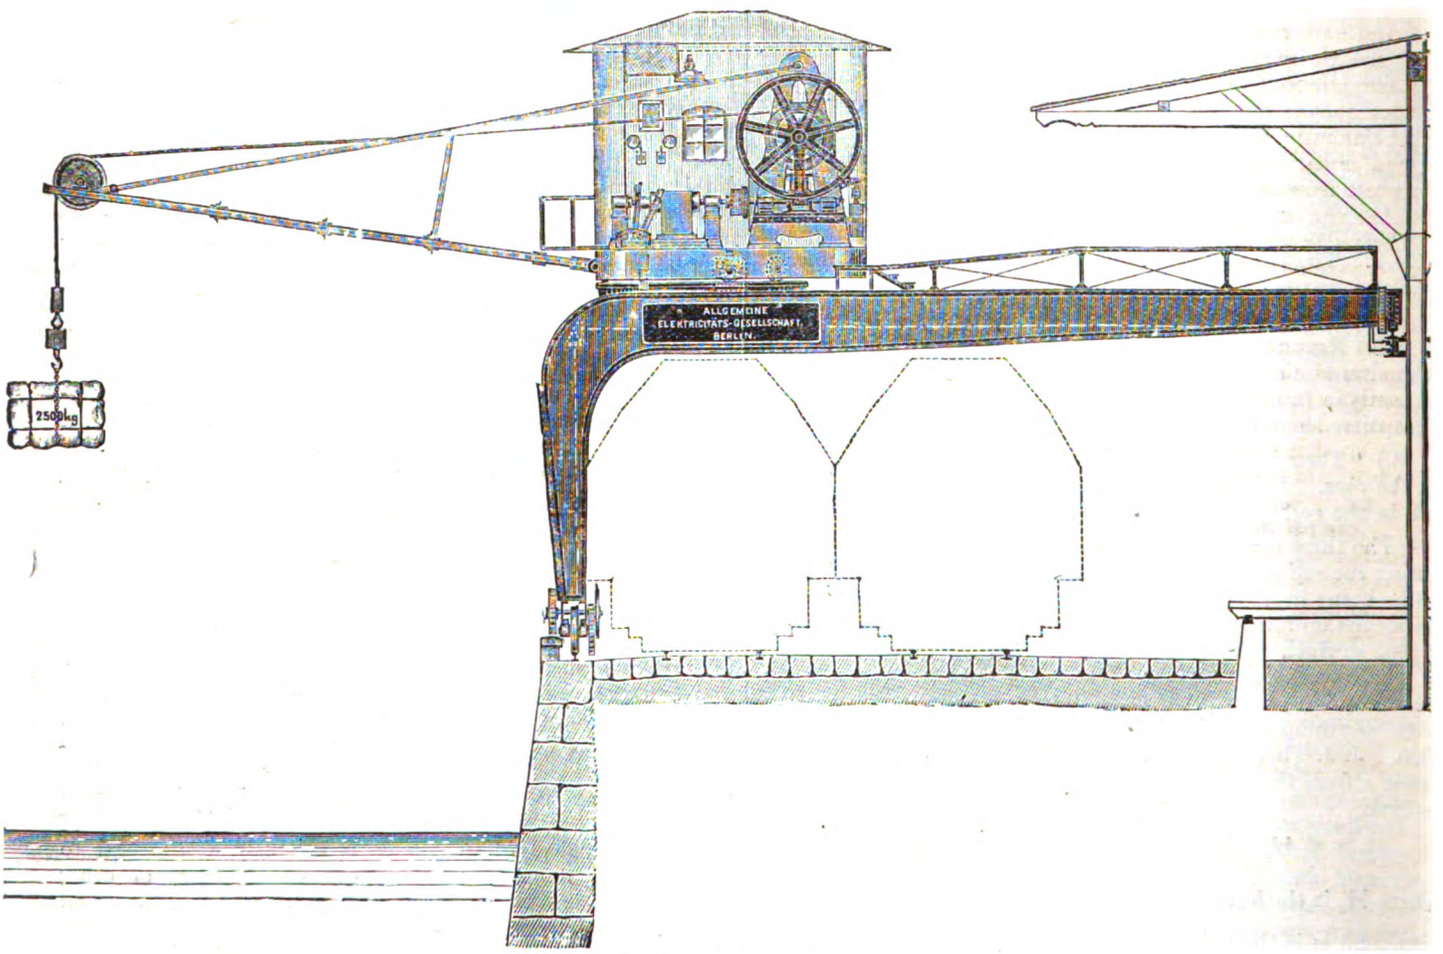
The crane, as shown in the figure, stands upon a traversing framework, which is high and wide enough to permit the passage under it of two lines of railway or waggon traffic, and it terminates alongside a goods shed.

The dimensions and points of its construction are as follows :—

Safe load	2,500 kilog. (nearly 5?cwt.)
Total height of lift	13.75m. (say 45ft.)
Projection of the jib, *i.e.*, distance from the centre of the crane to the centre of the sling hook	10.75m. (35ft. 3in.)
Vertical speed	1m. per sec. (197ft. per min.)
Traversing speed	2m. per sec. (394ft. per min.)

with windows, and mounted upon an iron platform. Each set of these gears is entirely distinct, each having its own electro-motor, and each being controlled by its own particular lever.

The turning of the crane is effected by means of an electro-motor, which drives one of the three guide-wheels under the turntable by worm gear. The worm spindle can be stopped at any moment by a powerful brake actuated by the steering lever when this is in its midway position ; thus the turning motion is controlled with precision. To obviate all liability to damage to the spindles from the swiftly rotating armature, an elastic coupling, a so-called "wire brush coupling" is used, which acts when the brake is applied, permitting the coupled parts to glide past each other and allows the armature to come to rest after a few revolutions. For a similar reason, the above mentioned guide-wheel running on a smooth path was chosen in place of a toothed rail and spur-wheel ; for breakdowns were to be feared with the latter through the rapid turning of the long derrick. There is, however, always a means afforded to the driver of modifying the speed of the crane, inasmuch as the motor is series wound.



2¼-Ton Electric Travelling Crane.

In the construction of the crane it was advisable that wire rope instead of a chain should be used, and in the winding gear spur or bevel wheels had to be avoided for the sake of silent running. The handling of the crane was to be as far as possible like that of hydraulic or steam-power cranes, in which it is possible to raise or lower the load during the traversing of the crane.

The current is brought from the generating station through copper rods carried along the outside of the shed. This station also provides the light for the harbour, and was erected some time ago by the Allgemeine Elektricitäts Gesellschaft ; cables pass through the hollow pivot of the crane and lead to the controlling gear. Around this pivot, which is seated in a turntable, revolves the whole winding and traversing mechanism of the crane, protected by a cabin

The 40 H.P. electro-motor of the hoisting gear is shunt-wound, and connected, like the above, by a "wire-brush coupling" to a worm spindle, which has a powerful brake actuated by the respective controlling lever, as in the former case.

The reversal of the direction of motion is here also attained electrically, viz, by reversing the armature current ; the starting resistance is switched off simultaneously with the movement of the controlling lever, this in its midway position entirely cuts off the current from the motor. By pulling the lever backwards, the current flows first through the field-magnets, then in increasing quantity through the armature, while simultaneously the brake of the worm spindle is released and the load begins to ascend. On the other hand, if the lever is pushed over from the midway position in the forward

Digitized by Google

direction the manipulations are the same; but before the armature receives its current the direction of motion is changed, and the whole hoisting gear now runs the opposite way, so that the load descends. The worm now tends to drive the armature, but the shunt-wound motor does not permit it to force it beyond its normal speed; so then the armature acts as an electric brake, and sends the current back into the conductor instead of consuming energy.

To provide against a dangerously rapid descent of the load in the event of a rupture of the circuit through this brake a second electric brake is furnished, which is equal to any possible contingency. Alongside the hoisting-drum round which the wire rope is coiled, and connected to it, is a brake-wheel, the brake-blocks of which are so weighted that they would be permanently pressed against the brake-disc if there were not on the opposite side a powerful electro-magnet to hold them back, so long as it is influenced by the passage of the main current. Any interruption of the main current makes this electro-magnet inoperative, permits thereby the brake-blocks to fall against the disc, and instantly grips the whole hoisting gear, thus preventing further motion.

The advantages of this electric crane compared with a steam crane are considerable. Firstly, the commercial efficiency of electric motors is, on the whole, higher than that of the steam motors of equal power hitherto employed on the Hamburg quays; and with all other motors the efficiency falls off continuously from various causes, viz., the difficulty of keeping pipe joints, &c., tight. Then, the current used by the electric motors remains always very nearly proportional to the demand of the moment; whereas similar economy is impossible with the direct-action steam cranes hitherto in use, because the principle of expansion is not brought to bear in these. Again, with an electric system having proper insulation, the degree of efficiency may always be calculated beforehand, while considerable losses through long steam pipes, especially in winter, in consequence of the cooling in cylinders and pipes, are unavoidable. Lastly, a properly constructed electric system requires but few repairs, and repairs form a big item with steam cranes.

Now that the crane has been working without a hitch during over four of the least propitious months of the year, and has consequently been taken over by the dock authorities, not only may the *raison d'être* of electric cranes be said to have been established, but the realisation of this first attempt must be accepted as evidence of the foresight of the Hamburg harbour authorities, and its prompt and complete success as proof of the skilful design and construction on the part of the Allgemeine Elektricitäts Gesellschaft, whose London representatives are the Keys' Electric Company.

NOTES ON THE LIGHT OF THE ELECTRIC ARC.*

BY ALEXANDER PELHAM TROTTER, B.A.

It is apparent to intelligent observers, and well known to all electric light engineers, that the light of an arc lamp is not emitted uniformly in all directions. Photometrical measurements of arcs are generally expressed by a polar curve, the length of the radius vector representing the candle-power. Although a good deal of work has been spent on this subject, the real meaning of the shape of these curves has not attracted much attention. They all exhibit the same characteristics, and it is easy to notice two distinct types of variation. One variation is found with arcs employing a large current, and consists in the emission of a small quantity of light in a direction above the horizon, the curve rising a little above the horizontal axis. Another type of variation is the narrowing of the whole curve, and the concentration of a large proportion of the light at an angle of about 40deg. or 50deg. with the vertical.

A rather complicated treatment of the subject has been made by M. Rousseaut† with the object of finding a formula for the distribution of the light. His treatment appears to be empirical, and having arrived at a formula he does not appear to have recognised the practical meaning which it contains.

It has been assumed by many persons that the hollowing of the crater of the positive carbon tends in some unexplained manner to concentrate and throw the light downwards. It is evident that the lower or negative carbon intercepts a good deal of the light, but there speculation appears to have stopped. A little consideration will show that the effect is precisely and identically the same as though the end of the positive carbon were flat. No tilting of an incandescent or other luminous surface can make it brighter, and, on the other hand, if it is covered with a thin imperfectly transparent layer, as in the case of the atmosphere of the sun, the edge will appear less bright than the middle of the disc. The quantity of light emitted by an incandescent disc in any direction is proportional to the amount of surface visible from that direction. That is to say, candle-power varies then as the cosine of the inclination.

Cosines plotted as a polar curve give a circle passing through the pole. This theorem is not to be found in mathematical works, being much too easy and simple for those students who have got so far as polar curves. The candle-power of the crater of an arc lamp should then, if plotted as a polar curve, coincide with part of a circle. Any deviation from the circle must have some cause. Two such deviations are observed, and their causes are easily recognised.

An ideal continuous-current arc, in fact any good one with first-rate carbons, has a uniform horizontal crater, and this gives no light in a horizontal direction, though a little may come from the hot sides of the carbon, especially if it is carrying a rather large current. No brightly incandescent surface is seen. The pointed negative carbon is seen in profile, and some light is emitted by it. From what Prof. S. P. Thompson and others have told us of the physics of the arc, it is very probable that the seat of the dissipation of energy is primarily at the surface of the crater. The negative carbon only becomes hot by being cooked in front of the crater. It is wasted, probably, by mere combustion; and even this waste is reduced by the deposition, under some circumstances, of carbon transferred from the positive pole. The waste of the positive carbon is undoubtedly due to volatilisation. Prof. J. J. Thomson and others have shown that electrolysis is not necessarily confined to bodies in the liquid state, and it seems probable that the volatilisation of carbon at the crater and its deposition, under certain conditions on the negative carbon, is closely allied to electrolysis, the positive pole behaving as an anode, both in its wasting and in the fall of volts at its surface. The absorption of energy appears to be twofold. A certain quantity of heat is required to produce the change of state from solid to vapour, and a certain difference of potential must be required to produce the electrolysis. In one of the very interesting articles by M. Palaz,* in which he abstracts and compiles the work of numerous Continental writers, he states, without giving his authority, that 85 per cent. of the light of an arc is emitted by the positive carbon, 10 per cent. by the negative carbon, and 5 per cent. by the flame of the arc. It seems probable that in most cases the proportion of light emitted by the positive carbon is even greater than this. The word "arc" will be used in this Paper as an abbreviation for arc lamp, and will not be used to denote the flame which plays between the carbons. The word "crater" will be used to denote that portion of the positive carbon which is at the highest degree of incandescence. This portion is generally well defined, the colour being uniform. The word "crater" will not be used to signify a hollowing of the carbon.

During the Antwerp Exhibition in 1885, M. Wybauw† made a number of photometric measurements of arcs by different makers. The full curve in Fig. 1 represents the mean of a large number of observations made, no less than 26 different arcs having been tested. The cosine of 60deg., being one-half the area of the crater seen from this direction, is one-half of that of the full circle; the candle-power is one-half of that emitted by the crater; and the length of the radius vector corresponding to 60deg. may be taken as the radius of the circle. The light due to the negative carbon is clearly shown as an excess above the circular curve; there is, indeed, nothing else to which it can be due, except the red-hot walls of the crater.

At about 60deg. the curve of candle-power begins to fall off, and this is due to nothing else than the shadow of the lower carbon, which intercepts more and more of the light as we pass to smaller angles, until, if the carbons be of the same diameter, no light is thrown in a vertical direction.

In considering the real meaning of the latter part of the curve, the author drew a number of views of a pair of imaginary carbons, projected at different angles. The elliptical area of the crater in each view was calculated, and he found that these areas, plotted as radii of a polar curve, gave a curve closely resembling the well-known candle-power curve of the arc. It follows that if this be proved to be true by experiment, the candle-power per square millimetre of the crater is constant.

The author communicated this result to Prof. S. P. Thompson, and asked if he would see whether actual experiment would confirm it.

A series of very interesting experiments has been carried out at Finsbury Technical College by Mr. C. F. Higgins, senior student. A "Planet" lamp, taking 8 or 9 amperes, was first employed, and the first experiments showed that the light was undoubtedly proportional to the area of the crater. In order to carry out the

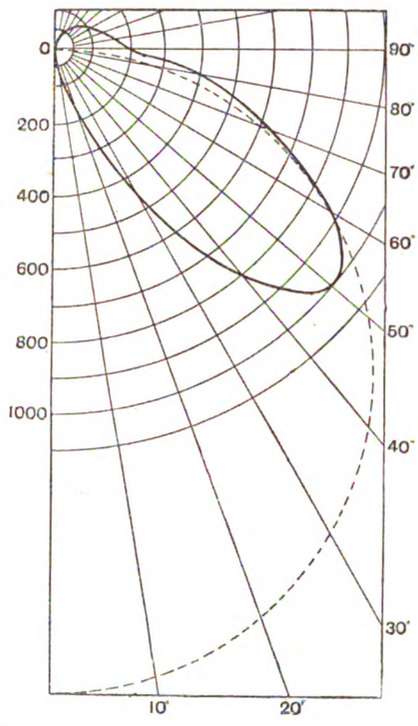

FIG. 1.

experiments with greater accuracy a larger lamp was required, and Messrs. Johnson and Phillips kindly lent a Brockie-Pell lamp, taking 25 amperes. The following apparatus (Fig. 2) was constructed by Mr. Higgins at the workshops of Finsbury College, for the purpose of projecting an image of the arc :—

An arm adjustable on a horizontal axis, and provided with a clamping nut and graduated arc, carries a lens and a mirror set at an angle of 45deg., with the direction of the ray of light falling

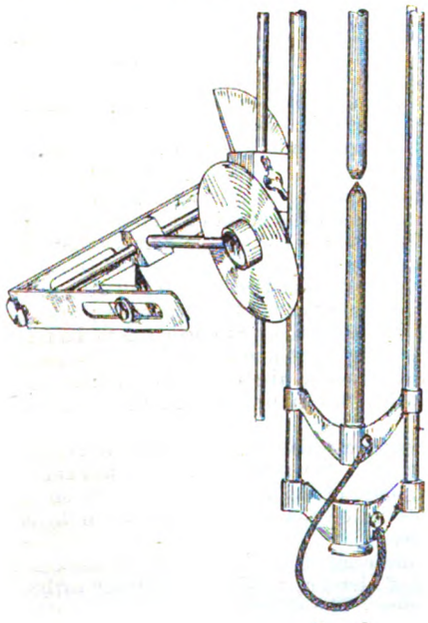

FIG. 2.

on it, and reflecting the ray in a direction parallel with the axis of the radial arm. An image of the arc may thus be projected on a screen. As the radial arm is moved the image turns round, but this does not interfere with the observations. An Ayrton-Perry photometer, slightly modified, was used to measure the light with a standard candle, and this was done by removing the projecting lens, and allowing the reflected beam to fall on the mirror of the photometer. When the lens was replaced for the purpose of projecting the image, the mirror of the photometer was removed, the rest of the photometer remaining undisturbed. The image was received on a sheet of drawing paper and was amplified about 14 times. The outline of the incandescent crater was traced in pencil, and in some cases an outline of the carbons was drawn.

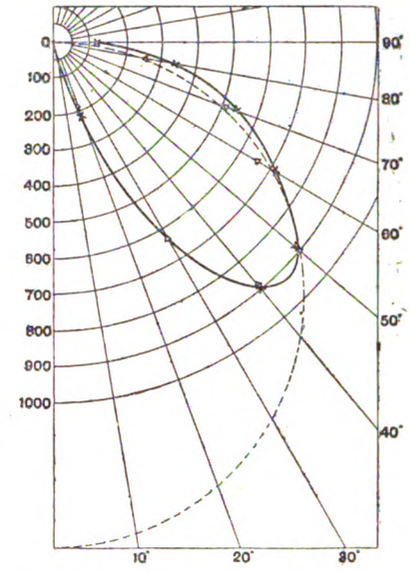

FIG. 3.—Curve of areas of crater and candle-power of normal arc. Δ = area and × = candle-power. The scale of radii is arbitrary.

The diameter of the carbons formed a standard for absolute measurements. Readings were taken at every 10deg. inclination. The area of the tracings was measured by a planimeter.

In the first experiments the absorption of the two mirrors of the photometer was neglected, and the results are not, therefore, to be taken as candle-power. The mirror on the radial arm was of platinised glass, since an ordinary mirror gave a double image. The reflecting power was not good, though the image was clear. The areas were also measured to an arbitrary scale at first. Figs. 3 and 4 give polar curves of two sets of observations. The photometer readings are represented by circles, and the areas by triangles. A general coincidence of both sets of observations with the well-known curve is evident. Figs. 5 and 6 are reproductions of the tracings.

It is rather difficult, in many cases, to estimate the relation between two polar curves by mere inspection, partly perhaps

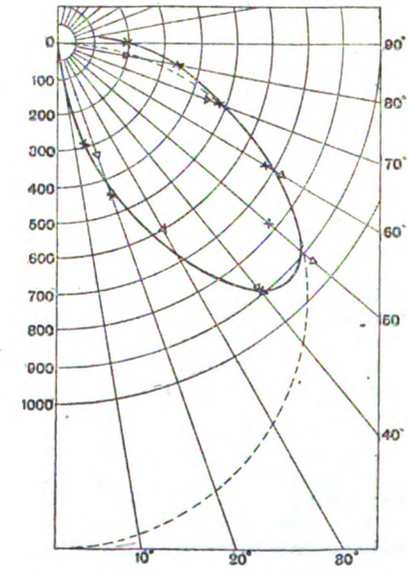

FIG. 4.—Curve of areas of crater and candle-power of short arc. Δ = area, and × = candle-power. The scale of radii is arbitrary.

because they are so seldom used in practice. Two different curves may be drawn, the one through the photometer readings, and the other through the areas of crater ; but, owing to the difficulty of arriving at accurate results, on account of changes in the length of the arc, which greatly affect the inner part of the polar curve, and the occasional indistinctness of outline of the crater, the errors of either set of readings are probably as great as their departure from the curve drawn freely among the two sets.

Digitized by Google

Useful as it is to plot as a polar curve observations which relate to measurements taken at different angular directions, the relation between the two sets of readings may be examined more easily when they are plotted with rectangular co-ordinates. (Fig. 7).

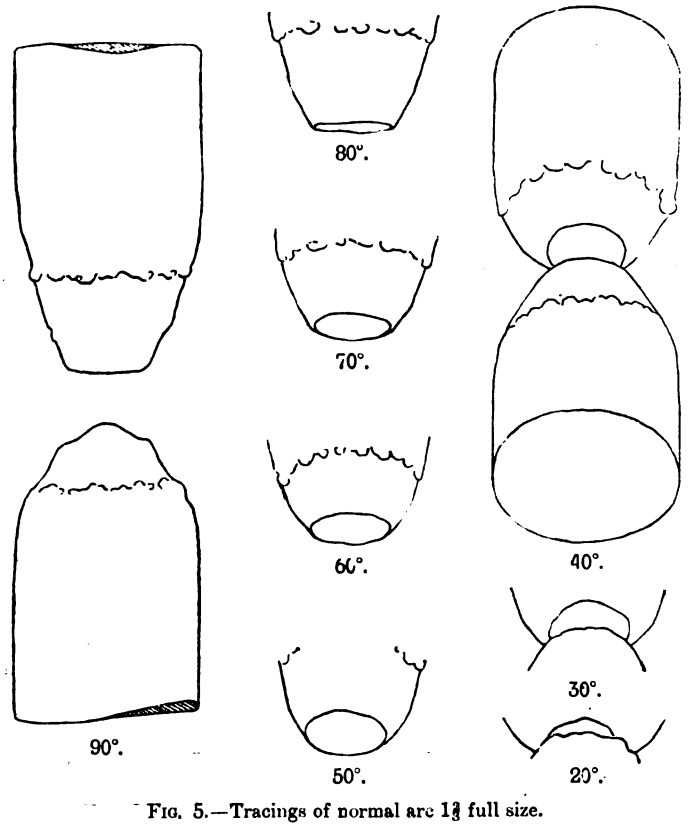

Fig. 5.—Tracings of normal arc 1⅜ full size.

A straight line cutting the axis at 100 c.-p. seems to fit the results. This may be explained by the light which is emitted by the red-hot and glowing parts of the carbon. These were not included in the measurement of areas, the true crater only was measured. The

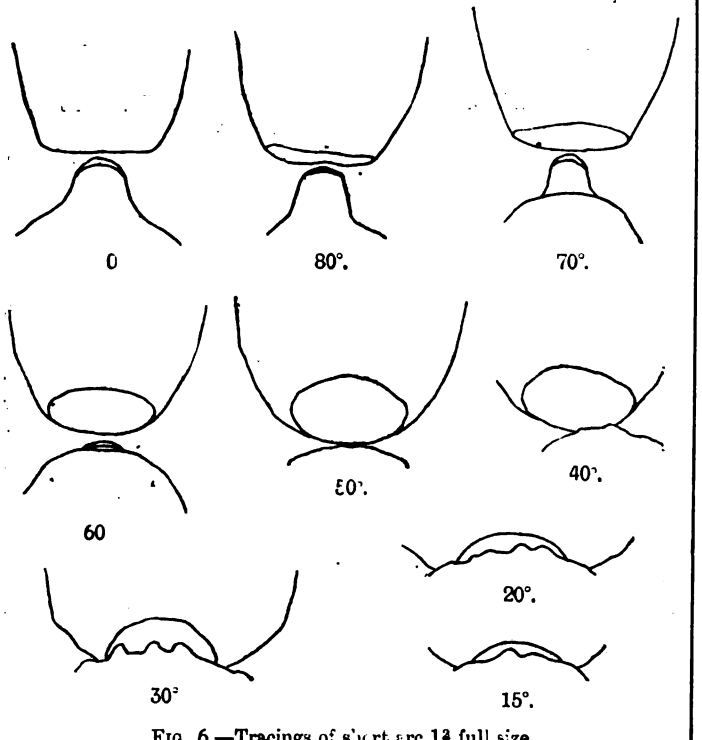

Fig. 6.—Tracings of short arc 1⅜ full size.

author has been unable to carry out any complete experiments on the photometry of arcs, the present Paper is only a collection of notes on the subject, which is treated qualitatively and not quantitatively. The measurements, for various reasons, were relative, and attempts were made on one occasion only to take direct readings in candle-power. The image of the crater at 60deg. was projected and traced, and measured by a planimeter. The mean of several fairly concordant readings was 20·8 sq. in. The diameter of the image of the carbon was 17in. Its actual diameter was 0·6in. The image was therefore magnified 28·3 times. The real area of the crater was 0·025 sq in. The candle-power readings were taken at the same angle, and immediately after the tracing of the image in each case, being measured directly from the arc without reflection. They were fairly concordant, and gave a mean of 1,065 candles. At the maximum position (about 45deg.) this

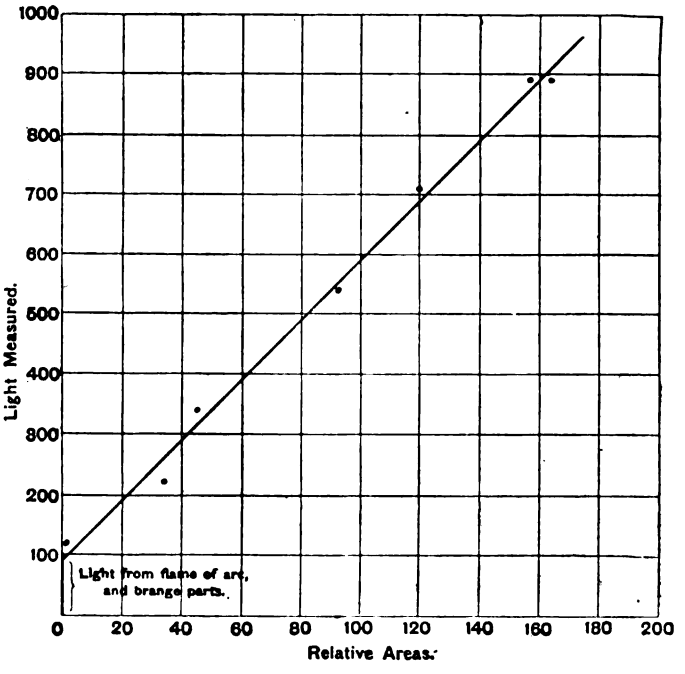

Fig. 7.—Areas of crater, and light of normal arc.

would give about 1,400 candles. It follows, therefore, that the crater gave 42,600 c.p. per square inch, or 64 c.p. per square millimetre. The amperes were 26, and volts 51.

It is as impossible to raise carbon above the degree of incandescence of the crater of the arc as it is to raise water above boiling point or ice above melting point.* No substance has yet been suggested for "improving" arc-lamp carbons, which is less volatile than carbon. Even the core of cored carbons, while it serves a very useful purpose in steadying the arc, is less brilliant than the rest of the crater. If a lower temperature than the normal incandescence be found at the crater, it is because the positive carbon is too large for the current. Under these circumstances the arc generally flickers irregularly, and a highly-incandescent patch travels about over the surface of the crater.

The large amount of light intercepted by the negative carbon raises the question: What becomes of it? It is evident that it strikes the lower carbon, and is probably converted into heat; but since only about 10 per cent, of the whole radiation of an arc is in the form of light,† most of the "cooking" of the lower carbon is done by mere heat.

It is not difficult to reconstruct the shape of the carbons, which must have given rise to the curve given in Fig. 1, but to do so is nothing more than a geometrical exercise, and leads to no useful result. A similar relation obtains between the candle-power-curve of an alternating-current arc and the shape of its carbons, but the use of alternating arcs is not common; the light is not, for outdoor purposes, thrown in a useful direction, it is difficult to prevent the arc from flickering round the carbons, and they give so much trouble from other causes that they are seldom worth using.

THE PRACTICAL OPERATION OF THE GEARLESS MOTOR.*

BY S. H. SHORT.

At first thought it does not seem necessary to place on the market a motor of new design which involves the abandonment of gear wheels for transmitting the power of the armature to the axle; but when we consider it carefully, and examine all the advantages to be gained by so doing, we feel justified. While the single reduction type of motor is undoubtedly eminently successful, I believe we can go a step further with great advantage, that we can connect the armature directly to the axle of the car, without the intervention of armature, intermediate or other kind of gears. The abandonment of gears, or a "gearless" motor, is undoubtedly absolutely necessary where high speed is required for driving trains of cars upon suburban or interurban lines—a thing which we shall undoubtedly be called upon to do within the near future.

Those of you who have operated electric street car lines can appreciate what a serious thing it is for a tooth to break out of a gear in a car motor while it is in service. Again, it is a great source of loss to a street railway company when it is necessary to take a car out of service to replace worn-out gear wheels. A car earns on an average in a good street car city about $20 per day. If the car is taken off the road for half a day or a day, we not only lose the cost of the repairs, but we lose the profits on the day's run. The causes which disable cars should be reduced to the minimum, and it is to this end that we are advocating the use of no gears in a street car motor. It is very seldom now that we have trouble with armature bobbins and field-magnet spools burning out. While we had some difficulty of this kind in the early days, we have learned how to insulate and protect the motors for street car service, so that electrically they are quite equal to the work they are required to do. We have, therefore, to look more carefully to the mechanical construction of a street car motor, and perfect that part of the machine.

We will now take up the matter of the power lost in spur gearing, and see what we can gain in that direction by abandoning gears. When we first took up the subject of a gearless motor, we set about to see how much could be gained in the efficiency of transmission of power by doing away with the gears. I made a very careful and thorough investigation of the losses between the armature pinion and the intermediate gear, and between the intermediate pinion and the axle gear, of a double reduction motor. I first put a double reduction motor in good order, eliminating the armature bearing losses as much as possible, by running the motor for a long time, to wear the bearings down to a good surface. I put my power brake for determining the H.P. directly on the armature shaft, and ran my motor, delivering different H.P.'s all the way from no H.P. to its full output—20 H.P. At the same time we measured the E.H.P. which was being put into the motor, and from this we constructed a curve of efficiency of the motor at different loads, which curve is reproduced as the upper curve in Fig. 1. The greatest efficiency reached by this motor was about 70 per cent. at a load of from 14 to 16 H.P. The efficiency at small loads, say at 2 H.P., was something like 50 per cent. at 4 or 5 H.P. an efficiency of 65 to 70 per cent.

We then took the brake from the armature shaft and replaced it with a well-made armature pinion, allowing it to mesh with a well-made intermediate gear, these gears being cut as nicely and as carefully as possible, so that there would be the least possible loss between the two in making this test. Putting the brake on the other end of the intermediate shaft we again secured the number of readings of the H.P delivered, after being passed through this one pair of gears, the E.H.P. being indicated carefully at the same time. From the efficiency at different H.P.'s thus obtained we produced a second curve, which is shown in Fig. 1 as the middle curve on the diagram, and we find that the efficiency of this arrangement has fallen considerably. We once more removed the brake and placed the intermediate pinion on the intermediate shaft, allowing it to mesh with the axle gear. The brake was now placed on the axle itself, and another set of measurements—the same as those before made—were secured, and a curve of efficiency again plotted, which showed a large loss in these gears, the efficiency at the axle being less than that at the armature by an amount indicated by the two outer curves. The results showed that at 14 H.P. delivered by the motor we obtained an efficiency of 70 per cent. as a maximum when the brake was placed on the armature shaft. When the brake was placed on the intermediate shaft delivering 14 H.P. the efficiency dropped to about 62 per cent. When placed on the axle, the efficiency dropped to a little less than 55 per cent., showing a loss in the gears of some 15 per cent., when delivering at 14 H.P. You will find in going over these curves that the loads vary considerably with the speed. Making an efficiency curve of the gears alone at different speeds, you will find the efficiency is very low at heavy loads and slow speeds, and rises to its highest at medium speeds and medium loads. It again falls when running up to higher speeds. For this reason it is more economical to run a geared motor not too fast or too slow, but at a medium speed. This fact has been established long since in the use of gears in other classes of machinery, and in designing machines where power must be transmitted through gears the best possible speed at which gears are to be run and the relation between pinion and gear are carefully considered. In the single reduction motor we regain, we might say, more than half of this loss in efficiency, because the gears are run at a moderate speed. I think that this one feature of gear loss makes it desirable to abandon their use in street car motors if possible. If we can save in practice 15 or more nearly 20 per cent. of the power consumed in operating a street car motor, by using the gearless instead of the double reduction type, it is well worth while, as this means the consumption of less coal and the reduction of first cost in the power plant and accessories.

Another set of curves was developed in the same way as those shown in Fig. 1, three motors being used in the test—the double reduction, single reduction, and the gearless. From these curves* it was seen that the efficiency of the gearless motor at the axle, when delivering 14 H.P., reached very nearly 70 per cent., or very nearly the same efficiency as the double-reduction motor at the armature shaft. The single-reduction motor, when delivering the same power through one pair of gears, showed an efficiency of 60 per cent., while the double-reduction showed a little over 50 per cent. These practical tests show that with the gearless motor we actually save from 15 to 20 per cent. in the power it is necessary to put into the car in order to get the same result at the axle.

We will now give you a description of the construction of our gearless motor. Gearless motors have heretofore, as you well know, been constructed and operated. The armature has been placed directly on the axle, and fairly good results have been

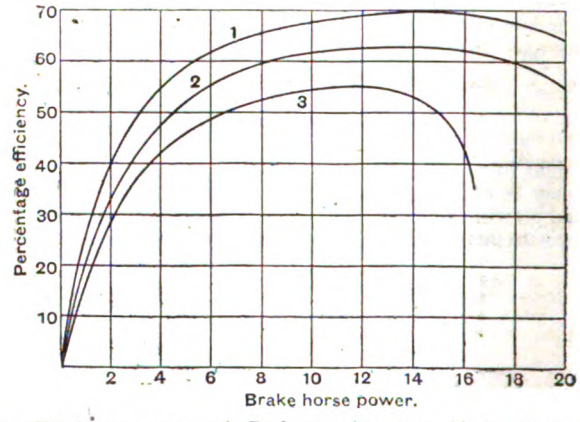

FIG. 1.—Efficiency curves. 1. Brake on Armature Shaft; 2. Brake on Intermediate Shaft; 3. Brake on Axle Shaft.

obtained. The City and South London Railway in London is operating its road with gearless motors to-day. These motors are high speed, making the problem somewhat easier. It is, however, difficult to construct a small motor, not too large to be placed under an ordinary street car, the speed of which shall not be above 105 to 150 revolutions per minute. Because of the light construction of the road-bed in street railways it is also necessary to avoid the heavy hammer blow which occurs at the rail joints from a motor partly or entirely carried on the axle. When the wheel of the car passes from one rail to another it falls, striking a very heavy blow. If we have a weight directly attached and carried on the axle, without any intervening cushion or spring, we will have a very severe sledge-hammer blow on the rail at every joint. This will soon pound out and destroy the rails.

You are all familiar with the difficulty which is experienced in keeping up the rail joints on an electric line. The reason for this is apparent, if we think a moment, as it is a new element which has made its appearance since the introduction of the electric motor. All geared motors are supported at one end directly on the axle, by means of axle bearings. At the other end these motors are supported on springs; thus one-half the weight of a geared motor is carried directly to the car axle without the intervention of any flexible material. The actual weight carried by a set of wheels on the rails does not seem to affect the joints materially. Old horse cars even when carrying heavy loads of passengers, did not affect materially the rail joints. Cable cars do not destroy their tracks, no matter how great their loads. Therefore it must be that this heavy weight of the motor carried solidly on the axle is the thing that is breaking down the rail joints on electric lines.

* Abstract of a Paper read before the Chicago Electric Club.

* These curves being, of course, practically identical with those of Fig. 1, it has not been thought necessary to reproduce them.—ED. *E.*

This heavy jarring also crystallizes the axles, and we have complaints from all over the country that axles on motor cars are breaking. When we come to examine these breaks we find that the iron has crystallized, and the manufacturers are now endeavouring to overcome this by increasing the size of the axles. With the gearless motor, as we now construct it, none of the weight is directly carried on the axle. The armature is mounted on a hollow shaft which surrounds the axle, leaving an air space of about an inch entirely around the axle. This hollow shaft is really the armature shaft of the motor, and is carried in its own independent bearings in the motor frame. The motor frame consists of a box made in two halves. These two halves are fastened together, and contain the field-magnets and enclose the whole, protecting it from mud and dust, the only opening in the box being on the upper side next to the car floor. This box, which makes the complete motor when assembled, is provided with three projections at right angles to the armature shaft. These projections are made to receive steel spiral springs, similar to car springs. These springs are supported on the cross girders of an ordinary truck, such as is commonly used for motor cars, and support the entire weight of the motor. The axle is passed through this hollow armature shaft, and can move freely in any direction within it. At one end of the hollow armature shaft is placed the flexible driving device which communicates the motion of the armature directly to the axle. The axle has a free end play of 2in. through the motor and armature shaft. This is necessary in rounding curves and to ensure freedom for the movements of the truck.

When the wheels drop from the end of one rail to another the motor does not immediately follow, its inertia being so great. The wheels not being very heavy, do not make a heavy blow, but by the time they have reached another portion of the rail the motor falls down against its springs, distributing, as it were, the blow over a considerable length of the rail, thereby preventing serious damage to the rail joint.

Gearless Motor Trial—Aug. 17, 1891—in Regular Service pulling Trail Car—Temperature equals 96° F.

It is contended that in a geared motor we have an enormous leverage through the gears. If we had a small armature, the same as is used in the geared motors on the axle, we should not, of course, be able to start the car, or to do the work necessary in moving a loaded car; but we have a large armature placed in a very strong magnetic field, and we have a great many more turns of the same current around the armature, thereby gaining a greater leverage, because of a larger diameter of armature and a greater pull at the end of that lever. Air resistance we are liable to, the greater loss in the dead resistance of the motor, but by designing our motor with a very low resistance magnetic circuit we are able to cut down the wire on the machine so that its resistance is quite low, being only about 2½ ohms. There is another advantage in this low-speed motor, which is not small; the wear on the commutator is very light, and the heat produced by the friction of the brushes on the commutator is exceedingly small, making the motor run cool in all its parts. We are obliged, of course, to take advantage of everything that is possible in the construction of the gearless motor, in order to make it small and light enough for street car service. We use the best wrought iron and steel in its construction, because of their superior magnetic qualities. We have to use the best copper of highest conductivity to reduce our resistance losses. This, of course, is in the end an advantage to the machine, because it makes it stronger and less liable to breakage.

To answer the question as to how much current is taken by the gearless motor in operating a car, we have prepared a copy of readings taken from a car in actual service, drawing a trail car. The current readings, also the pressure readings, were taken every half minute, and from the table a very good idea of the amount of current required can be gained. These readings were taken in August on the East Cleveland Railroad, Cleveland, O. On this road the traffic is very heavy, although the grades are light. We have carefully tested double reduction, single reduction, and gearless cars running on the same track on roads in Cleveland, O., taking at the same time readings of current and pressure, and we have found that in some cases the single reduction would require

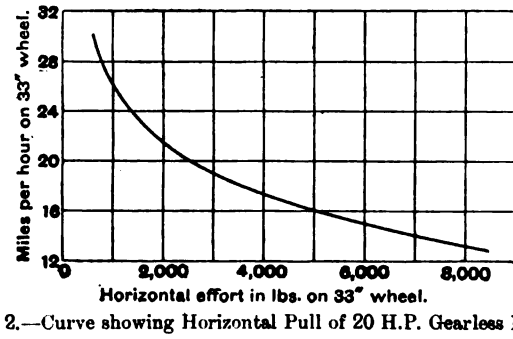

FIG. 2.—Curve showing Horizontal Pull of 20 H.P. Gearless Motor.

the least amount of current, sometimes the double reduction and sometimes the gearless, depending upon the number of passengers hauled, stops made, and other things that might come in to consume more or less power; so it is difficult for us to say that there is any difference in actual power consumption between the three classes of machines.

The gearless motor is capable of starting loads as quickly as the geared motor, and is capable of starting as heavy a load under similar conditions, and we have a curve shown in Fig. 2 which illustrates the actual horizontal pull of a 20-H.P. gearless motor, mounted on 33in. wheels. In examining this curve it will be seen that the horizontal effort in pounds when the car is running 20 miles per hour is about 250. In ordinary street car practice we find that it requires about 20lb. per ton to move a load on street car rails. This means that with a horizontal pull of 250lb. this single motor could move a car weighing 12 tons at the rate of 20 miles per hour, or, as the curve will show, that at 14 miles per hour the motor has a horizontal pull of 700lb., or it will move a load of 35 tons at the rate of 14 miles per hour on a level track. This curve is not falling off rapidly, certainly not as rapidly as it would with a geared motor, because the loss in the gears begins to increase very rapidly with the heavy loads. You can easily figure from this curve what the motor will do under any conditions of load, grade, and speed. The tendency in street-car practice is to increase the speed of the cars; and the gearless motor lends itself especially to this end, as we have found that with very rapid speed geared motors wear out the running parts more rapidly, and become very much more expensive to maintain. While the gearless motor can operate with as great economy at the slow pace required in crowded streets it is also capable of running at a very much higher speed in suburban traffic without the slightest fear of damage to the machine. In this respect it makes a very much more flexible motor than the geared machines. You can easily understand that this motor now makes

Digitized by Google

it possible for us to develop large electric locomotives to be used in elevated railway service, and for pulling suburban trains in and out of large cities. From calculations and designs which we have made, we find that the size and weight of the motors required for 200 and 400 H.P. locomotives is not more than is necessary to produce the required adhesion to the rails needed for the required tractive pull to move these heavy trains. The motors are not large comparatively, and their economy will be very great. We believe that this branch of electric railroading will develop rapidly, and that within a few years gearless electric railway motors will be used in places, for purposes, and in numbers unthought of at the present time.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.—TUESDAY, APRIL 26TH.

Coast Communications.

Sir E. BIRKBECK rose to move the following resolution standing on the paper in his name: "That, with a view to the better prevention of loss of life and property in cases of vessels in distress or shipwrecked on the coast of the United Kingdom, and to give the earliest possible information to lifeboat authorities and rocket-apparatus stations, in the opinion of this House it is desirable that all coast-guard stations on the sea coast and signal stations should be telephonically and telegraphically connected by Government, and that on those parts of the coast where such stations do not exist, the post-offices nearest to the lifeboat stations be telephonically or telegraphically connected; and that a Royal Commission be appointed to inquire into the desirability of connecting certain light-vessels and rock lighthouses by cable with the mainland in order to give information of vessels in distress."

It would be a matter of general surprise that Great Britain was so behindhand in the adoption of means for the better preservation of life and property at sea. The responsibility for this question of loss of life had been shunted from one Government department to another. Great Britain was in the unfortunate and humiliating position of having to admit to the world that Denmark, with her import and export trade of only 30 millions, had carried out successfully a system of coast communication, while she herself had done nothing, though her import and export trade amounted to 743 millions.

In the resolution he had divided the question into two parts. The first referred to coast communication proper, and the second to communication by cable with the floating light-vessels and rock lighthouses. As experiments had been carried out with reference to the latter subject, he would deal with that first. Communication with the outlying light-vessels and rock lighthouses involved serious engineering and financial questions; and, therefore, it ought to be considered in the first instance by a Royal Commission. The practicability of this communication had been absolutely proved; and cable communication with the Sunk light-vessel, off the Essex coast, was established in December, 1884. In 1887 the then President of the Board of Trade appointed a Departmental Committee to inquire into the advisability of continuing cable communication with the Sunk lightship. He himself served on the Committee, and, together with Colonel King-Harman, found himself in a helpless minority. He was obliged to draw up a minority report because the Committee decided that the maintenance of the communication was not desirable, it having involved considerable expense and produced but little result in the saving of life. He had never regretted his action in that matter. He strongly declared his opinion at the time that the experiment ought to have been carried out for a further five years, and that Parliament ought to have voted a further sum for experiments. During the trials that were made, there were no bad gales, and exceptionally few cases of disaster on the neighbouring sands. The Trinity Corporation were adverse to the experiment because they thought the money might be better spent; and they were particularly influenced by one fact which was brought out in evidence. On one occasion the lightship was hailed by a passing vessel, the master of which, a newly-married man, desired that a private message should be delivered to his wife on shore. It was, however, clearly proved that the officers of these lightships were perfectly capable of undertaking the entire duty of working cable communication. In case of snowstorms or fogs, when rockets could not be seen from the mainland, the officer in charge of a light-vessel could tell the exact position of any ship in distress, and thus serious delay in sending aid was avoided. He quoted extracts from telephonic messages which had been received on the mainland through the Sunk cable, in which the exact position of the vessels in distress was clearly described, and called attention to several cases in which the existence of coast communication would in all probability have prevented serious loss of life.

The question as to which light-vessels and rock lighthouses ought to be placed in telegraphic communication with the mainland was a matter for inquiry by a Royal Commission. The Fastnet, the Tusker, the Eddystone, and other rock-lighthouses were undoubtedly all points of very great importance; and as regarded the Fastnet, where the communication had been broken, the evidence given before the Departmental Committee of the Board of Trade proved that there was no difficulty whatever, from an engineering point of view, in carrying out this proposal.

He had taken up the question of coast communication proper on behalf of the lifeboat service and the rocket apparatus service, because it had too often occurred that when the lifeboat or rocket apparatus got to the spot where a wreck had taken place they found only pieces of the wreck left, and possibly the dead bodies of the crew. There had been instances in which as many as six lifeboats had gone out to one case of distress, when, if there had been cable communication, it was probable that only one lifeboat need have gone out. Then it was necessary to consider the case of a steamer or vessel passing a headland and being sighted from the lighthouse where men could see that she was being driven before the wind and was approaching too near the shore. It might then be too late to get out the adjacent lifeboat, because the vessel would be driven too far for the lifeboat to reach her in time; but if there were another station 10 miles off a telegram or telephonic message would secure the launching of the lifeboat there or the sending of tugs to assist the vessel in distress. This winter off Lundy Island a steamer ran aground in a snow storm on a Friday morning, and the fact was not known on the mainland till Sunday, but in the interval those on the steamer had been rescued by the throwing of lines. Still, the fact remained, and it was important from a commercial point of view, that there was no communication with the mainland between Friday morning and Sunday.

The members of the House who represented the naval service would admit the importance of this question to the Navy. The Duke of Edinburgh, on terminating his command of the Naval Reserve, wrote an important despatch, calling attention to the absolute necessity of having communication between all the coastguard stations on the coasts of the United Kingdom. The present First Lord of the Admiralty had added upwards of 100 stations to the 50 that were in existence before; but, although the Admiralty could boast of 160 stations which were now in telegraphic communication, the fact must be realised that it was only during the naval manœuvres that the communication was open all night and all Sunday; during the remainder of the year the communication was open only between 8 a.m. and 8 p.m. and for two hours on Sundays. It would be remembered that one of Her Majesty's ships coming from Ireland to Plymouth, and being caught in a gale of wind, took refuge under Lundy Island, and as no intelligence was received of her whereabouts, vessels were ordered out from Plymouth in search of her. This action, and the anxiety out of which it arose, would have been avoided if there had been communication between Lundy Island and the main land. Whether it was for the saving of life and property, for the promotion of shipping and commercial interests, for facilitating naval movements, or for assisting our fishing industry, coast communication was all important.

Denmark had set a bright example. On the coasts of America the facilities of communication had been the means of saving many lives. All the lighthouses of Holland were connected with the mainland by wire. The Cape of Good Hope had five lighthouses with telegraphic communication. The Indian Government had carried out this policy, and many other countries had done so. He could quote cases in which most disastrous loss of life had occurred round our coasts where the calamity would have been avoided, or greatly mitigated, had telephonic communication existed. The superintendent at Lloyd's gave evidence before the Board of Trade Committee in 1887 to the effect that there was a number of their signal stations that had been the means of saving life. The Deputy Master of the Trinity Corporation, Sir S. Webb, in giving evidence before a committee of the Lifeboat Institution, gave it as his opinion that there was no reason whatever, where a lighthouse was situated at any point where it was likely to give intelligence of a vessel being in distress, why one of the hands belonging to the lighthouse should not immediately telephone the fact to the nearest post station, whence it could be communicated to the nearest lifeboat station. In order, however, to make coast communication effective, it was absolutely necessary that telegraph offices should be open during the whole 24 hours every day of the week, Sunday included. The system ought to be as effective as the fire-escape system of the metropolis was. The evidence was overwhelming as to the necessity of coast communications; and whether it cost £50,000 or even £200,000 to set them up, that was a minor matter in comparison with the better preservation of life and property at sea. The British sailor looked to the House of Commons to provide further means for the safety of life. He knew the fishing industry looked forward with great interest to what the House of Commons was going to do with regard to this matter The commercial community regarded the question as one of very great importance. Over 60 Chambers of Commerce had passed resolutions in favour of coast communications being carried out. He had not heard of one person, whether in the House or out of it, who had ever said a word against it, and therefore he hoped the House would come to a unanimous resolution in favour of the motion. He appealed to the House of Commons, by accepting the resolution, to put an end to the degrading position this country had so long occupied in connection with this matter. He begged to move the resolution which stood in his name.

Mr. MARJORIBANKS, in seconding the resolution, said they ought to be quite as prompt in providing for the protection of life and property from the winds and waves as they were in providing protection from fire.

Sir J. FERGUSSON remarked that it would be easy to exaggerate the good that could be done by connecting every coastguard station with the telegraph. Recognising, however, the necessity of communication with exposed parts of the coast, they had at some labour framed an estimate of the cost necessary to give telephonic communication with the coastguard stations from the Isle of Wight to Lynmouth in North Devon. That covered a considerable portion of coast to which attention had been called of late years, and included connections with outlying islands, such as Scilly. The estimate for this was over £16,000. The work of framing estimates for communication all round the coast would be continued. The fact that the matter was in the hands of the Post Office showed that it had gone beyond the stage of contemplation, and that steps were being taken to carry it into execution.

There were some stations in very exposed situations where ships were particularly liable to be stranded, and where it was very necessary that there should be means of speedy communication with life-saving stations. Her Majesty's Government proposed to proceed at once with the erection of wires in such places; surveys of several of these works of a pressing

Digitized by Google

kind were in progress, and something would be immediately commenced. In addition to this, a rough estimate had been made of the cost of establishing telegraphic communication with lighthouses and lightships, which came to about £300,000.

The hon. member for East Norfolk spoke about this country being so far behind other nations in the matter of electric communication with lighthouses and life-saving stations; for his own part he did not think that we were so far behind as was commonly supposed. In the first place, a great many of our coastguard stations were already in communication with a telegraph station, and very many more were close to one. Her Majesty's Government, however, would not think of what other nations did. Great Britain was the greatest maritime nation, and therefore there was every intention on the part of the Government to meet this claim that all important points on the coast should be connected with life-saving stations. His hon. friend asked in his motion for the appointment of a Commission to inquire into the desirability of connecting outlying lights with the shore. That was not so easy a matter. He argued from a return he had got from foreign countries in which such connection had been tried—every device had been tried; but one after the other the cables had all been destroyed by rubbing against the rocks. Her Majesty's Government were happy to assent to the motion of his hon. friend, and he earnestly hoped that they would be able to do something to save our fellow-countrymen in future years from the sad fate which had befallen so many in the past.

The motion was agreed to.

LEGAL INTELLIGENCE.

The English and Scottish Investment Company v. Brunton.

Judgment in this action was delivered by Mr. Justice Charles on Tuesday last. The case was argued some time back before his lordship, when judgment was reserved. It was an interpleader issue to try the right to a sum of money claimed by both parties in the following circumstances:—The Electrical Engineering Corporation (Limited) carried on business in premises at West Drayton. These premises they insured with the Sun Fire Office, and a fire having occurred in January, 1891, a sum of over £1,809 was admitted to be due, in respect of the said fire, to them. The Corporation prior to the insurance had created and issued debentures which gave a floating charge over the whole undertaking, and contained a clause under which the Corporation undertook not to mortgage or charge any part of their property so as to give priority over the debentureholder. The fire having occurred the Corporation were in need of money, and applied to the plaintiff Company for an advance on the security of the moneys payable by the Sun Insurance Office. The money was advanced under the circumstances as found by the learned Judge's judgment, and the question was whether the plaintiffs were affected by constructive notice of the existence of the condition in the debenture prohibiting the creation of prior mortgages and charges.

His LORDSHIP delivered a written judgment, going fully into the particulars of the flotation of the Electrical Engineering Corporation, quoting largely from the Articles of Association, and setting out the particular form of the debenture certificate. He said that the case involved some difficult and intricate points, and in the result found for the plaintiffs with costs. A very full report of the judgment, which had no technical interest for readers of *The Electrician*, appeared in *The Times* of Wednesday.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).

The following report of the Directors of this Company will be presented to the fifth ordinary general meeting, to be held on Friday, the 6th May, at Winchester House, E.C., at 12 o'clock:—

During the year the Company has been steadily extending its system of underground cables, and, except in certain of the outlying portions of the Company's areas, all the more important thoroughfares are provided with mains. The Directors are pleased to report that all the Company's stations have worked satisfactorily. The generating station for the Paddington district, which has been in course of construction during the past few months, will be completed almost immediately.

The expenditure upon works of construction during the year has been £113,583, making a total capital expenditure to the 31st December, 1891, of £486,926. This practically absorbs the Company's capital. Additional capital is required for the completion and equipment of the Paddington installation, supplying a wealthy and important district, which the Company has been successful in securing since its incorporation. Provision may also have to be made for certain street lighting, and other contemplated extensions of supply. The Board propose to meet the outlay for these purposes by a debenture issue not exceeding £100,000. The terms of such issue are now under the consideration of the Board, and the debentures will be offered in the first instance to the shareholders.

The gross revenue for the year amounted to £43,747. 1s. 3d., including a sum of £3,027. 1s. 3d. paid by the contractors on account of expenditure incurred by the Company in working the Sardinia-street, Rathbone-place, and Manchester-square installations during the time of testing, &c. The net revenue for the year was £9,719. 19. 8d., which enables the Directors to recommend a further final dividend of 2s. per share.

The Company's lamp connection, which on the 1st January, 1891, was equivalent to 48,000 8 candle-power lamps, rose during the year to 82,000 lamps. It now amounts to 96,000 lamps, and continues steadily to increase. With this increase the percentage of net profit may be expected to grow rapidly, as there will be no corresponding increase in the fixed charges.

It is with much regret that the Board have to record the death of their colleague, Alderman Sir R. N. Fowler, Bart., M.P. The vacancy thus caused has been filled up by the appointment of Admiral of the Fleet Lord John Hay, G.C.B.

In accordance with the Articles of Association, the following Directors, viz.:—J. Denison Pender, Esq., Admiral Sir George H. Richards, K.C.B., and John Benjamin Verity, Esq., retire from the Board, and, being eligible, offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths and Co., retire, and offer themselves for re-election.

CORRESPONDENCE.

AURORA BOREALIS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have not noticed any description in the daily papers of a most remarkable display of Aurora Borealis which I witnessed on the evening of Monday, 25th instant, when walking back from a concert in Chesterfield. On coming out I observed the sky very light, and thought at first this was due to the neighbouring blast furnaces; but on getting clear of the houses, so as to see the surrounding country, I found this was not the case. About ten o'clock and lasting for about fifteen minutes, there was a complete halo, about 25° from the horizon, and from this branched long streamers remarkably distinct, clearly defined, reaching up to the zenith, and covering a sector of about 45°. Towards the east these streamers had a reddish tinge. The distinctness of the streamers gradually died down, though one in the west remained clearly outlined after the rest had merged into a general glow.

I was with a gentleman who has travelled both on sea and land a great deal, and he said he had seen as good a display in northern latitudes, but never in his life in this country.

On speaking, about 10.40 p.m., through a telephone connected by a country line, there was evidence of electrical disturbance, shown by a continuous sharp crackling in the receiver.—I am, yours, &c., LLEWELYN B. ATKINSON.

Glasgow, April 27th.

[Judging by letters which have since appeared in the daily papers the Aurora Borealis must have been visible over the greater part of the United Kingdom. We can at any rate vouch for its appearance in the north of London, and at about 9·45 the sky in the direction of Hampstead Heath looked very much as if the light of a powerful projector was being directed to the zenith. After this the glow soon died away and was scarcely discoverable at 10 p.m.—ED. *E.*]

THE ELECTRIC LIGHTING OF PRETORIA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has been drawn to your issue of February 26th last, in which you state that Messrs. Woodhouse and Rawson United, Limited, have "also prepared the plans and specifications for the lighting of Pretoria, and supervised the erection of buildings and machinery &c.;" and I am instructed to inform you that Mr. Cousens, who, I believe, is Messrs. Woodhouse and Rawson's agent in South Africa, was at first only employed by this Company in his private capacity, as consulting engineer, but ceased to hold that position some months ago. The plans and specifications necessary for the low-tension system adopted were prepared by Messrs. Crompton and Co., Limited; and the whole contract, including the supply, delivery and erection of the plant and machinery at Pretoria, has been undertaken, and is being successfully executed by them. Please insert the above correction in your next issue.—I am, yours, &c.,

THE PRETORIA LIGHTING COMPANY, LIMITED,
London, April 26, A. Moir, London Secretary.

TRADE NOTES AND NOTICES.

TENDERS INVITED.—Tenders are invited by the Dublin Corporation for the supply and erection of wires, fittings, and sundries for the electric lighting of some of the civic buildings. Specifications may be obtained at the offices of the borough surveyor, City Hall, Dublin, and at the offices of the electrical engineer, Mr. E. Manville, 39, Victoria-street, London, S.W.; and tenders must be lodged with Mr. John Beveridge, Town Clerk, City Hall, Dublin, by five p.m. on May 10th.

Digitized by Google

TENDERS INVITED.—The Corporation of Southampton invite tenders for electrically lighting the Corporation Baths, Western Shore. Specifications may be had and plans may be seen, and all further particulars obtained, upon application to Mr. J. G. O. Aldridge, electrical-engineer, 9, Victoria-street, Westminster, and 23, High-street, Southampton. Sealed tenders, endorsed "Electric Lighting —Baths," must be left at the Town Clerk's office by 2 p m. on May 16th. Further particulars appear in our advertising columns.

SALE BY AUCTION.—Messrs. Wheatley Kirk, Price and Goulty announce in our advertisement columns that they will sell by auction on May 17th and 18th, the valuable electrical machinery, plant and effects pertaining to the estate of Messrs. Nicholson and Jennings and others, including two 45-unit "Goolden" dynamos and "Willans" engines combined; 20 dynamos by Brush, Siemens, and Ferranti, and others; 9 transformers, two 75 H.P. vertical compound engines by Brush Company; two Babcock-Wilcox boilers, about 150 H.P. each; 160 arc lamps, 2,600 switches, 4,000 ceiling roses 10,000 fuses 2,500 glass shades and globes 7 H.P. vertical engine, instruments, lamps, belting, cable, street lamps, shafting, pulleys and numerous other effects.

CALEDONIAN TELEPHONE COMPANY (LIMITED).—Resolutions have been passed and confirmed at meetings of the Company that it be wound up; that Mr. William Barton, accountant, of Glasgow, be the liquidator; and that the sale of the business to the National Telephone Company (Limited) be confirmed.

DEED OF ASSIGNMENT.—A deed of assignment and composition for the benefit of creditors has been executed by John Herbert Hale, electrician, 25, Stephen-street, Bristol, and "Collingwood," Nottingham-road, Bishopstow, Bristol. The deed provides for the payment of a composition of 12s. 6d. in the pound, payable 5s. on May 11th 1892, 5s. on July 11th, and 2s. 6d. on January 11th, 1893, secured by a surety. The trustee under the deed is Mr. James Milne, chartered accountant, Albion Chambers, Bristol. The unsecured liabilities are returned at £876. 0s. 6d., and the net assets are estimated at £615. 14s. 3d.

BANKRUPTCY, &c.—Frederick George Williams, trading at Crown Point, Denton, as an electrical engineer, under the style of Kenyon and Co., has been adjudicated a bankrupt.

MESSRS. DE FERRANTI, PATIN AND CO.—This Company, with offices in Paris, which was formed to work in France and Belgium the various patents of Mr. S. Z. de Ferranti, is being wound up, it being, we understand, Mr. de Ferranti's intention to himself exploit his patents in France.

MESSRS. GOOLDEN, ATKINSON, AND BIGGE.—In consequence of the large number of orders received from the Continent for mining machinery, Messrs. Goolden, Atkinson, and Bigge have opened a Continental office at 39, Rue Henri Maus, Brussels. This office, which was opened early in April, is under the direction of M. Pierre Chévenet, from whom every information may be obtained with regard to the long-distance transmission of power, and the special coal-cutting and other machinery supplied by this firm.

ISLE OF MAN INTERNATIONAL EXHIBITION.—This Exhibition is to be held at Douglas from July to September this year, and is to be lighted throughout by electricity. Having in view the probability that the Exhibition will be the first of a series to be held in the same buildings, the promoters have determined to make the electric light installation a permanency. The contract is in the hands of the Brush Electrical Engineering Company (Limited), who undertake to have everything in readiness by July 4th.

COUNTRY HOUSE LIGHTING.—Messrs. Drake and Gorham are engaged in fitting up Viscount Cantelupe's new house at Bexhill with the electric light. The power is to be obtained from a gas engine placed in an adjacent farm.

PRIESTMAN'S OIL ENGINE.—Messrs. Priestman Brothers (Ltd.) are issuing illustrated particulars showing their oil engines adapted to many varieties of use, from the portable agricultural engine to the high-speed electric light engine used by the Victorian Government.

PERSONAL.—Mr. John Hamilton Ward having resigned the management of the Electrical Engineering Company of Ireland (Limited), was entertained by the chief officers of the Company at a farewell supper, held at the Grosvenor Hotel, on Saturday, the 23rd inst., to bid him good-bye, and express their appreciation of him, and of the cordial relations which always existed between himself and the staff.

——— Mr. A. A. Davis undertakes the duties of manager of the above Company, in addition to those of secretary, and Mr. Arthur Handley, A.I.E.E., lately assistant engineer, becomes assistant electrical manager.

CHICAGO EXHIBITION, 1893.—The Royal Commission (Society of Arts, Adelphi, London, W.C.) announce that NO CHARGE will be made for space in the British Section of the above Exhibition.

SMOKING CONCERT.—On Friday evening last a smoking concert was held by the staff of Messrs. W. T. Goolden and their friends, at the "Swallow," Swallow-street, Piccadilly. In the unavoidable absence of Mr. W. T. Goolden, the chair was taken by Mr. Llewelyn B. Atkinson. A large company was assembled, and a most enjoyable evening was spent.

COMPANIES' MEETINGS & REPORTS.

Indo-European Telegraph Company (Limited).

The twenty-fifth ordinary general meeting of the members of this Company took place on Wednesday, at Winchester House, Old Broad-street, under the presidency of Mr. J. Herbert Tritton.

The MANAGING DIRECTOR (Mr. W. S. Andrews) read the notice convening the meeting, and the common seal was affixed to the register of members. The report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, I have to move that the report and accounts be received and adopted, and that the dividend mentioned therein be declared. In doing so I am glad to find that there is very little for me to comment upon, because prosperity does not call for commentaries, and the year just passed has, on the whole, been a favourable one for us. The receipts are increased by £2,891. 19s. 2d., and the number of words exchanged with India for the first time exceeds by 40,390 words the number of words exchanged before the reduction in the rates applied in 1886; although, as yet, the money earned is still less by £39,521 than it would have been had not the rate been reduced. The expenses are £61,108. 12s. 10d. on all accounts, and we are able to place £10,000 to the reserve fund, and to recommend the payment of a dividend which, with the interim dividend already paid, makes up 10 per cent. for the year. We carry forward £5,983. 15s. 4d., as against £4,168. 16s. 7d. last year. You will, perhaps, remember that at our last meeting I expressed to you my personal opinion, that the twelve months' trial, then proposed, of the reduced rates with Australia was not sufficient. Well, gentlemen, that has so turned out. We have not yet got accounts for one clear year's traffic, and it has been determined by all the parties to the agreement not to give the required notice of termination, and consequently it remains in force. As far as we can gather, the increase in the number of words sent is proving on the whole satisfactory; there is a falling-off in money receipts from messages under the reduced tariff, but that was to be expected, and the elasticity so far apparent in the business is promising. We have, of course, sustained a loss of South Russian traffic owing to the failure of the wheat trade, and the deeply to-be-regretted consequent famine. We have subscribed on behalf of the Company for the relief of the sufferers £500, which we have no doubt you will approve when it comes to be submitted at our next meeting, in the accounts for the current period. With Persia there has been increased telegraphic intercourse, by which we have benefited; and, on the whole, taking the complete range of the business, there is, as already stated, an improvement in the Company's affairs, which, I imagine, you will concur with me in finding satisfactory. The maintenance and working of the through lines of the Indian Government and of the Company continue to be perfectly satisfactory. I do not know that there is anything more to which I need advert. The best and most eloquent Chairman's speech that I know of is contained in the resolution which I am about to submit to the meeting, as follows:—

"*That the report and accounts now submitted be received and adopted, and that a dividend be and is hereby declared for the half-year ended December 31, 1891, of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. for the year, and a bonus of 20s. per share, both free of income-tax, making in all 10 per cent. for the year.*"

Mr. H. WEAVER seconded the motion.

The CHAIRMAN: If there are any remarks to be made or any questions to be asked before I put the resolution, now is the time, otherwise I will put the resolution to the meeting.

No shareholder rising to address the meeting the resolution was put, and was unanimously carried.

The CHAIRMAN: I have now to state that in accordance with the provisions of the Articles of Association Mr. Weaver and Mr. Delbrück retire, and offer themselves for re-election; and I beg to propose that these gentlemen be re-elected Directors of the Company.

Major-General G. B. TREMENHEERE, R.E., seconded the motion, which was unanimously adopted.

The CHAIRMAN: I have now to state that Messrs. Kemp, Ford and Co., the auditors, retire, and they offer themselves for re-election. As the right of electing these gentlemen is on the other side of the table, perhaps some one will propose their re-appointment, if that is the pleasure of the meeting.

Mr. H. ST. LAWRENCE SMITH proposed, and Mr. STEVENSON seconded the re-election of Messrs. Kemp, Ford and Co., and the motion was unanimously agreed to.

The CHAIRMAN: That concludes our business, and I thank you for your attendance.

Mr. STEVENSON said he thought the least they could do before separating was to pass a vote of thanks to the Chairman and Directors for their able administration of the Company's affairs. He was sorry to see so small an attendance, but the Company being so successful he presumed that the shareholders had not thought it necessary to put in an appearance.

Mr. RICHARDSON seconded the motion, and expressed his satisfaction at seeing so few shareholders present.

The resolution was carried unanimously.

The CHAIRMAN: Gentlemen, on behalf of my colleagues and myself, I beg to tender you my thanks for the resolution you have just passed, and to assure you that our best efforts will be given to maintain the prosperity of this prosperous Company.

Digitized by Google

The Oriental Telephone Company (Limited).

The twelfth ordinary annual general meeting of this Company was held on Wednesday last, Mr. William Addison presiding.

The SECRETARY (Mr. A. B. Chalmers) read the notice calling the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said: Gentlemen, in moving the adoption of the report and balance-sheet I am glad to be able to again report the continued progress of the business of the Company, although it is not as rapid as we could wish. The result of last year's working practically gives us a net income of about the same as the year before. The gross amount earned in rupees was in excess of the previous year, but owing to the low price of silver and consequent depreciation in exchange our net profits have not materially increased. Had the same rates ruled during the past as in the previous year we should have made some £500 more. The question of exchange is necessarily a very serious one for an Eastern Company, and as at present there seems little probability of any great advance in the value of silver, we must depend to a great extent upon increase of business to make up for the falling off in the value of the rupee. You will have seen from the report how we propose to deal with the amount of £11,169. 13s. 7d., the result of the year's business, including £2,250. 19s. 9d. brought forward from last year. The sum of £257. 0s. 4d. was incurred in legal and other incidental expenses by proceedings in the High Court of Chancery for the purpose of testing the correctness of the view the Directors took of the manner of declaration and distribution of the dividend. The decision of the Court was in favour of the Directors' action. However, since the issue of the report the Directors have received notice of appeal from the solicitor of the vendor shareholders against the decision of Mr. Justice Kekewich, and the meeting will understand that I cannot now make any remark upon the case. The next item of £1,466. 4s. 8d., in reduction of capital expenditure, we consider necessary and proper. We propose to add £3,000 to the reserve fund, bringing that fund up to £10,000, all invested in Consols, and consequently available at a moment's notice should any sudden emergency arise for its use. We do not think that any shareholder can object to such a sum being placed to reserve, as the whole of the reserve will not even then amount to 1s. per share on the uncalled capital of the Company. It has been the endeavour of the Board to accomplish two things, the one to arrange terms with the holders of the vendors' shares on a reasonable and equitable basis, and the other to abolish or greatly reduce the liability of 9s. on the ordinary shares upon which 11s. are paid. Difficulties hitherto insurmountable have presented themselves to hinder our endeavours, but we are yet in hopes of arriving at a satisfactory settlement. In the meantime we consider it prudent to add yearly to the reserve fund, so that, in the event of new business being undertaken, we can enter upon it without having to make a call on the shareholders. I need add nothing to what is contained in the report in reference to the Indian Companies. The Telephone Company of Egypt is still progressing, and pays its 6 per cent. on the preferred shares, the whole of which we practically hold. All the exchanges worked by your Company are kept in a state of efficiency. In respect to the shares held in subsidiary Companies by this Company, your Directors are of opinion that they are fully of the value assigned to them in the balance-sheet, viz., £91,937. 14s. 10d. In accordance with the resolution which was carried at the last general meeting that the Company's Memorandum of Association be altered so as to embrace "any business or manufacture relating to the generation, employment, or utilisation of electricity or magnetism or the apparatus connected therewith," application was made to the Court for permission, which was granted, provided the name of the Company were altered so as to show the enlarged powers of the Company; and a resolution that the name of the Company be changed to "The Oriental Telephone and Electric Company, Limited," will be submitted to this meeting. The Board wish it to be distinctly understood that although acquiring the new powers in view of the daily increasing uses to which electricity can be put, it is not their intention to rush into electrical business of a speculative or experimental character. In conclusion, I may mention that during the seven years the present Board has been in office, besides placing £10,000 to reserve fund, £10,099 has been written off in various ways and £2,750 invested in the purchase of debentures and shares in our subsidiary companies, whilst £15,050 has been paid in dividends exclusive of that we are recommending you to declare to-day. I beg now to move :—

"*That the Directors' report, together with the balance-sheet to December 31, 1891, be approved and adopted, and that a dividend at the rate of 2½ per cent., free of income-tax, for the year ended December 31, 1891, be declared on the paid-up capital of the Company.*"

Mr. B. ST. JOHN ACKERS seconded the resolution, which was carried.

Mr. ACKERS next moved :—

"*That William Addison, Esq., be re-elected a Director of the Company.*"

Commander HANNAY seconded.

The motion was carried unanimously.

The CHAIRMAN having briefly returned thanks, Mr. G. B, FROST moved, and Mr. LLOYD seconded :—

"*That Henry Grēwing, Esq., be re-elected a Director of the Company.*"

The motion was carried unanimously.

Mr. SPICER moved, and Commader HANNAY seconded :—

"*That Messrs. Deloitte, Dever, Griffiths, and Co. be re-elected auditors of the Company for the current year, and that their remuneration as such auditors be the sum of fifty guineas.*"

The motion was agreed to.

Mr. CHARLES CHESTON: Before proceeding with the special business, while I and the others have no objection to the declaration of a dividend, you will take me as protesting against the application of the dividend on the vendors' shares in the way it was applied last year, until the hearing of the appeal. I do not propose to make anything more than a protest on behalf of my clients.

The CHAIRMAN then moved, and Mr. B. ST. JOHN ACKERS seconded the following resolution :—

"*That the name of the Company be changed to* THE ORIENTAL TELEPHONE AND ELECTRIC COMPANY, LIMITED."

The motion was agreed to, and the proceedings terminated with a vote of thanks to the Chairman.

Elmore's French Patent Copper Depositing Company (Limited).

The first annual general meeting of the shareholders in this Company took place on the 22nd inst., under the presidency of Sir Richard J. Meade.

The notice convening the meeting having been taken as read,

The CHAIRMAN expressed regret that, through having a bad cold, he was unable to address them; but asked Major Jones (the Vice-Chairman) to read the remarks which he (the Chairman) had prepared. Major Jones, he added, was for many years employed in one of the most responsible departments under Messrs. Armstrong, and he had a special knowledge of manufactures of every description.

Major JONES then read the speech, in the course of which the Chairman stated:—I have much pleasure in appearing before you to-day to give you the results of our stewardship up to the end of December last, and to congratulate you on the result and future prospects of the policy which was inaugurated by your Directors, and approved by you, at the statutory general meeting, viz, that having satisfied ourselves as to the quality of the products made by the Elmore process, and the facility with which the same could be manufactured, we should follow no hesitating policy, but at once take the bold step of laying out our works on a scale commensurate with the importance of the industry. I am pleased to be able to state to you the success that this policy has attained. To-day we are in the unique position of having magnificent works already started—second to none in the world for the manufacture of this class of product—complete, and capable of turning out 300 tons a month, whilst with comparatively little outlay, and in a short space of time, we should be able to nearly double this output. Had it not been for the broad policy so strongly urged by M. Secrétan, who would not accept the general managership of the Company in France unless the works were commenced on what he calls a small, but what we call a large, scale, viz., for an output of 300 tons a month—had it not been for M. Secrétan's assurance that he was abundantly satisfied that the quality, cost, and facility of manufacture of articles under the Elmore process would turn out what he is now able to prove, we should not, at so early a stage, have taken the responsibility, which has until recently been a very great responsibility, of embarking your money in so large a factory, until we had actually been at work on a commercial scale. The responsibility we have undertaken is, however, amply compensated for by the satisfaction that we feel to-day in the successful carrying out of our policy. With regard to the accounts submitted with the Director's report, which is in your hands, these deal with capital expenditure, and there is little to say in reference to them, as they explain themselves. Some of the items will not appear in future years, whilst, with regard to the administration charges, these have naturally been heavy, as they include all charges under this head in connection with the erection of the works, which will not occur again. The expenditure in the experimental workshop at Paris has been most usefully applied to the training of engineers and workmen in the Elmore process while the factory was being erected, so as to ensure their being fit for their duties on its completion, and also to the working out all special requirements of the French trade, which has enabled us to deliver the goods in demand directly we commenced manufacturing. He afterwards referred to the proposed increase of capital, respecting which he said that the Directors recommended that the increase should consist of 100,000 shares of £2 each, of which 60,000 should now be issued as preference shares entitled to 10 per cent. dividend. No more than 60,000 shares would now be issued, and no further capital would be issued until they had proved by the actual earning of profits that the employment of this capital was advisable. M. Secrétan showed, he added, that the increased profit which would result from the employment of the further capital would be very large and out of all proportion to the additional outlay, and the cost of production would be reduced.

The CHAIRMAN then moved the following resolution :—

"*That the Directors' report and balance-sheet for the period commencing from the date of the Company's formation, viz., September 10, 1890, to December 31, 1891, now submitted to the meeting, be, and are, approved and adopted.*"

M. SECRÉTAN, at the invitation of the Chairman, then addressed the meeting, observing that he still maintained the views he expressed in his recent report, which fully set out the position of the Company. They were now producing their manufactures in a perfectly industrial and commercial manner, and all that was required to increase the production was the additional capital referred to. They were now producing eight to nine tons a week, but this would be materially increased in two or three weeks.

Major JONES then seconded the motion. He spoke of the difficulties which had had to be encountered in establishing the factory, maintaining that these were inevitable; and afterwards expressed his confidence, as an expert, in the Elmore process.

Digitized by Google

Mr. SIMPSON said that he could not help harking back to the circular of 1890, in which it was stated that they were to erect a 300-ton plant, and that £50,000 of debentures would be sufficient without calling on the shareholders again. They now, however, found that in addition to this £50,000, they were £50.000 in debt, and that there were liabilities on further contracts for unfinished work. They had heard a vast deal of what was to be, but they were still looking *in futuro* to the wonderful profits which were to come to them. He thought it would have been advisable to defer the issue of fresh capital until they had shown that they had earned a business profit.

Mr. HOLLAND also said that the shareholders could not live much longer on promises, and he desired some information as to whether the works were now paying.

Mr. WM. ELMORE, in answer to questions, made some encouraging statements relative to the working of the English Company and the Wire Company, stating that at the former the output was now from 15 to 18 tons a week, and that the profit on from two to three tons paid their expenses. The works of the Wire Company were now actually started. In regard to the operations at Dives, he thought that the samples on exhibition at the meeting spoke conclusively as to what was being done there.

Mr. GEDGE, M.P., asked why the French Company could not go on for a few weeks producing the manufactures without the issue of any further capital?

Mr. F. L. RAWSON considered that the position of the ordinary shareholders would be greatly improved by the new capital.

Mr. SCOTT, speaking as a consumer, testified to the value of the products.

Sir F. de WINTON (Chairman of the American Company), stated that the French works had been visited by one of the principal American copper brokers, who had written him a letter (which he read) stating that it seemed to him that M. Secrétan had proved the success of the Elmore process worked on a large scale.

The CHAIRMAN asked the shareholders to remember that the works at Dives had really only been one year in course of construction, and he thought that all present must allow that a vast deal had been done in bringing the factory to its present position.

The resolution was then carried; and the retiring Directors and auditors were afterwards re-elected.

On the motion of the CHAIRMAN, seconded by Major JONES, the resolution for raising the additional capital was passed, an amendment being accepted for enabling the Directors—if there were no legal objections—somewhat to modify the terms suggested in the resolution.

The usual complimentary votes closed the meeting.

The Directors' report adopted at the above meeting stated that the accompanying accounts were for the period from the date of the Company's formation on September 6, 1890, up to December 31, 1891, and that they dealt only with capital expenditure, no trading having been carried on. They showed the outlay that had been incurred on the Company's factory at Dives, including the purchase of raw material, copper, coal, &c., and in the preliminary experiments and arrangements for the commencement of manufacture. A circular explaining the reasons for the proposed increase of capital, together with a translation of M. Secrétan's report as General Manager, accompanied the Directors' report.

Sixty thousand of the new shares were placed upon the market during the week, 40,000 being reserved for allotment to existing shareholders and 20,000 offered to the public, the list of subscriptions closing yesterday (Thursday). This brings the total capital issued of the French Elmore Company to £320,000. The authorised capital is now £400,000.

Brazilian Submarine Telegraph Company (Limited).

The following is the Report of the Directors for the half year ended December 31, 1891, to be submitted to the thirty-seventh ordinary general meeting, to be held at Winchester House, Old Broad-street, E.C., on May 4th, at 12 noon :—

The revenue for the period amounted to £127,085 17s. 6d., and the working expenses to £32,496 2s. After providing £12,880 for debenture interest and sinking funds, and £1,037 7s. 4d., for income tax, there remains a balance of £80.682 8s. 2d.; to this is added £28.210 16s. 9d. brought forward from June 30th last, making a total of £108,693 4s. 11d. First and second interim dividends amounting to £39,000 have been paid, and £50,000 transferred to the reserve fund, leaving the sum of £19,893 4s. 11d. to be carried to the next account. The receipts for the half-year include the sum of £1,500 dividend to June 30, 1891, on the Company's shares in the African Direct Telegraph Company (Limited).

In accordance with the provisions for repayment of the first issue of debentures, dated July 31, 1884, 163 bonds representing £16,800 were drawn on the 11th inst., for payment at par on July 30th next. This, with the various drawings, will make a total repayment of £113,600, leaving £36,400 of the first issue of debentures outstanding.

The St. Vincent shore ends of the 1874 cables having become greatly worn by friction on the beach, they were renewed by the s.s. "Mirror" in October last. An interruption occurred on the 30th ult. in the 1874 cable of the St. Vincent-Pernambuco section near St. Vincent, arrangements were at once made for sending the s.s. "Mirror" from Gibraltar, and the repair was effected on the 9th instant.

The Duplex system of working has been satisfactorily established on the Lisbon-Madeira cable laid in 1882, and upon the Madeira St. Vincent and St. Vincent-Pernambuco cables laid in 1884, thus very materially increasing the carrying capacity of the Company's line.

The various sections of the Company's line are in good working order.

Submarine Cables Trust.

The following is the report of the Trustees, to be presented to the twenty-first ordinary annual meeting of the certificate holders, to be held at the offices of the Trust, 50, Old Broad-street, E.C., on Thursday, May 5th, at 12:30 :—

The revenue for this period, including the balance of £2,636. 15s. 9d. brought from the previous accounts, amounted to £25,436. 1s. 6d. During the past year the following coupons have been met :—

Due.	*Paid.*
April 15, 1891	£1 on account, May 15, 1891. £2 balance, October 15, 1891.
October 15, 1891.....	£3 paid, March 15, 1892.
April 15, 1892	£1. 2s. 6d., payable April 16, 1892.

The expenses of the Trust amounted to £1,186. 15s. 9d., and the payments on account of the coupons to £24,089. 12s. 6d., together £25,276. 8s. 3d., leaving a balance of £159. 13s. 3d. to be carried forward.

A table showing the original and present investments of the Trust is appended to the Trustees' report, showing that the investments remain unchanged since last year. Telegraph securities have maintained their value.

It is with regret the Trustees have to record the death of their secretary, Mr. Lewis Wells. They have appointed as his successor Mr. William Payton.

The meeting will have to elect two auditors for the current year, and Mr. John G. Griffiths and Mr. John Gane offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

SOHO ROLLING MILLS AND METAL WORKS COMPANY (LIMITED).—This Company was registered on April 16, 1892, with a capital of £35,000, in £1 shares, to acquire, take over as a going concern, and carry on in all its branches, the business of metal rollers, wire drawers, tube manufacturers, dealers, and merchants, carried on by William Wilkinson at the Soho Rolling Mills and other premises, situate in Heath-street South, in the City of Birmingham.

CAMBRIDGE UNIVERSITY AND TOWN ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of the above-named Company, made up to December 31, 1891, was filed on March 5th. The Company was registered on June 28, 1889, with a capital of £50,000, in £5 shares. At the time of making up, 8 shares had been taken, but no calls have as yet been made. No agreements have been filed.

HALIFAX AND BERMUDAS CABLE COMPANY (LIMITED).—The annual return of the above-named Company, made up to October 14, 1891, was filed on March 1st. The Company was registered on May 22, 1889, with a capital of £50,000, in £5 shares. At the time of making up, all the shares had been taken up, the full amount called, and all calls paid. (Note.—The above-mentioned return states that the whole capital has been issued as fully-paid, while the preceding returns state that the capital has been all taken up, the full amounts called, and all calls paid.)

IRISH HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED).—The annual return of the above-named Company, made up to December 31, 1891, was filed on March 15th. No general meeting was held in 1891. The Company was registered on June 26, 1889, with a capital of £100,000, divided into 19,900 ordinary and 100 founders' shares of £5 each. At the time of making up, 527 ordinary shares had been taken up, and upon each of these 10s. had been called, resulting in the payment of £202, and leaving £61. 10s. in arrear.

ISLINGTON AND GENERAL ELECTRIC SUPPLY, LIMITED (late the CAMBERWELL AND ISLINGTON ELECTRIC LIGHT AND POWER SUPPLY, LIMITED).—At an extraordinary general meeting of the Camberwell and Islington Electric Light and Power Supply (Limited), held at 17, Throgmorton-avenue, E.C., on Monday, Feb. 15 last, the following special resolutions were passed, and at a subsequent extraordinary general meeting held at the same place on Tuesday, March 1st, were confirmed :—(1) "That the name of the Company be changed to the Islington and General Electric Supply (Limited)." (2) "That the capital of the Company be reduced by cancelling the 100 founders' shares of £1 each." (3) "That the ordinary shares in the capital of the Company be consolidated in such manner that five thereof shall constitute one £5 share. (4) That the existing Articles of Association of the Company be and they are hereby repealed; and that the Articles, a copy whereof is now produced and signed by the Chairman of this meeting, be and they are hereby adopted, as the Articles of Association of the Company filed March 14, 1892). In the new Articles of Association, which were filed with the above, the number of Directors is stated to be not less than three nor more than seven. The first Directors are to be the persons appointed to the signatories to the Memorandum of Association, qualification £500. The form for the conversion of the 900 ordinary shares, of £1 each, into 180 ordinary shares, of £5 each, was also filed on March 14th. A notice, signifying the approval of the Board of Trade to the above

Digitized by Google

change of name, was filed on March 21, 1892. At an extraordinary general meeting, held at 17, Throgmorton-avenue, on Friday, April 1, 1892, a special resolution was passed, and subsequently confirmed, altering Article 79 by the substitution of 200 for 500, filed on April 23, 1892. The above-named Company was registered on June 28, 1890, with a capital of £1,000, divided into 900 ordinary and 100 founders' shares of £1 each. At the date of the last return (made up to January 4, 1892, and filed January 18th) only seven founders' shares were taken up, the original signatories being the only shareholders.

KENSINGTON COURT ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of the above-named Company, made up to March 31, 1892, was filed on the 6th inst. The Company was registered on June 5, 1886. At the time of making-up, all the shares had been taken up, the full amount called and all calls paid.

KEYS' ELECTRIC COMPANY (LIMITED).—The annual return of the above-named Company, made up to December 31, 1891, was filed on March 16th. The Company was registered on March 7, 1890, with a capital of £15,600, divided into 3,000 ordinary shares of £5 each, and 600 founders' shares of £1 each. At the time of making up all the shares had been taken up, and upon 2,700 of the ordinary shares £3. 15s. per share had been called, while upon the remaining 300 ordinary and 600 founders' shares the full amount had been called. All the calls have been paid, amounting in all to £12,225.

LAING ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of the above-named Company, made up to February 15, 1892, was filed on February 17th. The Company was registered on January 7, 1882, with a capital of £1,000.000, in £10 shares. At an extraordinary general meeting of the Company held on August 3, 1882, certain resolutions were passed, and at a subsequent meeting held on September 4, 1882, were confirmed, to the effect that the offer made for the purchase of the goodwill, patents, and all other rights and interests of the Anglo-Colonial Electric Light Company (Limited), and also all its machinery, implements, &c., for the sum of £45,000, to be paid for by fully-paid shares in the above-named Company, should be accepted, and that a similar offer for the purchase of the goodwill, patents, rights, interests, and effects of the Anglo-Colonial Electric Light Company (Limited), for the sum of £75,000, to be satisfied in a similar way should also be accepted, and agreements have been entered into to that effect. At the time of making-up, 12,007 shares had been taken up, of which 12,000 have been issued as fully-paid in accordance with the mentioned resolutions. Upon the remaining shares, the full amount has been called, but nothing has been paid.

LONDON ELECTRIC SUPPLY CORPORATION (LIMITED).—The annual return of the above-named Company, made up to April 8, 1892, was filed on April 20, 1892. The Company was registered on August 26, 1887, with a capital of £1.000,000, in £5 shares. By special resolution dated December 21, 1888, the capital was raised to £1,250.000 by the creation of 50.000 preference shares of £5 each. At the time of making up 111.000 ordinary and 49.840 preference shares had been taken up. Upon all of these the full amount has been called, resulting in the payment (including £160 paid on 160 forfeited shares) of £798,630, leaving £5,730 as yet unpaid.

NOTTINGHAM ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of the above-named Company, made up to January 4, 1892, was filed on March 4th following. The Company was registered on February 27, 1889, with a capital of £100,000, in £10 shares, of which 100 were founders' and 9,900 ordinary shares. At the time of making up, 27 founders' and 200 ordinary shares had been taken up, but no calls had been made. There are 10 shareholders, each of whom hold 20 ordinary shares and from two to four founders'. They are also the original signatories to the memorandum and articles of association. No agreement for the acquisition of contracts, plant, businesses, &c., have been filed.

PONTYPRIDD ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of the above-named Company, made up to March 28, 1892, was filed on the 23rd inst. The Company was registered on April 30, 1892, with a capital of £10,000, in £5 shares. At the time of making-up, 7 shares had been taken up, but no calls have been made.

TAYLER SMITH ELECTRIC COMPANY (LIMITED).—The statutory return of the above-named Company, made up to November 5, 1891, was filed on March 10, 1892. The Company was registered on July 21, 1891, with a capital of £6,000, divided into 300 £6 per cent. preference and 300 ordinary shares of £10 each. At the time of making up, 259 preference and 300 ordinary shares had been taken up, and all the ordinary shares had been issued as fully paid, in full satisfaction of the purchase price. Upon the remaining 259 preference shares £2. 10s. per share had been called, resulting in the payment of £647. 10s. In addition to this £610 has been paid in anticipation of calls, making a total of £1,257. 10s. paid.

TELEPHONE COMPANY OF EGYPT (LIMITED).—The annual return of the above-named Company, made up to the 19th inst., was filed on the 23rd. The Company was registered on January 30, 1883, with a capital of £100,000, divided into 16,000 preferred shares and 4,000 deferred shares of £5 each. At the time of making up, 12,071 preferred and 4,000 deferred shares had been taken up, of which 12,000 preferred and the deferred shares had been issued as fully paid in accordance with the above agreement. Upon the remaining 71 shares the full amounts have been called, resulting in the payment of £355.

WYNNE'S ELECTRIC CLOSED TUBE TRAMWAYS (LIMITED).—The annual return of the above-named Company, made up to March 12, 1889, was filed on the 4th inst. The Company was registered on July 28, 1887, with a capital of £6,000, in £100 shares, to purchase or otherwise acquire the letters patent or patent rights and privileges granted, or to be granted, to Frank Wynne, of 5, Westminster-chambers, Victoria-street, Westminster, S.W., for inventions relating to the application of electricity to the propulsion of vehicles or tramways, railways and roads, and to develop and turn to account the same. The patents sold to the Company were No. 1791, of 1883, for the United Kingdom, and No. 324,447, for the United States of America; and the following had been applied for at the time of registration:—Nos. 9,215 and 15,671, of 1886, and No. 747, of 1887, for the United Kingdom, with their corresponding patents applied for in Germany, France, and the United States. At the time of making-up (March 12, 1889), 47 of the 60 shares had been taken up, of which 32 had been issued as fully-paid in part payment of the purchase consideration. Upon the remaining shares the full amount had been called, resulting in the payment of £1,430, and leaving £70 as yet unpaid. Another annual return, made up to September 1, 1891, was also filed on the 25th inst., when the shares taken up, the calls paid, calls unpaid, and also the shareholders were exactly the same as in the preceding return. The latest annual return, made up to the 12th inst., was filed on the 25th inst. Fifty-two shares had been taken up, of which 32 had been issued as fully-paid. Upon 15 of the remaining shares the full amount had been called, and upon the remaining five shares £75 per share had been called, resulting in the payment of £1,805, and leaving £10 as yet unpaid.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended April 24th were £807, as against £784 for the corresponding period of last year, being an increase of £23. The total receipts to date, from January 1st last, amount to £13,624, against £12,514 in the corresponding period of 1891, being an increase of £1,110.

JOHANNESBURG LIGHTING COMPANY (LIMITED).—Subscriptions are invited for an issue of Seven per Cent. Mortgage Debentures of the Johannesburg Lighting Company (Limited), in bonds of £50 each. The present forms part of an authorised issue of £60.000, convertible, at the option of the holders, into ordinary shares of the Company, the bonds being repayable at par on December 31, 1901. The Company's share capital is £150,000, and the debentures are secured by a trust deed constituting a first charge on the Company's property and undertaking, the interest being payable half-yearly. Two concessions have been acquired from the Government for supplying gas and electric power in the city of Johannesburg; the term for each is 99 years. Applications should be forwarded to the African Banking Corporation, 43, Threadneedle-street, E.C., not later than Saturday next.

MADRAS ELECTRIC TRAMWAYS COMPANY (LIMITED).—The prospectus has been issued of this Company, the capital of which is £100,000, in £1 shares, payable 2s. 6d. per share on application, 2s. 6d. on allotment, the remainder being called up as required, with 28 days' notice. Shares subscribed for in India at Rs. 15 each. The objects of the Company were described in *The Electrician* of April 8th. The list of applications opened on Wednesday, and will close on Wednesday next, at 4 p.m.

SOUTH AMERICAN CABLE COMPANY (LIMITED).—In our advertisement pages will be found the prospectus of the above Company, which has been incorporated with an authorised share capital of £500.000, divided into 50,000 shares of £10 each. The present issue is for £300,000, in £10 shares, of which £100.000 will be taken by the contractors for the work to be done, leaving £200,000 of the ordinary share capital now offered for subscription. There is also offered £300,000 in Five per Cent. Mortgage Debentures of £100 each, the price of issue being £94 per cent., redeemable at par by 25 annual drawings, beginning in 1895; interest being payable on June 30th and December 31st. These debentures are secured by a First Mortgage Trust Deed over the cables and property of the Company. The object of the Company is to complete an additional telegraphic route between Europe and South America; the map accompanying the prospectus showing the chief points of connection which the cable is intended to effect. The Company's cables will be laid, under concessions from the Brazilian and French Governments, between Penambuco, in Brazil, and St. Louis, in Senegal, touching at the island of Fernando de Noronha. The term of the Brazilian concession, so far as exclusive rights are concerned, is for 25 years, after which the Company has the privilege of continuing the service subject to the right of purchase by the Government. The French concession confers permanent landing rights in Senegal for the purpose of telegraphic communication with Brazil, and enables the Company to join its cables at Senegal with those of the Spanish National Submarine Telegraph Company now laid between Senegal and the Canary Islands and between the Canary Islands and Cadiz. As Cadiz is a station of the international land wire system and of the submarine system of the Eastern Telegraph Company, the new line will thus form a direct connection between the telegraphs of South America and those of Europe and the rest of the world. The prospectus sets out particulars of the volume of cable traffic with South America, a share of which the Directors of the new Company anticipate securing, and the revenue from the various sources is expected to be not less than £85,000 a year, and, after deducting £49,000 for estimated working expenses, repairs, debenture interest, &c., it is anticipated that a sufficient balance will remain to pay 10 per cent. on the present issue of share capital. The India Rubber, Gutta Percha, and Telegraph Works Company (Limited) have contracted to lay suitable cables, and to supply all the necessary working and testing instruments, and to hand over to the new Company the Brazilian concession for the sum of £520,000, of which the above sum of £100,000 in fully paid shares forms part of the payment. Applications will be received by the National Bank of Scotland, Nicholas-lane, Lombard-street, E.C. (and at Edinburgh and all its branches), the

Digitized by Google

bankers to the Company; or by Messrs. M'Nicoll and Rogers, the brokers; or at the offices of the Company, 106, Cannon-street, E.C. On the ordinary shares £1 per share is to be paid on application, 30s. on allotment, and three payments of £2. 10s. each on May 16th, June 16th, and July 16th respectively. On the debenture issue, 10 per cent. on application, 10 per cent. on allotment, 30 per cent. on May 16th, and 44 per cent. on June 16th. The contractors guarantee the payment of the interest on the debentures until the cables are in operation. The trustees for the debenture holders are Messrs. James Robertson and Thomas Ness, Manager and Assistant-Manager of the Bank of Scotland, and an influential Board of Directors include Sir Charles Tupper, Bart., G.C.M.G., C.B.; the Hon. Henry Marsham; Sir Henry C. Mance, C.I.E., M.Inst.C.E.; John Y. Buchanan, Esq., F.R.S.; Robert Kaye Gray, Esq., M.Inst.C.E. The engineers to the Company are Messrs. Clark, Forde, and Taylor, and the secretary is Mr. J. Frayssinier. The lists of applications will be closed on Tuesday next, May 3rd, for both London and the country.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have decided to recommend dividends for the six months ended December 31st last, as follows:—6s. per share on the First and Second Preference shares and 6d. per share on the Ordinary shares. The sum of £2,123 is carried forward.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—**The traffic receipts for the week** ended April 22, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £2,516.
